CHICLANA, DE LA FRONTERA, a town of southern Spain, in the province of Cadiz, 12m. S.E. of Cadiz. Pop. (1920) 12,009. Owing to its position in the fertile, sheltered valley of the Irio, facing the Gulf of Cadiz, 3m. W., Chiclana is the centre of a great fruit and vine growing district, and is the favourite summer residence of wealthy Cadiz merchants. Its hot mineral springs also attract many visitors. About 5m. S. is Barrosa, where the British under Sir Thomas Graham (Lord Lynedoch) defeated the French under Marshal Victor, on March 5, 1811.

CHICLE or **CHICLE-GUM**, the coagulated milky juice (latex) of the sapodilla (*Sapota Achras*), a tropical American tree of the family Sapotaceae (*q.v.*). It was first brought to the United States as a substitute for rubber or balata, but since 1890 has been imported in increasing quantities, being the basic

ingredient of modern commercial chewing-gum. The latex is collected by tapping the trunk after the manner followed for gathering balata and gutta-percha (*qq.v.*); zigzag deep cuts are made to a height of 30 ft. or more up the trunk. The very viscous "milk" oozes out and runs slowly down to a receptacle placed at the base of the tree, the flow lasting about two hours and amounting at times to many quarts. The *chiclero* collects the chicle from his "walk" of trees once a day, gathering about a ton per season from 200 to 300 or more trees, which are rested from four to seven years between tappings, about 15% being lost by this treatment. The coagulated raw gum is boiled in large kettles until a water content of about 33% is attained; the semi-solid mass is then poured out on greased canvas and moulded into *marquettas* or blocks of about 25 lb. weight, which are packed for transportation in bales of four blocks each. For manufacture into chewing-gum the greyish-brown blocks are re-melted, foreign matter is removed, sugar and flavouring substances are added, and the finished product moulded and wrapped in packages. The importations of chicle from Mexico and Central America into North America in 1928 amounted to about 12,000,000 lb. and the commercial products made from it were valued at more than \$50,000,000.

CHICO, a city of Butte county (Calif.), U.S.A., 96m. N. of Sacramento, on the Southern Pacific railway. The population in 1930 was 7,961. Almonds, prunes and other fruits, alfalfa, rice and other small grains are produced in the region. The city has flour and rice mills, a dried fruit packing-house, and a creamery, and manufactures numerous articles, including electric railroad cars, packing cases, sash, doors, concrete pipe, beet-sugar, matches, brooms, soap and sheet metal. A State teachers' college and a Federal plant-introduction station are situated there. In Bidwell park is the Hooker oak, which has a diameter of 9ft. and a spread of 150ft. Lassen peak (10,465ft.), the only active volcano in the country, which had 220 eruptions between May 1914 and Jan. 1916, is 65m. N.E., in a national park of 124sq.m. Gold and silver are mined in the county, especially around Oroville, the county seat.

CHICOPEE, a city of Hampden county, Mass., U.S.A., just north of Springfield, on the east bank of the Connecticut river at the mouth of the Chicopee, and served by the Boston and Maine Railroad. It has an area of 22.9sq.m., and includes five villages: Chicopee Center, Chicopee Falls, Willimansett, Fairview and Aldenville. The population in 1920 was 36,214, of whom 12,182 were foreign-born white (4,669 from Poland); in 1930 (Federal census) 43,930. The Chicopee falls 70ft. here in less than 3m., furnishing power for numerous factories, which in 1925 had an output valued at \$87,057,326. There are two large cotton-mills (7,000 employees). Among the other leading manufactures are firearms, swords, automobiles and tyres, agricultural implements, gymnasium apparatus, and lodge regalia. The assessed valuation of property in 1927 was \$52,000,000.

Chicopee was settled about 1638; was set off from Springfield as an independent town in 1848; and was chartered as a city in 1890. The name is an Indian word meaning "cedar tree" or "birchbark place." Chicopee Falls was the home of Edward Bellamy. The bronze-casting industry (not now carried on) was founded there by Nathan Peabody Ames (1803-47), a sword-maker, who in 1836 began the manufacture of cannon-balls and church bells. Some of the finest bronze work in the country has been done here including the doors of the National Capitol.

CHICORY, *Cichorium Intybus* (family Compositae), in its wild state is a native of Great Britain, occurring most frequently in dry chalky soils and by road-sides. It has a long fleshy tap-root, a rigid branching hairy stem rising to a height of 2 or 3ft.—the leaves around the base being lobed and toothed, not unlike those of the dandelion. The flower heads are of a bright blue colour, few in number, and measure nearly an inch and a half across. Chicory is cultivated extensively on the continent of Europe—Holland, Belgium, France, Germany. Its roots roasted and ground are used as a substitute for, adulterant of, or addition to coffee; both roots and leaves are employed as salads; and the plant is grown as a fodder or herbage crop for cattle. In Great

Britain it is chiefly in connection with coffee that chicory is employed. A large proportion of the chicory root used for this purpose is obtained from neighbouring continental countries; but a considerable quantity is cultivated in England, chiefly in Yorkshire. It gives the coffee additional colour, bitterness and body.

The blanched leaves are much esteemed by the French as a winter salad, *Barbe de capucin*. In Belgium a variety of chicory called *Witloef* is preferred. There, also, the fresh roots are boiled and eaten with butter, and throughout the Continent the roots are stored for use as salads during winter.

In North America chicory is an introduced weed which has become widely distributed. It is abundant in pastures and along roadsides in the eastern United States and Canada, and is usually considered a pest. As a cultivated crop chicory is grown to some extent for its root. Chicory (French endive) is grown to some extent as a forcing crop. The roots are grown in the open during the summer and are taken up in the fall to be forced during the winter. It may be forced under greenhouse benches, in cellars or out of doors. (*See also* ENDIVE.)

CHICOUTIMI, industrial town and capital of Chicoutimi county, Quebec, Canada, on the Saguenay river (*q.v.*), 227m. N. by E. from Quebec, on the Canadian National, and Roberval and Saguenay railways; it is also connected with Quebec by regular steamship lines. Pop. (1931) 11,877. It is the centre for one of the greatest hydro developments on the North American continent: some 13 hydro power plants are either completed or under construction, with a capacity of 1,500,000 horse power. New pulp and paper developments are being carried out throughout the district.

CHIDAMBARAM, a town of British India, in the South Arcot district of Madras, 7 m. from the coast and 151 m. S. of Madras by rail. Pop. (1921) 22,501. The fine pagodas at Chidambaram are the oldest in the south of India. Here is supposed to have been the northern frontier of the ancient Chola kingdom. The principal temple is sacred to Siva, and is visited by huge numbers of pilgrims. It contains a "hall of a thousand pillars," one of numerous such halls in India, the exact number of pillars in this case being 984; each is a block of solid granite, and the roof of the principal temple is of copper-gilt. Silk cloth is manufactured in the town.

CHIEF, the head or upper part of anything, and so, in heraldry, the upper part of the escutcheon, occupying one-third of the whole (Fr. *chef*, head, Lat. *caput*). The phrase "in chief" (Med. Lat. *in capite*) is used in feudal law of the tenant who holds his fief direct from the lord paramount (*see* FEUDALISM).

CHIEF JUSTICE. In the various States of the United States there is uniformly some constitutional provision for a court of last resort, but the organization of that court varies materially. In the older States, notably those in existence at the time of the adoption of the Federal constitution, the provisions of the Constitution are very sparse in detail, though ample in scope, leaving all elaboration and the establishment of inferior courts to legislative action. In the newer States, the Constitutions frequently outline the judicial system at some length from the highest to the lowest court, leaving little to statutory enactment.

The highest court in any State is almost universally presided over by a chief justice, vested with authority over the ordering of the business of the court. His selection may follow one of several modes:—(1) In States where judges are appointed, as in Massachusetts, the chief justice is himself chosen by the appointing authority, usually the governor, who acts sometimes with the consent of the governor's council and sometimes with the advice and consent of the upper house of the legislature, as in the case of the Maryland court of appeals. (2) In a large number of States the judges are elected by the people for terms varying from 6 to 12 years, and there are regular elections of new judges at intervals shorter than the term of office, usually every two years. The chief justice in such instances is the judge whose term is most nearly at an end, providing he has not been specially appointed or elected to fill a vacancy. Thus the judge who has been longest on the court is its leader. This principle, applied sometimes in slightly different ways, is followed, for example, in

Arizona, Colorado, Idaho, Iowa, Nevada, Missouri, Pennsylvania and other States. (3) In Illinois the Supreme Court judges, after election, select one of their own number as chief justice. (4) In Florida the chief justice is selected by lot from the judges elected to the highest court.

The chief justice in the highest State courts is not only the presiding judge when the court is sitting in banc. He likewise has charge of the distribution of the work of the court among its several judges. In some States, such as California, where the State is divided into departments and the work of the judges of the court of last resort consists both in hearing cases in the various judicial departments and also in hearing cases appealed to the court sitting as a whole, the chief justice frequently has authority to apportion business among the departments, may order any cause to be heard and decided by the court in banc, and may convene the full court at any time.

In Delaware a somewhat specialized system is in operation. There a chancellor, chief justice and four associate judges are appointed by the governor with the consent of a majority of the senate. The chancellor, as the name implies, exercises a final authority over equity matters in all equity cases except those which are appealed to the court of last resort. In that event the chief justice sits with associate judges to hear the appeal, the chancellor always being absent. Where, however, law, as opposed to equity matters come before the final court, the chief justice yields his place to the chancellor, who in turn sits with the associate judges as the court of last resort. A somewhat similar differentiation between law and equity exists in New Jersey.

Through the promulgation of rules the courts of last resort in the various States frequently exercise an important regulatory power over the inferior courts, in that way marking the course of procedure in the handling of judicial business. But this regulation is normally only of the more general type and the inferior courts themselves, being more intimately acquainted with their own problems, are usually given considerable freedom in the ordering of their affairs through the establishment of their own rules.

(R. P. B.)

CHIEF RENT, the annual rent paid by the freeholders of an English manor to its lord. It is a payment which clears the freeholder from all obligations and dues to the lord of the manor. (See QUIT RENT.)

CHIEFS. Chieftainship occurs among many but not all primitive peoples at all levels of culture. Its essential feature is the fact that there is always some individual person who is regarded as the official head of the community, and who acts as its leader, ruler and representative. Almost everywhere he bears some distinctive title; and by virtue of his office he frequently enjoys special rights and privileges, and is held in a high degree of honour and appreciation by the other members of the community.

Forms of Chieftainship.—The institution varies according to the size and structure of the community. Among the lower hunting peoples, where the political unit is a small local group, there is generally only a single chief; and this is also the case even among such relatively advanced peoples as the Bantu tribes of South Africa. Elsewhere there may be found a dual chieftainship, as, e.g., under the dual organization (*q.v.*), where each moiety often has a chief of its own. Or, as among many North American and Melanesian tribes, there may be a division of functions resulting in the occurrence of two chiefs, one of whom is generally associated with the economic and religious side of tribal life, while the other is associated with the military and profane aspects. Thus, among the Mekeo peoples of New Guinea, each clan possesses two chiefs, the high chief and the war chief, while among the neighbouring Roro peoples, the high chief is associated with another, whose business it is to see that the orders of the high chief are carried out. In both cases the functions of the high chief are mainly of a sacred kind. Again, as in Polynesia and parts of Africa, where the community is divided into a number of distinct social classes, there may be several chiefs or grades of chiefs. In general, with the advance in political organization, political powers and functions are multiplied

and diversified, and this increasing complexity of duties and functions requires the existence of different grades of officers. Thus, the highly organized Iroquois and Creek of North America have civil chiefs and sub-chiefs, chosen for personal merit, and permanent and temporary war chiefs. These several grades of chiefs bear distinctive titles, indicative of their diverse jurisdiction.

In most communities the office of chief is hereditary within a certain family or group of families, so that only members of this family or group of families can become chiefs. Where inheritance is thus recognized it is almost always reckoned in the male line. The chieftainship goes only exceptionally to a woman, and then usually only in default of a suitable male successor. Female chiefs occur sporadically, especially in parts of Africa, but there is hardly a single people among whom the chiefs are regularly women. The rule of descent generally follows that of the community. Where it is patrilineal, the chief is usually succeeded by one of his sons, most frequently the eldest, but primogeniture is by no means universal. In matrilineal societies, the successor is normally a brother of the chief, or one of his sister's sons. Even where the office is thus inherited, however, the succession is often dependent upon the fulfilment of certain conditions. If the rightful heir is regarded as incompetent, or is physically unsound, or suffers from some other disability, he may be passed over. Sometimes he is required to pass through certain tests before he is allowed to take up office.

In other communities the chief is elected. Where this is the case, the choice is often determined by personal qualities or attributes, such as bravery in war, skill in hunting, fishing or some other occupation, ability in council or debate, knowledge of tribal lore and tradition, wealth, generosity, character and so on. Sometimes the chief is elected for a certain period only, as among certain North American tribes, where special war chiefs are chosen to hold office only as long as the war lasts.

Powers and Functions.—These vary considerably; in many parts of the world the office is unaccompanied by the exercise of authority or political functions; at any rate, as far as the administration of justice is concerned. This is the case especially in Oceania and America; in Africa, on the other hand, the chief is often not only the chief judge of his people, but also the law-giver. But his other activities extend over a very wide range. He is often a prominent figure in the economic life of the tribe, and directs hunting, fishing, planting, harvesting, pastoral migrations and trading, according to the mode of life of the people. In many tribes he is regarded as the owner of the tribal land, and regulates its distribution and tenure. He is generally the wealthiest man in the tribe, and often has a very definite function as a sort of tribal banker, providing his people with feasts and, if need be, with the necessities of life, in return for the tribute which they pay him. In war, he is often the actual leader, fighting at the head of the tribe, and where he is too old or too sacred to do that, he plans campaigns and creates *morale* by incantations and medicines. In a number of cases he assigns wives, manages marriages, confirms inheritances, and otherwise makes his influence felt at many junctures of family life.

The chief plays an extremely important part in the religious life of the community. He acts as priest in public rites, prayers and sacrifices; he is frequently the chief magician of his people, and is often held responsible for the weather and the crops, for the health of his subjects and the fertility of their herds. So that, especially among the more highly organized peoples, he is often regarded as sacred or even divine, both during his lifetime and after his death. There are almost always special prohibitions and obligations regulating the relations between him and his subjects, and some form of etiquette and ceremonial to be observed in approaching him. His own health and soundness are in some cases of vital importance to the community. For their sake he must observe many irksome rules of conduct and diet, neglect of which is regarded as harmful not only to himself but also to his people; and bodily weakness may render him liable to deposition and even death.

Origin.—Of the various theories put forward to explain the existence of chiefs, one of the most famous is that in which Sir

James Frazer argues that the chief developed out of the medicine man, and was primarily a magician, his juridical and other functions being a subsequent development. By Davy's theory the chieftainship arose through the concentration of wealth in the hands of one man, whose superior economic position gave him authority over the rest. Rivers, again, stresses the fact that chiefs usually have customs peculiar to themselves, frequently with a similarity between the functions of chiefs in different societies widely separated; and he therefore thinks that the strong basis of "group sentiment" in the government of early societies changes to that of individual authority by the advent of a race of rulers, "enterprising strangers," imposing their ideas upon a community, and becoming chiefs.

There is something to be said for each of these theories, but while each of them lays stress upon a factor of great importance, none of them is exclusive. There is no single factor which can be regarded as having produced chieftainship, which is probably the resultant of a whole series of different factors acting in different combinations in different parts of the world. The essential fact about chieftainship, wherever it occurs, is that it serves as a means of concentrating the activities of the community under the direction of one person. The chief is not merely the representative and leader of the community; he is also frequently the symbol of its corporate unity.

See J. G. Frazer, "The Magic Art and the Evolution of the King-ship" (*The Golden Bough*, vols. i. and ii., 1911); R. H. Lowie, *Primitive Society* (1920); G. Davy, *La Foi Jurée* (1922); W. H. R. Rivers, *Social Organisation* (1924). (I. S.)

CHIEMSEE, also called *Bayrisches Meer*, the largest lake in Bavaria, lies 1,600ft. above the sea, between the rivers Inn (to which it drains through the Alz) and Salzach. With a length of 6 and a breadth of 9m., it has an area of about 33sq.m., and contains three islands, Herrenwörth, Frauenwörth and Krautinsel. The first is beautifully wooded; it was the seat of a bishop from 1215 to 1805, until 1803 it contained a Benedictine monastery, and to-day it is remarkable for its castle. The shores of the lake are flat on the north and south sides, but its other banks are flanked by undulating hills. The waters are clear and well stocked with trout and carp; but the fishing is strictly preserved, and steamers ply on the lake.

CHIENG MAI is the capital of the Lao State of the same name and of the provincial division of Siam called Bayap. The town, enclosed by massive but decaying walls, lies on the right bank of the Me Ping, one of the branches of the Me Nam, in a plain 800ft. above sea-level, surrounded by high, wooded mountains. It has streets intersected at right angles and an enceinte within which is the palace of the Chao, or hereditary chief. The east and west banks of the river are connected by two bridges. The American Presbyterian mission, established here in 1867, has done much good educational work. Chieng Mai, which the Burmese have corrupted into Zimmé, has long been an important trade centre, resorted to by Chinese, Burmese, Shan and Siamese merchants. It is the centre of the teak trade of Siam, in which many Burmese and several Chinese and European firms are engaged. The total value of the import and export trade of the Bayap division amounts to about £2,500,000 a year. It is the headquarters of the viceroy of the north and though the hereditary chief continues as the nominal ruler, as is also the case in the other Lao States of Nan, Prè, Lampun, Napawn Lampang and Tern, which make up the division, the government is entirely in the hands of Siamese officials. The Government forest department has done good work in the division, and the conservator of forests has his headquarters in Chieng Mai. The headquarters of an army division are also situated here. French and British consuls reside at Chieng Mai, where, in addition to the ordinary law courts, there is an international court having jurisdiction in all cases in which British subjects are parties. The population, about 30,000, consists mainly of Laos, with many Shans, a few Burmese, Chinese and Siamese and some fifty Europeans. Hill Tribes (Ka) inhabit the neighbouring mountains in large numbers.

Chieng Mai was formerly the capital of a united independent

Lao kingdom which became subject to Burma and then to Siam. Later it was broken up into a number of states and has finally become a provincial division of Siam.

CHIERI, a town and episcopal see of Piedmont, Italy, province of Turin, 13m. S.E. by rail and 8m. by road from the town of Turin. Pop. (1921) 9,385 (town); 13,667 (commune). Its Gothic cathedral (1037, rebuilt 1405), is the largest in Piedmont, and has a 13th century octagonal baptistery. Subject to the bishop of Turin in the 9th and 10th centuries, it became independent in the 11th century. In 1347 it submitted voluntarily to Count Amedeus VI. of Savoy and finally came under Savoy in the 16th century. In 1785 it was made into a principality of the duke of Aosta. It was an early centre of trade and manufacture; and in the middle of the 15th century produced about 100,000 pieces of cotton goods per annum.

CHIETI, a city of the Abruzzi, Italy, the capital of the province of Chieti, and the seat of an archbishop, 140 m. E.N.E. of Rome by rail, and 9 m. W. of Castellammare Adriatico. Pop. (1921) 17,933 (town), 29,219 (commune). It is situated at a height of 1,083 ft. above sea-level, 3 m. from the railway station, from which it is reached by an electric railway. It commands a splendid view of the Apennines on every side except the east, where the Adriatic is seen. It is an active modern town, upon the site of the ancient Teate Marrucinorum, the chief town of the Marrucini. Some scanty remains of the theatre, of a temple (?) and some large reservoirs exist. The Gothic campanile of the cathedral is fine. Close by is the town hall, which contains a small picture gallery. The de Laurentiis family possesses a private collection of some importance. To the north of Chieti is the octagonal church of S. Maria del Tricaglio, erected in 1317. The order of the Theatines, founded in 1524, takes its name from the city. Under the Lombards Chieti formed part of the duchy of Benevento; it was destroyed by Pippin in 801, but was soon rebuilt and became the seat of a count. The Normans made it the capital of the Abruzzi.

CHIFFON. In dress fabrics, one of the most delicate, gauze-like and transparent of all silk tissues. Chiffon consists of a plain woven texture produced from very fine and hard-twisted warp and weft of corresponding denier (counts), with a corresponding number of warp threads and picks per inch, and a soft dull finish. So very delicate and flimsy is the chiffon texture, that it is easily distorted and pulled out of shape.

The term chiffon has different meanings in different countries. Thus, in France, it signifies a rag; in Rumania, a bleached cotton shirting; in Germany and Austria, a stout, fine, plain woven linen fabric with a smooth finish, and used for shirtings and other garments for underwear; in England, chiffon net (also nun's veiling) signifies a very fine and delicate quality of silk net used as lace and for veils. Chiffon twist signifies a hard-twisted silk thread spun with about 50 or more twists per inch, and used in the production of chiffon tissues.

CHIFFONIER, a piece of furniture differentiated from the sideboard by its smaller size and by the enclosure of the whole of the front by doors. Its name (which comes from the French for a rag-gatherer) suggests that it was originally intended as a receptacle for odds and ends which had no place elsewhere, but it now usually serves the purpose of a sideboard. It is a remote and illegitimate descendant of the cabinet; it has rarely been elegant and never beautiful. It was one of the many curious developments of the mixed taste, at once cumbrous and bizarre, which prevailed in furniture during the Empire period in England. The earliest chiffoniers date from that time; they are usually of rosewood; their "furniture" (the technical name for knobs, handles and escutcheons) was most commonly of brass, and there was very often a raised shelf with a pierced brass gallery at the back. The doors were well panelled and often edged with brass-beading, while the feet were pads or claws, or, in the choicer examples, sphinxes in gilded bronze.

CHIGI-ALBANI, a Roman princely family of Siense extraction descended from the counts of Ardenghesca. The earliest authentic mention of them is in the 13th century, and they first became famous in the person of Agostino Chigi (d. 1520), a

banker who built the palace and gardens afterwards known as the Farnesina, decorated by Raphael. Pope Julius II. made him practically his finance minister. Fabio Chigi, on being made pope (Alexander VII.) in 1655, conferred the Roman patriciate on his family, and created his nephew Agostino prince of Farnese and duke of Ariccia, and the emperor Leopold I. created the latter *Reichsfürst* (prince of the Holy Roman Empire) in 1659. In 1712 the family received the dignity of hereditary marshals of the Church and guardians of the conclaves, which gave them a very great importance on the death of every pope.

See A. von Reumont, *Geschichte der Stadt Rom*, vol. iii. (1868); *Almanach de Gotha*; V. Frittelli, *Albero genealogia della nobile famiglia Chigi* (1922).

CHIGWELL, parish and residential district of Essex, England, with stations (Chigwell Lane and Chigwell) on the L.N.E.R., 13m. N.E. of London. Pop. (1921) 2,943. The village, which figures in the Domesday survey, lies in a branch of the Roding valley, fragments of Hainault Forest lying to the south and east, bordering the village of Chigwell Row. The pleasant scenery of the neighbourhood, which attracts large numbers of visitors and residents from London, is described in Dickens's novel, *Barnaby Rudge*, and the King's Head Inn, Dickens's "Maypole," still stands. The old grammar school was founded by Samuel Harsnett, archbishop of York (d. 1631), whose fine memorial brass is in St. Mary's church, a Perpendicular structure with a Norman south door.

CHIHILI, the most north-easterly of the historic eighteen provinces of China. The name means "under direct rule," for it contains Peking which, except for a short period at the beginning of the Ming Dynasty, has been continuously the capital of China from the establishment of Mongol rule in 1280.

In 1914, however, the actual neighbourhood of Peking to a radius of about 50 miles was formed into a special administrative district and in addition, that part of Chihli, mostly mountain country, which lay beyond the Great Wall, was transferred to Inner Mongolia. These changes have reduced the area of the province of Chihli from 115,830 to 60,000 square miles. The population of the present province is estimated at approximately 30 millions. The greater part of Chihli as now constituted consists of low-lying plain shelving almost imperceptibly toward the shallow Gulf of Pe-Chihli. The surface of the plain consists of alluvium, river sands and loess, but these form only a comparatively thin cover to a sub-surface made up of infertile marine gravels. Most of the plain is, however, cultivatable and densely peopled. The winters are too cold to permit of agricultural activity and the staple foodstuffs are wheat and millet rather than rice. Only a sector of the mountain and valley country (the Si-shan or Western Hills) lying between the North China Plain and the Mongolian Plateau now remains within the province of Chihli.

The province has great strategic importance, holding the crucial passes into Mongolia and containing the vital gate of Shan-haikwan which gives access to the Manchurian plains. This has inevitably given the maritime section of Chihli great prominence in China's international relations, but except on the Kaiping coalfield (see TANGSHAN) it has been as yet little affected by the industrial developments which are transforming the life of the Yang-tze Delta.

CHIHUAHUA, a northern frontier State of Mexico, bounded N. and N.E. by the United States (New Mexico and Texas), E. by Coahuila, S. by Durango, and W. by Sinaloa and Sonora. The population in 1921 was 401,622, and the area, 94,831 sq.m. The surface of the State is in great part an elevated plain, sloping gently toward the Rio Grande. The western side, however, is much broken by the Sierra Madre and its spurs, which form elevated valleys of great fertility. An arid sandy plain extending from the Rio Grande inland for 300 to 350m. is quite destitute of vegetation where irrigation is not used. The more elevated plateaux and valleys have the heavier rainfall, but over most of the State it is less than 20in.; an impermeable clay substratum prevents its absorption by the soil, and the bare surface carries it off in torrents. The great Bolsón de Mapimi, an enclosed depression, in the south-eastern part of the State, was once con-

sidered to be an unreclaimable desert, but experiments with irrigation have shown its soil to be highly fertile. The only river of consequence is the Conchos, which flows north and north-east into the Rio Grande across the whole length of the State. In the north there are several small streams flowing northward into lakes. Agriculture has made little progress in Chihuahua, and the scarcity of water will always be a serious obstacle to its development outside the districts where irrigation is practicable. Stock-raising is an important industry in the mountainous districts of the west, where there is excellent pasturage for the greater part of the year. The principal industry of the State, however, is mining—its mineral resources including gold, silver, copper, mercury, lead, zinc and coal. The silver mines of Chihuahua are among the richest in Mexico, and include the famous mining districts of Batopilas, Chihuahuailla, Cosihuiriachic, Jesús María, Parral and Santa Eulalia or Chihuahua el Viejo. There are more than 100 of these mines, and the total annual yield at the end of the 19th century was estimated at \$4,500,000. In 1922 Chihuahua stood first among the States in the production of lead, and second in the production of silver. The State is well served by three trunk-line railways and by several short branches to the mining districts.

Chihuahua originally formed part of the province of Nueva Viscaya, with Durango as the capital. In 1777 the northern provinces, known as the Provincias Internas, were separated from the viceroyalty, and in 1786 the provinces were reorganized as intendencias, but Chihuahua was not separated from Durango until 1823. An effort was made to overthrow Spanish authority in 1810, but its leader Hidalgo and two of his lieutenants were captured and executed, after which the province remained passive until the end of the struggle. The people of the State have been active partisans in most of the revolutionary outbreaks in Mexico, and in the war of 1862-66 Chihuahua was loyal to Juárez. The principal towns are the capital Chihuahua, pop. (1921), 37,078; El Parral, 120m. S.S.E. of the State capital, in a rich mining district, with a population (1921) of 15,181; Ciudad Juárez across the Rio Grande from El Paso, pop. (1921) 19,457; Camargo, pop. (1921) 8,545; Santa Barbara, 6,847, and Jiménez, 120m. S.E. of Chihuahua, pop. (1921) 6,675.

CHIHUAHUA, a city of Mexico, capital of Chihuahua State, about 1,000m. N.W. of Mexico City and 225m. S. by E. of El Paso. Pop. (1910) 39,706; (1921) 37,078. The city stands in a beautiful valley opening northward and hemmed in on all other sides by spurs of the Sierra Madre. It is 4,635ft. above sea-level, and its climate is mild and healthy. The city is laid out regularly, with broad streets, and a handsome plaza with a monument to Hidalgo and his companions of the revolution of 1810, who were executed here. The most noteworthy of its public buildings is the fine old parish church of San Francisco, begun in 1717 and completed in 1789, one of the best specimens of 18th century architecture in Mexico. It was built, it is said, with the proceeds of a small tax on the output of the Santa Eulalia mine. Other prominent buildings are the Government palace, the Porfirio Díaz hospital, the old Jesuit college (now occupied by a modern institution of the same character), the mint, and an aqueduct built in the 18th century. Chihuahua is served by the Mexican Central, the Kansas City, Mexico and Orient and the Mexico North-western railways. Mining is the principal occupation of the surrounding district, the famous Santa Eulalia or Chihuahua el Viejo mines being about 12m. from the city. Manufacturing is making good progress, especially the weaving of cotton fabrics by modern methods. The manufacture of gunpowder for mining operations is another old industry.

Chihuahua was founded between 1703 and 1705 as a mining town, and was made a villa in 1715 with the title San Felipe el Real de Chihuahua. Because of the rich mines in its vicinity it soon became one of the most prosperous towns in northern Mexico, although the State was constantly raided by hostile Indians. In 1763 it had a population of nearly 5,000. The war of independence was followed by a period of decline, owing to political disorder and revolution, which lasted until the presidency of Gen. Porfirio Díaz. In the war between Mexico and the United States, Chihuahua was captured on March 1, 1847, by Col. A. W.

Doniphan, and again on March 7, by Gen. Price. In 1864 President Juárez made the city his provisional capital for a short time.

CHILACHAP, a port in Java, Dutch East Indies, on the south coast, in the residency of Banjumas, to the left of Schilpadden bay. Its harbour, the most favoured by nature in the whole of Java, is formed by the island of Nusa Kambangan, which is long and narrow, and lies close to the shore opposite Chilachap, beyond which it projects for a considerable distance and thus protects it from the heavy monsoon seas and swell of the Indian ocean. With the exception of Segoro Wedi bay, Chilachap is the only harbour on the south coast of Java which affords protection during the south-east monsoon, and it is the most important. The town of Chilachap, which has a population of 31,522, including 552 Europeans and Eurasians, and 1,299 foreign Asiatics, stands on a tongue of land flanked on the east by Schilpadden bay, and on the west by the estuary of the river Donan. The entrance to the harbour, which is fortified, is between a projecting headland of Nusa Kambangan and South Point, on the tongue of land opposite, and is one and a half miles wide, but owing to a sandbank, the navigable channel, which varies in depth from 29ft. to 48ft., is narrow. At present the port has two concrete wharves, 1,350ft. and 400ft. in length, respectively, affording mooring-places for vessels drawing up to 23ft. of water at low tide, and a dredging scheme is in hand which will increase the draught to 30ft. Chilachap is connected by rail with Batavia, Surabaya, Surakarta, and Samarang by a junction with the main Batavia-Surabaya line at Maos. In 1922 the total tonnage of vessels clearing from the port was 317,765. Imports and exports, respectively, were, for Chilachap in 1927, 5,460,951 and 38,776,514 guilders.

CHILAS, a hill village far up the Indus gorges in the North-West Frontier Province of India. It is dominated by a fort on the left bank of the Indus, about 50 m. below Bunji, 4,100 ft. above sea-level. It was occupied by a British force early in 1893, and was the scene of sharp fighting with local tribes. Its importance lies in its position with reference to the Kashmir-Gilgit route via Astor. It is now connected with Bunji by a metalled road. Chilas is also important from its position on a shorter route to Gilgit from the Punjab frontier than that of Kashmir and the Burzil pass. By the Kashmir route Gilgit is 400 m. from the rail-head at Rawalpindi. The Kagan route via Chilas would bring it 100 m. nearer, but the unsettled condition of the country through which the road passes has been a bar to its general use.

CHILBLAINS (or KIBÉ; *Erythema pernio*), a mild form of frostbite, affecting the fingers or toes and other parts, and causing a painful inflammatory swelling, with redness and itching of the affected part. The chief points in its aetiology are (1) the lesions occur in the extremities of the circulation, and (2) they are usually started by rapid changes from heat to cold or vice versa. The treatment is both general and local. In the general treatment, if a history of blanching fingers (fingers or hands going "dead") can be obtained, the chilblains may be regarded as mild cases of Raynaud's disease, and these improve markedly under a course of nitrites. Cardiac tonics are often helpful. Most cases improve under treatment with calcium lactate or chloride, 15 grains three times a day. Locally, ichthyol and formalin are of great value in the early congestive stage. Ichthyol, 10 to 20% in lanoline spread on linen and worn at night, often dispels an attack at the beginning. Formalin is equally efficacious, but requires more skill in its use. It can be used as an ointment, 10 to 50%, weaker for delicate skins, stronger for coarser skins. It should be replaced occasionally by lanoline. For broken chilblains a paste made from the following prescription, spread thickly on linen and frequently changed, soon cures:—Hydrarg. ammoniat. gr. v., ichthyol Mx, pulveris zinci oxidi 5iv. vaseline 3ss. Recently repeated very small doses of ultra-violet radiation have been given locally with beneficial results, but great care must be taken as the affected part reacts very readily to the rays.

CHILD, SIR FRANCIS (1642–1713), English banker, was a Wiltshire man who became a London goldsmith in 1664. In 1671 he married Elizabeth Wheeler and with his wife's step-father, Robert Blanchard (d. 1681), took over about the same

time the business of goldsmiths hitherto carried on by the Wheelers. This was the beginning of Child's Bank. Child soon gave up the business of a goldsmith and confined himself to that of a banker. He was jeweller to the king, and lent considerable sums of money to the Government. He served as sheriff of London in 1691 and as lord mayor in 1699. In 1698 he was elected M.P. for Devizes and in 1702 for the City of London, and was again returned for Devizes in 1705 and 1710. He died on Oct. 4, 1713, and was buried in Fulham churchyard. Child had twelve sons. One, Sir Robert, an alderman, died in 1721. Another, Sir Francis (c. 1684–1740), was lord mayor of London in 1732, and a director of the East India Company. He was elected M.P. for the City of London in 1722, and was member for Middlesex from 1727 until his death. After the death of the younger Sir Francis at Fulham on April 20, 1740, the banking business passed to his brother Samuel, and the bank passed to his descendants, retaining its identity until May 1924, when it was absorbed by Glyn Mills and Co.

CHILD, FRANCIS JAMES (1825–1896), American scholar and educator, was born in Boston (Mass.), Feb. 1, 1825. He graduated at Harvard in 1846, taking the highest rank in his class; was a tutor in various subjects, and after two years of study in Europe succeeded Edward T. Channing in 1851 as Boylston professor of rhetoric, oratory and elocution, and in 1876 became professor of English. Child studied the English drama and Germanic philology, the latter at Berlin and Göttingen during a leave of absence, 1849–53; and he took general editorial supervision of a large collection of the British poets. He edited Spenser (5 vols., 1855), and published an important treatise in the *Memoirs of the American Academy of Arts and Sciences* for 1863, entitled "Observations on the Language of Chaucer's Canterbury Tales." His largest undertaking, however, grew out of an original collection of *English and Scottish Ballads* (8 vols., 1857–58). He accumulated, in the university library, one of the largest folk-lore collections in existence, studied manuscript rather than printed sources, and carried his investigations into the ballads of all other tongues, meanwhile giving a sedulous but conservative hearing to popular versions still surviving. His final collection was published as *The English and Scottish Popular Ballads*, first in ten parts (1882–98), and then in five quarto volumes, which remain the authoritative treasury of their subject. Professor Child worked—and overworked—to the last, dying in Boston Sept. 11, 1896, having completed his task save for a general introduction and bibliography. A sympathetic biographical sketch was prefixed to the work by his pupil and successor George L. Kittredge. (See also F. P. Stearns, *Cambridge Sketches*, 1905.)

CHILD, SIR JOHN (d. 1690), governor of Bombay, and in fact if not in name the first governor-general of the British settlements in India, was born in London. He was sent as a little boy to his uncle, the chief of the factory at Rajapur, and in 1682 was appointed chief of the East India Company's affairs at Surat and Bombay, while at the same time his brother, Sir Josiah Child, was governor of the company at home. The two brothers showed themselves strong men and guided the affairs of the company through the period of struggle between the Moguls and Mahrattas. They have been credited by history with the change from unarmed to armed trade on the part of the company, but as a matter of fact both of them were loth to quarrel with the Mogul. War broke out with Aurangzeb in 1689, but in the following year Child had to sue for peace, one of the conditions being that he should be expelled from India. He escaped this expulsion by his death in 1690.

CHILD, SIR JOSIAH (1630–1699), English merchant, economist and governor of the East India Company, was born in London in 1630, the second son of Richard Child, a London merchant of old family. After serving his apprenticeship in the business to which he succeeded, he started on his own account at Portsmouth, as victualler to the navy under the Commonwealth, when about 25. He amassed a comfortable fortune and became a considerable stockholder in the East India Company, his interest in India being accentuated by the fact that his brother John

(*q.v.*) was making his career there. He was returned to parliament in 1659 for Petersfield; and in later years sat for Dartmouth (1673-78) and for Ludlow (1685-87). He was made a baronet in 1678. His advocacy, both by speech and by pen, under the pseudonym of Philopatris, of the East India Company's claims to political power, as well as to the right of restricting competition with its trade, brought him to the notice of the shareholders, and he became a director in 1677, and, subsequently, deputy-governor and governor. He was for a considerable time virtually the sole ruler of the company, and directed its policy as if it were his own private business. He and his brother have been credited with the change from unarmed to armed traffic; but the actual renunciation of the Roe doctrine of unarmed traffic by the company was resolved upon in Jan. 1686, under Gov. Sir Joseph Ash, when Child was temporarily out of office. He died on June 22, 1699. Child made several important contributions to the literature of economics; especially *Brief Observations concerning Trade and the Interest of Money* (1668), and *A New Discourse of Trade* (1668 and 1690). He made various proposals for improving British trade by following Dutch example, and advocated a low rate of interest as the "*causa causans* of all the other causes of the riches of the Dutch people." This low rate of interest he thought should be created and maintained by public authority. Child, whilst adhering to the doctrine of the balance of trade, observed that a people cannot always sell to foreigners without ever buying from them, and denied that the export of the precious metals was necessarily detrimental. He had the mercantilist partiality for a numerous population, and propounded a new scheme for the relief and employment of the poor; he advocated the reservation by the mother country of the sole right of trade with her colonies.

See Macaulay, *History of England*, vol. iv.; D. Macpherson, *Annals of Commerce* (1805); R. Grant, *Sketch of the History of the East India Company* (1813); B. Willson, *Ledger and Sword* (1903).

CHILD, LYDIA MARIA (1802-1880), American author and reformer, was born at Medford, Mass., Feb. 11, 1802, and died at Wayland, Mass., Oct. 20, 1880. One of the most prominent women of her day, Mrs. Child's present claims to remembrance are the contemporaneous popularity of her stories *Hobomok* (1824), *The Rebels* (1825) and *Philothea* (1836); her editorship of the *Juvenile Miscellany*, the first children's monthly periodical in the United States; and her efforts in behalf of the slaves, freedmen and Indians, including her stirring *Appeal for That Class of Americans Called Africans* (1833) and her editing of the *Anti-Slavery Standard* (1840-44) in association with her husband. In spite of the 35 editions of her *Frugal Housewife* (1829) and the German, the eight American and the 12 English editions of her *Mother's Book* (1831), these and her many other stories and books on feminism, religion, biography and history have been superseded by later works.

CHILDEBERT, the name of three Frankish kings.

CHILDEBERT I. (d. 558) was one of the four sons of Clovis. In the partition of his father's realm in 511 he received as his share the town of Paris, and the country to the north as far as the river Somme, and to the west as far as the English channel, with the Armorican peninsula. In 524, after the murder of Chlodomer's children, Childebert annexed the cities of Chartres and Orleans. He took part in the various expeditions against the kingdom of Burgundy, and in 534 received as his share of the spoils of that kingdom the towns of Mâcon, Geneva and Lyons. When Vitiges, the king of the Ostrogoths, ceded Provence to the Franks in 535, the possession of Arles and Marseilles was guaranteed to Childebert by his brothers. Childebert also made a series of expeditions against the Visigoths of Spain. In 542 he took possession of Pampeluna with the help of his brother Clotaire I., and besieged Saragossa, but was forced to retreat. From this expedition he brought back to Paris a precious relic, the tunic of St. Vincent, in honour of which he built at the gates of Paris the famous monastery of St. Vincent, known later as St. Germain-des-Prés.

He died without issue in 558, and was buried in the abbey he had founded, where his tomb has been discovered.

See "Nouveaux documents sur le tombeau de Childebert à Saint-Germain-de-Prés," in the *Bulletin de la Société des Antiquaires* (1887).

CHILDEBERT II. (570-595), king of Austrasia, was a son of Sigebert. When his father was assassinated in 575, Childebert was taken from Paris by Gundobald, one of his faithful *leudes*, to Metz, where he was recognized as sovereign. He was then only five years old, and during his long minority the power was disputed between his mother Brunhilda and the nobles. Chilperic, king at Paris, and King Gontran of Burgundy, sought alliance with Childebert, who was adopted by both in turn. But after the assassination of Chilperic in 584, and the dangers occasioned to the Frankish monarchy by the expedition of Gundobald in 585, Childebert threw himself unreservedly into the arms of Gontran. By the pact of Andelot in 587 Childebert was recognized as Gontran's heir, and with his uncle's help he quelled the revolts of the nobles and succeeded in seizing the castle of Woëvre. Many attempts were made on his life by Fredegond, who was anxious to secure Gontran's inheritance for her son Clotaire II. On the death of Gontran in 592, Childebert annexed the kingdom of Burgundy, and even contemplated seizing Clotaire's estates and becoming sole king of the Franks. He died, however, in 595. Childebert II. had had relations with the Byzantine empire, and fought in 585 in the name of the emperor Maurice against the Lombards in Italy.

CHILDEBERT III. was one of the last and feeblest of the Merovingians. A son of King Theuderich III., he succeeded his brother Clovis III. in 695, and reigned until 711.

See B. Krusch, "Zur Chronologie der merowingischen Könige," in *Forschungen zur deutschen Geschichte*, xxii. 451-490. (C. Pf.)

CHILDERIC, the name of three Frankish kings.

CHILDERIC I. (c. 437-481), king of the Salian Franks, succeeded his father Merwich (Merovech) as king about 457. With his tribe he was established around the town of Tournai, on lands which he had received as a *foederatus* of the Romans, and for some time he kept the peace with his allies. About 463, in conjunction with the Roman general Egidius, he fought against the Visigoths, who hoped to extend their dominion to the banks of the Loire; after the death of Egidius he assisted Count Paul in attempting to check an invasion of the Saxons. Paul having perished in the struggle, Childeric defended Angers against the Saxons, recovered from them the islands they had seized at the mouth of the Loire, and destroyed their forces. The Saxon chief, Odoacer, now agreed to serve the Romans and the two chieftains, now reconciled, intercepted a band of the Alamanni. These are all the facts known about him. The stories of his early life by the Franks, of his stay of eight years in Thuringia with King Basin and his wife (or sister) Basine, of his return when a faithful servant advised him that he could safely do so by sending to him half of a piece of gold which he had broken with him, and of the arrival at Tournai of Queen Basine, whom he married, are preserved by Gregory of Tours, and have found a place in French epic poetry. After the fall of the Western empire in 476 there is no doubt that Childeric regarded himself as freed from his engagements towards Rome. He died in 481 and was buried at Tournai, leaving a son Clovis (*q.v.*), afterwards king of the Franks. His tomb was discovered in 1653, when numerous precious objects, arms, jewels, coins and a ring with his name and the image of a long-haired warrior, were found.

CHILDERIC II. (c. 653-675), king of Austrasia, was a son of the Frankish king Clovis II., and in 660, although a child, was proclaimed king of Austrasia, while his brother, Clotaire III., ruled over the rest of the dominions of Clovis. After the death of Clotaire in 670 he became ruler of the three Frankish kingdoms, Austrasia, Neustria and Burgundy. He was murdered in 675 whilst hunting. He was buried at St. Germain near Paris.

CHILDERIC III. (d.c. 751), king of the Franks, was the last of the *fainéant* Merovingian kings. The throne had been vacant for seven years when the mayors of the palace, Carloman and Pippin the Short, decided in 743 to recognize Childeric as king. We cannot say whose son he was, or what bonds bound him to the Mero-

vingian family. He took no part in public business, which was directed, as before, by the mayors of the palace. When in 747 Carloman retired into a monastery, Pippin resolved to take the royal crown for himself. Childeric was dethroned in 751 and placed in the monastery of St. Omer. (C. Pf.)

Cochet, *Le Tombeau de Childeric I., roi des Francs* (1859); G. Kurth, *Histoire poétique des Mérovingiens* (1893); and E. Lavisse, *Histoire de France*, tome 6. (Paris, 1903) and authorities quoted under GREGORY OF TOURS.

CHILDERMAS: see INNOCENTS' DAY.

CHILDERS, HUGH CULLING EARDLEY (1827–1896), British statesman, was born on June 25, 1827. On leaving Cambridge he went out to Australia in 1850. In 1852 he was appointed auditor-general in Melbourne, and in 1853 collector of the customs; he carried through a bill for the establishment of the University of Melbourne, and was its first vice-chancellor. In 1856 he represented Portland in the new parliament of Victoria, and was commissioner of trades and customs in its first cabinet. In 1857 Childers returned to England as agent-general of the colony, and in 1860 entered parliament as liberal member for Pontefract. In 1865 he became financial secretary to the Treasury. He occupied various posts in the Gladstone ministries. As secretary for war from 1880 to 1882 he was responsible for the administration of the Transvaal War in 1881 and the Egyptian War in 1882. During his term of office the territorial system was introduced, with other administrative reforms of the army. From 1882 to 1885 he was chancellor of the Exchequer, and the beer and spirit duty in his budget of 1885 was the occasion of the Government's fall. In 1886 he was returned as a Home Ruler (one of the few Liberals who adopted this policy before Gladstone's conversion) for South Edinburgh, and was home secretary in Gladstone's ministry of 1886. The withdrawal of the financial clauses of the first Home Rule bill was largely due to his threat of resignation. He retired from parliament in 1892, and died on Jan. 29, 1896.

See the *Life of Childers*, by his son (1901).

CHILDERS, ROBERT CAESAR (1838–1876), English oriental scholar, son of the Rev. Charles Childers, English chaplain at Nice, studied Pāli during his residence (1860–64) as a civil servant in Ceylon. In 1869 he published the first Pāli text ever printed in England, and began to prepare a Pāli dictionary (2 vols., 1872–75), which was awarded the Volney prize by the Institute of France. In the *Journal of the Royal Asiatic Society* he published the *Mahā-parimāṇa Sutta*, the Pāli text giving the account of the last days of Buddha's life. In 1872 he was appointed sub-librarian at the India Office, and in 1873 first professor of Pāli and Buddhist literature at University college, London. He died in London on July 25, 1876.

CHILDERS, ROBERT ERSKINE (1870–1922), Irish politician, the son of Prof. Robert C. Childers of London, was educated at Haileybury and Trinity college, Cambridge. From 1895 to 1910 he was a clerk in the British House of Commons. He served as a trooper in the South African War in 1900 and from 1910 to 1914 was engaged in political work and writing for Irish Home Rule. During the World War he served in the Royal Naval Air Service and in the Royal Air Force, in which he attained the rank of major and won the D.S.C. From 1917 to 1918 he served on the secretariat of the Irish Convention. On his demobilization he returned to Ireland and was elected to Dail Eireann as deputy for Wicklow in May 1921. He was principal secretary to the Irish delegation of plenipotentiaries to Westminster, Oct.–Dec. 1921. He afterwards opposed the Anglo-Irish Treaty of 1922, supported De Valera in the Dail and joined the Republicans when they again took up arms. He was captured in Wicklow Nov. 10, 1922, and tried by military court martial on Nov. 17, on the technical charge of having possession of an automatic pistol without proper authority. He was found guilty of treason, and executed on Nov. 24, 1922.

Among his publications are: vol. v. of *The Times History of the South African War*, dealing with the guerilla campaigns; a brilliant story, *The Riddle of the Sands* (1903); *The Framework of Home Rule* (1911); *Military Rule in Ireland* (1920).

CHILD PSYCHOLOGY. General psychology is concerned chiefly with the mental life of human beings. Child psychology considers the complicated course of mental development which precedes maturity, and embraces newborn infancy as well as childhood and youth. Adolescence, the complex period of transition which begins with puberty in the early teens and extends into the middle twenties, presents important psychological problems relating to the attainment of maturity, but the term, child psychology, is ordinarily restricted largely to the pre-adolescent period.

The Problems of Child Psychology.—The central scientific problem of child psychology is the delineation and interpretation of the growth of the mind, or, in other words, of the ontogenesis of human behaviour. It is impossible to describe the child mind as though it were a fixed entity, for the gamut of growth is too wide. From the mewling infant to the whining schoolboy, "with satchel and shining morning face," the mental life of the child is changing constantly. Psychologically, it is necessary to reckon even with the behaviour differences between the four-months and the six-months old infant. Function in relation to age, the nature of individual differences in children of precisely the same age, the relations between age and maturity, are basic problems in a systematic psychology of child development.

Methods of Investigation.—The growth of the mind can be traced only by observation of the child's characteristic behaviour. There is no possibility of observing his consciousness in any immediate way, and there is meagre possibility of enlisting the child's introspection. It remains, therefore, to note scientifically the growth of behaviour itself by any or all of the following methods: (a) Naturalistic observation takes account of the child as he is in his ordinary surroundings. It reports episodes and phases of his life; or it records in a biographical manner, as in Shinn's classical notes. (b) Experimental observation limits and controls its data by devices and instrumental technique. (c) Psycho-metric and normative studies aim to define behaviour in quantitative and orientational terms so that children of varying ages, capacities and conditions may be compared through standardized tests and statistically derived norms. (d) Clinical investigation combines two or more of the above methods, and focuses intensively on selected individuals, correlating data from a variety of angles. Psycho-analysis is a special type of clinical method, which serves in some instances to reveal the psycho-genetic importance of infantile behaviour events in determining deviations in adult conduct. (e) Co-operative child research, in recent years, has developed so extensively as to deserve special mention. It is exemplified in university research centres like those at Iowa, Chicago, Minnesota, California, Yale, Berlin, Vienna and Geneva, where investigations in genetic psychology, biometrics, anthropometry and pediatrics, as well as clinical, educational and child guidance activities, are co-ordinated. There is an increasing tendency to widen the scope of child psychology so as to include all the phases of child development, and to incorporate the outlook of the medical and biological sciences, including biochemistry, developmental physiology and animal psychology. In this sense the study of child development becomes a subdivision of the science of psychology.

The Beginnings of Child Behaviour.—From the standpoint of developmental psychology, the whole life cycle is a continuum, and the growth of the mind begins with the growth of individual behaviour. Minkowski, and others, have found evidences of such behaviour throughout most of the prenatal period. Two months after conception, rudimentary body reflexes appear; the elements of the spinal reflex arc are already found in the foetus of that age. In the third month, mouth movements are evident. In the fourth, fifth and sixth months, deep cervical reflexes and labyrinth reflexes, involving head, arms and legs occur. By the seventh month most of the vital reflexes necessary for extra-uterine existence are well advanced, so that the prematurely born child has a chance of survival. There is good reason to believe that the infant of six to nine months, whether within or without the womb, is already a habit-forming creature, able to learn through processes of conditioning. Prematurity of birth does not, however, hasten the general course of the infant's behaviour growth.

GROWTH OF CHILD BEHAVIOUR FROM BIRTH TO FIRST BIRTHDAY

These pictures of a normal infant under systematic observation, were made in the photographic laboratory of The Yale Psycho-Clinic. They show characteristic behaviour patterns at advancing age levels as follows:

1. At one week of age the infant stares at large objects. Lies with head on side, extending arm on same side (tonic neck reflex; cf. 3 and 4)
2. At 6 weeks of age, lifts head when held in ventral suspension
3. At 8 weeks clasps a ring, without visual regard
4. At 12 weeks follows with eyes a small moving ball
5. At 16 weeks intently regards cube on table
6. At 20 weeks makes crude approach on spoon
7. At 24 weeks picks up cube on the table
8. At 28 weeks bangs a cube on the table
9. At 32 weeks plucks a tiny pellet
10. At 36 weeks holds two cubes and attends to a third
11. At 40 weeks explores the clapper of a bell
12. At 44 weeks secures a ring by pulling a string
13. At 48 weeks lifts a cup to secure a cube
14. At 52 weeks makes a crude imitative scribble with crayon

Sensori-motor Development.—Sensitivity to light, sound, pressure and temperature, to change of position and internal bodily conditions is present to some degree before birth. The earliest sensory responses are on a spinal and sub-cortical level, whereas well-defined sense-perceptions, with appreciation of form, space and localization, depend upon the maturation of the whole sensory apparatus, particularly the cortex, and upon the organization of habits of response through conditioning. Hearing undergoes rapid organization in the first two months, but the acquisition of visual and oculo-motor control is a long process in which horizontally moving objects are followed before vertically moving objects. There is selective regard for the human face by the fourth week. A small quarter-inch pellet is regarded as early as 20 to 24 weeks. The early sensory life of the child is probably not a "big blooming, buzzing confusion"; but the stimuli are more or less distinctly sensed as arising out of a neutral or contrasting background (Gestalt).

Although there are individual variations, sensori-motor development tends to follow orderly sequences suggested by the approximate dates which are assigned to the following items: Closing in with two hands upon a dangling object (18 weeks); picking up an object on contact (20 weeks); reaching for object on sight (24 weeks); plucking pellet with pincer prehension (40 weeks); right or left handedness partially established (40 weeks); sitting alone (9 months); walking alone (15 months); running (2 years); scribbling imitatively (1 year); scribbling spontaneously (1½ years); copying a circle (3 years), a square (5 years), a diamond (7 years). The rate of tapping (with a stylus or pencil) steadily rises from about 100 per minute at 4 years to about 250 at 12 years.

Language.—Language constitutes perhaps the most complicated of all the mental achievements of childhood. The infant begins his post-natal career with a cry, which in the first few weeks becomes differentiated for hunger, cold, discomfort. At three months, pleasure is vocalized. At four months, laughter occurs. At five months eagerness is voiced; sound play, at first solitary, later imitative and socialized, becomes increasingly channelized. Interjections and syllables like "dada" and "mama" become well defined at nine months. Heedful responsiveness to words, and adjustment to simple verbal commands or signals, follow soon after. At one year the child may have a vocabulary of three words; at two years it is nearer 300; at six years it is nearly 3,000; at twelve years it may be reckoned (Stanford-Binet scale) at over 14,000. There are large individual differences which become enormous when retarded and precocious children are compared. About 60% of two-year old children use sentences from two to eight words in length. Verbs are relatively much more frequent in the young child than the adult. Conjunctions show a slow and steady increase from two to eight years, and subordinate clauses appear before the fourth year. Piaget has shown that during the first seven years the child's speech is highly ego-centric, even his conversation having a monologue aspect. At about eight years true communication of thought becomes more characteristic and infantile notions of causality give way to more conceptual types of judgment and reasoning. Childish lying due to immaturity of the language function also tends to disappear.

Intelligence.—In a psycho-genetic sense the growth of intelligence begins early. Even the new-born child is a habit-forming creature. Conjointly through experience and maturation of his abilities, he "learns" to adapt himself to his surroundings. He learns to act to cues, sights, sounds, and to relations between things. This adaptability is the essence of that which is later called intelligence. Even before his first birthday he shows insight and can use a string as a tool to pull an attached object toward him; at two years he distinguishes between *in* and *under*; at three years he builds from a model a bridge of three blocks; at five years he defines words in terms of use; at seven years he makes a verbal distinction between a stone and an egg; and at twelve years he can define abstract words such as *envy* and *pit*. His memory span, as measured by the number of digits he can recall, increases steadily during these years. He gradually acquires notions of similarity, analogy, truth, error, causation, but his intellectual

interests are rooted in the concrete rather than the abstract. Much of his concealed thinking is more naïve and primitive than we suspect.

While the doctrine of psychological recapitulation in an extreme form is to be discredited, it has some applicability to the child's intellectual development. The child tends to follow primitive modes of thought in the early stages of his logic, and does not think merely like an undeveloped adult. Jaensch and others have demonstrated that many children have the gift of eidetic imagery, which is a capacity to reproduce vividly an object once seen and not as a transient pallid image. This natural and valuable child-like mental trait is in danger of disappearing under the influence of rationalistic culture.

Personality.—Mental growth results in a steady intensification of individuality. The new-born infant seems relatively inchoate, vegetative and unorganized; but the process of integration begins promptly and issues in a changing complex of attitudes, predispositions and habits, which constitutes his personality. The structure of this personality is the result of both intrinsic and extrinsic factors, the intrinsic ones being the organic cravings and propensities such as hunger, thirst, fear, rage and aggression, affection, imitative activity, playful, exploitive and experimental activity. Out of such general tendencies arise all sorts of emotional or instinctive seeking and avoiding responses, such as curiosity, modesty, self-display, jealousy, emulation and co-operation. Temperamental qualities, constitutional type, and endocrine characteristics, must be counted among the intrinsic factors. The actual patterns of behaviour, however, are decisively shaped by extrinsic conditioning factors through social impress, and by the action of the conditioned reflex. Psycho-analysis places stress on nutritional, sexual and presexual factors as moulding both the conscious and unconscious trends of conduct.

From the standpoint of personality, the development of the child's mind consists in the progressive attainment of emotional independence, or morale. This is a process of increasing detachment from the parental care upon which the infant is so completely dependent; hence the parent-child relationship is a key to the progress of the psychological maturity of the child. The child's mind is not a faded replica of the adult mind, but has unique characteristics which are inadequately understood. Schiller combined truth and imagination when he remarked that the adult would be a genius if he but lived up to the promise of childhood. Sincerity, directness, originality, naïve freedom from inhibition, vitality and happiness are characteristic of childhood at its best, and the mental health of the race depends upon an increasing projection of these qualities into maturity.

CHILDREN, CARE OF: see INFANCY.

CHILDREN, DISEASES OF. The study of this subject, known also as Pediatrics, is comparatively modern. There was no recognition of the need for special instruction in it as part of the curriculum at the medical schools, until, in 1899, King's College Hospital (London) appointed a physician to treat children only and to teach the students this subject. Gradually the recognition of this need has spread to other medical schools, or been forced upon them by examining bodies.

Methods of Feeding.—Infant feeding has passed through various phases. In the 17th century, when the mother was unable to suckle, wet nursing was the recognized alternative. In the 18th century hand-feeding began to replace suckling and brought with it the ills of faulty feeding; in the latter half of the 19th century the importance of infant feeding as one of the largest factors in infant mortality and diseases began to be recognized.

An attempt to replace the haphazard methods of the time was made by the introduction of percentage feeding in America. This necessitated an exact knowledge of the percentage composition of milk, cream, etc. Directions for feeding were given as a prescrip-

tion ordering the percentage of proteid, fat, and sugar, and laboratories were established in which such foods could be prepared. This method involved fallacies of theory and practice, but it encouraged more accurate and intelligent understanding of infant feeding.

A new departure is the so-called calorie feeding. The energy-producing value of a food, calculated in units of heat which the food would produce on combustion (1 calorie=heat required to heat 1 kilo of water 1° C.), determines its adequacy for the infant. At certain ages a certain number of calories per lb. weight is found to be requisite, so that food requirements can be determined by mathematical calculations. The fallacies of this method are considerable, but it is occasionally useful.

Whilst the physicians and laboratory workers were investigating the subject from the scientific standpoint, a great step forward was made by the establishment of Consultations de Nourrissons (1892) in France, and a little later of Infant Consultation Centres or Infant Welfare Centres (1906) in Great Britain and in other parts of the world. Mothers take their healthy infants to these and are instructed as to their feeding and care.

Biochemical research has shown that, besides the gross chemical composition of foods, there are subtler constituents, viz., "accessory factors" or "vitamins," which are essential to health, and, indeed, to life. (See BIOCHEMISTRY.) Related to lack of these vitamins are two diseases, infantile scurvy and rickets, the former definitely due to lack of vitamin C, the latter to deficiency of some anti-rachitic factor of which little is known.

In connection with the latter, the value of ultra-violet rays has recently been recognized; whether from sunlight, arc lamp, or mercury vapour lamp, these rays improve the general health and vigour and are beneficial in certain diseases, particularly rickets, in which they effect a rapid cure of the bone affection. To a less degree they are useful in some forms of tuberculosis. Amongst diseases affecting nutrition in infancy, congenital hypertrophy of the pylorus was formerly one of the most fatal; but now has been so successfully treated by surgery that the majority recover.

The rise of bacteriology has revolutionized our views of many diseases of children, but some still await fuller knowledge. Infantile paralysis is one of these. Flexner and his co-workers in New York, by a series of experiments on monkeys, have shown that, as had already been suspected, this disease which wrecks the lives of so many children is due to some infection, and they have investigated the conditions and ways in which it can be communicated (see SPINAL MENINGITIS). The exact nature of the virus is uncertain, but experiments have shown that infection may enter by the naso-pharynx and may probably be spread by carriers. Isolated cases occur every summer and occasionally epidemics, as in England in 1911 and in America in 1910.

The specific fevers (see INFECTIOUS FEVERS) to which children are most liable, scarlet fever, measles, chicken-pox and mumps, are still a mystery as to their exciting cause. Whooping cough, however, has been traced to a specific bacillus and a vaccine of this organism has been used extensively, but with doubtful benefit. The discovery of an antitoxin for diphtheria in 1893 led to a large reduction in the mortality from that disease; the deaths from laryngeal diphtheria fell within two years from 62% to 28%, and a few years later to 11.7%.

Tests for Diphtheria.—Various efforts have been made to immunize children against measles by serological methods and successes in this connection have been reported. The most notable advance touching specific fevers has been the Schick test for diphtheria (1913). Susceptibility to this disease can be detected by intracutaneous injection of a minute dose of the toxin of diphtheria; a slight redness or swelling at the site of infection within 24-48 hours indicates that the person showing it is susceptible. Such a means of distinguishing between children liable to infection and those who are not liable is clearly of great value when diphtheria occurs in a school or institution. As a sequel to this a new method has been introduced of conferring immunity by subcutaneous injections of a toxin-antitoxin. In this way a child found by the Schick test to be susceptible can be immunized for several months, whereas an ordinary antitoxin protects only for

a few weeks. A similar test, the Dick test, has been used to detect susceptibility to scarlet fever by the intracutaneous injection of a very dilute toxin prepared from streptococci.

There has been a striking decrease in the mortality of the specific fevers of childhood during recent years. The annual mortality in England and Wales per million persons living was in 1883: scarlet fever 1,270, measles 962, whooping cough 1,086; in 1923, scarlet fever 83, measles 508, whooping cough 399.

The effects of congenital syphilis (see VENEREAL DISEASE), first studied in detail by Diday of Lyons in 1854, have been more fully realized since the introduction of the Wassermann test (1906), in which the examination of the blood indicates the presence or absence of this disease. It may be present when no characteristic symptoms occur, indeed without symptoms of any sort.

Applied indiscriminately to children attending hospitals, this test has shown a positive result in proportions varying from 0.59% in London to 10.4% in Glasgow, but for the general child population these figures are probably too high. Syphilis causes a large waste of potential lives by miscarriages and still-births, of which there were 40% in a series of 187 pregnancies in syphilitic families, whilst of 112 live-born children in these families 33% died in infancy or early childhood. Nor does this represent the full extent of its mischief, for mental deficiency, various forms of paralysis, impaired sight, deafness, and various deformities in the child are in some instances direct or indirect results of syphilitic parentage. Of late, a wider knowledge of the effects of syphilis and its prevention and treatment in adults has reduced the frequency and severity of the inherited disease in children. The latest treatment is by subcutaneous or intravenous injections of arsenical or bismuth preparations.

Tuberculosis.—Amongst the diseases which not only account for a considerable mortality in childhood, but also add to the number of the unfit when the child grows up, are tuberculosis and rheumatism (see TUBERCULOSIS). Of children dying in hospitals about one-third have tubercle, although in some of these it is not the cause of death. Tuberculous disease of bones or joints in children is responsible for much lifelong crippling, and tuberculosis of the lungs or other organs often means at a later age years of delicacy and unfitness for the battle of life. Tuberculosis takes its heaviest toll during the first five years of life, especially in the second year, to which belong 26% of the deaths from tuberculosis in children under 12 years of age. The danger of tuberculous cow's milk has become recognized. In 1913 9.3% of samples of London milk showed tubercle bacilli. The education of the public to the danger of unboiled milk is tending to safeguard children from this infection.

Rheumatism.—Rheumatism, unlike tuberculosis, hardly ever occurs under three years of age. It affects chiefly children from 5 to 12 years of age of the hospital class, and perhaps more amongst the poorer middle class than amongst the very poor. Of children from 6 to 12 years old admitted to the medical wards of a hospital, nearly 25% were suffering from some rheumatic affection and in an out-patient department of children 5 to 12 years old 13% were attending for rheumatic troubles. Rheumatism in children affects the joints much less than in adults. Often, especially in girls, it takes the form of chorea; often the only indication is vague pain mistaken for growing pains, or perhaps a stiff neck, but however slight such manifestations the rheumatism which they indicate is specially liable in children to attack the heart. Heart disease in childhood is mostly rheumatic; sometimes it is rapidly fatal, more often after some years of invalid existence the heart gradually fails and the child dies. The duration of life in these children with rheumatic heart disease depends chiefly on the possibility of prolonged rest and careful restriction of exertion, perhaps for two or three years. Complete recovery is not impossible in some cases, and in others life may be prolonged many years in usefulness and comfort.

CHILDREN—PROTECTIVE LAWS. English law has always in theory given to children the same remedies as to adults for ill-usage, whether by their parents or by others, and has never recognized the *patria potestas* of earlier Roman law. The only points in which infancy created a defect in civil status were that infants were subject to the restraints on complete freedom of action involved in their being in the legal custody of the father, and that it was and is lawful for parents, guardians, employers and teachers to inflict corporal punishment proportional in amount and severity to the nature of the fault committed and to the age and mental capacity of the child punished. But the court of chancery, in delegated exercise of the authority of the sovereign as *parens patriae*, always asserted the right to take from parents, and if necessary itself to assume the wardship of children where parental rights were abused or serious cruelty was inflicted, the power being vested in the High Court of Justice. Abuse of the power of correction was regarded as giving a cause of action or prosecution for assault; and if attended by fatal results rendered the parent liable to indictment for murder or manslaughter.

The conception of what constitutes cruelty to children undoubtedly changed considerably with the relaxation of the accepted standard of severity in domestic or scholastic discipline and with the growth of new ideas as to the duties of parents to children.

Starting from the earlier conception, which limited ill-treatment legally punishable to actual threats or blows, the common law came to recognize criminal liability in cases where persons, bound under duty or contract to supply necessities to a child, unable by reason of its tender years to provide for itself, wilfully neglected to supply them, and thereby caused the death of the child or injury to its health, although no actual assault had been committed. Questions have from time to time arisen as to what could be regarded as necessary within this rule; and quite apart from legislation, popular opinion has influenced courts of justice in requiring more from parents and employers than used to be required. But parliament has also intervened to punish abandonment or exposure of infants of under two years, whereby their lives are endangered, or their health has been or is likely to be permanently injured (Offences against the Person Act, 1861, sec. 27), and the neglect or ill-treatment of apprentices or servants (same act, sec. 26, and Conspiracy and Protection of Property Act, 1875, sec. 6). By the Poor Law Amendment Act, 1868, parents were rendered *summarily* punishable who wilfully neglected to provide adequate food, clothing, medical aid or lodging for their children under 14 years of age in their custody.

The Acts of 1889, etc.—The chief progress in the direction of adequate protection for children prior to 1889 lay less in positive legal enactment on the subject than in the institution of an effective method of discovering and repressing cruelty punishable under the ordinary law. In the absence of any proper system of public prosecution, it is undeniable that numberless cases of neglect and ill-treatment went unpunished. The foundation of the National Society for the Prevention of Cruelty to Children by the late Benjamin Waugh met this need, and through its efforts a statute was passed in 1889 with the special object of preventing cruelty to children. This act was superseded in 1894 by a more stringent act, which was repealed by the Prevention of Cruelty to Children Act, 1904, in its turn superseded for the most part by the Children Act, 1908, which introduced many new provisions in the law relating to children and specifically dealt with the offence of "cruelty" to them. This offence can only be committed by a person over 16 in respect of a child under 16 of whom he has "custody," "charge" or "care." The act presumes that a child is in the custody of its parents, step-parents, or a person cohabiting with its parent, or of its guardians or persons liable by law to maintain it; that it is in the charge of a person to whom the parent has committed such charge (e.g., schoolmaster), and that it is in the care of a person who has actual possession or control

of it. Cruelty is defined as consisting in assault, ill-treatment, neglect, abandonment or exposure of the child in a manner likely to cause *unnecessary* suffering or injury to health, including injury to or loss of sight, hearing or limb, or any organ of the body, or any mental derangement; and the act or omission must be wilful, i.e., deliberate and intentional, and not merely accidental or inadvertent. The offence may be punished either summarily or on indictment, and the offender may be sent to penal servitude if it is shown that he was directly or indirectly interested in any sum of money payable on the death of the child, e.g., by having taken out a policy permitted under the Friendly Societies Acts. A parent or other person legally liable to maintain a child or young person will be deemed to have "neglected" him by failure to provide adequate food, clothing, medical aid or lodging, or if in the event of inability to provide such food, etc., by failure to take steps to procure the same under acts relating to the relief of the poor.

These statutes overlap the common law and the statutes already mentioned. Part of their efficacy lies in the provisions which facilitate the taking of evidence of young children, in permitting poor law authorities to prosecute at the expense of the rates, and in permitting a constable on arresting the offender to take the child away from the accused, and the court of trial on conviction to transfer the custody of the child from the offender to some fit and willing person, including any society or body corporate established for the reception of poor children or for the prevention of cruelty to children. The provisions of the acts as to procedure and custody extend not only to the offence of cruelty but also to all offences involving bodily injury to a child under 16, such as abandonment, assault, kidnapping and illegally engaging a child in a dangerous public performance.

Baby-farming.—The act of 1908 enacted more stringent provisions against baby-farming (*q.v.*). The Infant Life Protection Act of 1897 did not apply where only one child was taken, but now by the Act of 1908, where a person undertakes for reward the nursing and maintenance of one or more infants under the age of seven years apart from their parents or having no parents, he must give notice in writing to the local authority within 48 hours from the reception of the child. If an infant is already in the care of a person without reward and he undertakes to continue the nursing for reward, such undertaking is a reception of the child. The notice to the local authority must state the name, sex, date and place of birth of the infant, the name and address of the person receiving the infant and of the person from whom the infant was received. Notice must also be given of any change of address of the person having the care of the infant, or of the death of the infant, or of its removal to the care of some other person, whose name and address must also be given. It is the duty of local authorities to provide for the carrying out in their districts of that portion of the act which refers to nursing and maintenance of infants, to appoint infants' protection visitors, to fix the number of infants which any person may retain for nursing, to remove infants improperly kept, etc. Relatives or legal guardians of an infant who undertake its nursing and maintenance, hospitals, convalescent homes or institutions, established for the protection and care of infants, and conducted in good faith for religious and charitable purposes, as well as boarding schools at which efficient elementary education is given, are exempt from the provisions of the act.

The Acts of 1904 and 1908 deal with many other offences in relation to children and young persons. The Act of 1904 introduced restrictions on the employment of children which lie on the border land between cruelty and the regulation of child labour. It prohibits custodians of children from taking them, or letting them be, in the street or in public-houses to sing, play, perform or sell between 9 P.M. and 6 A.M. These provisions apply to boys under 14 and girls under 16. There are further prohibitions (1) on allowing children under 11 to sing, play, perform or be exhibited for profit, or offer anything for sale in public-houses or places of public amusement at any hour without a licence from a justice, which is granted only as to children over ten and under stringent conditions; (2) on allowing children under 16 to be

trained as acrobats, contortionists or circus performers, or for any dangerous performance; and the Children's Dangerous Performances Act, 1879, as amended in 1897, makes it an offence to employ a male young person under 16 and a female under 18 in a dangerous public performance.

The Act of 1908 renders liable to a fine not exceeding £25, or alternatively, or in addition thereto, imprisonment with or without hard labour for any term not exceeding three months, any custodian, etc., of any child or young person who allows him to be in any street, premises or place for the purpose of begging or receiving alms, or of inducing the giving of alms, whether or not there is a pretence of singing, playing, performing or offering anything for sale. An important departure in the Act of 1908 was the attempt to prevent the exposure of children to the risk of burning. Any custodian, etc., of a child under seven who allows that child to be in a room containing an open grate not sufficiently protected to guard against the risk of burning or scalding is liable on summary conviction to a fine not exceeding £10. Provision is made against allowing children between the ages of four and 16 to be in brothels; it is also made a misdemeanour if any custodian, etc., of a girl under 16 causes or encourages her seduction or prostitution, and any person having the custody of a young girl may be bound over to exercise proper care if it is shown to the satisfaction of a court of summary jurisdiction, on the complaint of any person, that she is exposed to such risk.

Tobacco and Intoxicants.—The Act of 1908, following in this particular legislation in many parts of the United States and in some of the British colonies, places a penalty on selling tobacco to any person apparently under the age of 16, whether for his own use or not. It empowers constables and park keepers to seize tobacco in the possession of any person apparently under 16 found smoking in any street or public place, as well as to search them; it also empowers a court of summary jurisdiction to prevent automatic machines for the sale of tobacco being used by young persons. The act also contains useful provisions empowering the clearing of a court whilst a child or young person is giving evidence in certain cases (*e.g.*, of decency or morality), and the forbidding children (other than infants in arms) being present in court during the trial of other persons; it places a penalty on pawnbrokers taking an article in pawn from children under 14; and on vagrants for preventing children above the age of five receiving education. It puts a penalty on giving intoxicating liquor to any child under the age of five, except upon the orders of a duly qualified medical practitioner, or in case of sickness, or other urgent cause; also upon any holder of the licence of any licensed premises who allows a child to be at any time in the bar of the licensed premises, or upon any person who causes or attempts to cause a child to be in the bar of licensed premises other than railway refreshment rooms or premises used for any purpose to which the holding of a licence is merely auxiliary, or where the child is there simply for the purpose of passing through to some other part of the premises. It makes provision for the safety of children at entertainments, and consolidates the law relating to reformatory and industrial schools, and to juvenile offenders. (See JUVENILE OFFENDERS.)

Very important provisions for the protection of children are contained in sec. 58 of the Act of 1908. This section provides that any person may bring before a juvenile court any child under 14 years of age who is found to be (a) begging in the street; (b) wandering and having no proper guardian; (c) destitute with parents, or surviving parent, in prison; (d) in the care of drunken or criminal parents; (e) the daughter of a father convicted of the carnal knowledge of any daughter under 16; (f) frequenting the company of a reported thief or prostitute; (g) living in a house frequented by prostitutes or living in circumstances likely to lead to the seduction or prostitution of the child. The duty is laid upon the police to bring such children before the court in all cases where it is in the interests of the child, unless the matter is in the hands of the education authority, or proceedings are being taken by some other person. It will be noted that the right of "any person" to invoke the aid of the juvenile court on behalf of such children is carefully preserved, but for some reason this

right is, in practice, rarely, if ever, exercised. The court before which such a child is brought may commit him either (1) to an industrial school, or (2) to the care of a relative or other fit person.

The juvenile offenders committee appointed by the home secretary has now reported (1927, p. 128) with regard to this section that the age should be raised to 17 years, that the services of probation officers should be made available and that the two following sub-sections should be added: (i.) Children and young persons under 17 who have no parents or guardians, or parents or guardians who are unfit to take care of them, or who do not exercise proper guardianship, where the court is satisfied that the children or young persons are falling into bad associations, or are exposed to moral danger or are beyond control; (ii.) children or young persons under 17 in respect of whom specified offences (such as cruelty or sexual offences) have been committed, or who are living in homes where such offences have been committed in respect of other children or young persons, and the court is satisfied that they require special protection. If this recommendation becomes law, as is probable, the two new sub-sections will practically cover all the cases set out in the existing sub-sections.

In the Act of 1908 "child" is defined as a person under the age of 14 years, and "young person" as a person who is 14 years and upwards and under the age of 16 years. The act applies to Scotland and Ireland. Legislation much on the lines of the Acts of 1889-1908 has been passed in nearly all the British dominions.

See also CHILDREN'S COURTS, EDUCATION AND LABOUR LEGISLATION. (W. F. C.; T. A. I.; W. C. HA.)

UNITED STATES

The tendency of American law has been to enlarge the rights of the child and the measure of protection afforded to him against ill-usage, exploitation and conditions affecting his health, morals and general well-being. While the laws of the various States and the judicial decisions interpreting them differ in details, certain general principles are now quite widely accepted.

The first duty of the parents of children is to provide them with support. This obligation rests principally upon the father but the mother is required to do so upon the death of the father. In recognition of the difficulty in which a widow finds herself in caring for her children and at the same time working to provide support, 39 States have passed so-called mothers' pension laws. Under these laws the mother, upon a proper showing of her own good character and the suitability of her home, may receive regular grants of money from public authority. She is thus enabled to remain in the home and care for her family. The father of step-children is not obligated to provide for them unless he voluntarily undertakes to do so. In the case of an illegitimate child, the mother is liable for its support, and she usually does not have the benefit of mothers' pensions. The father may be required to provide support if his paternity has been legally adjudged or if he voluntarily acknowledges it and assumes the duty of support. The precise extent of the duty of support is determined by the law of the particular jurisdiction. Generally it includes food, shelter, clothing, medical care and education. Compulsory education laws require the attendance of children at school and impose a penalty upon the parents for non-compliance. At the same time, child labour laws prohibit the employment of the child during the time when he is required to be in school or in dangerous occupations.

Generally speaking, the father has the control and custody of the child and he may determine where it shall live although the modern tendency is to recognize a larger right in the mother as to these matters. Either or both parents may be deprived of custody by conduct harmful to the child. In case of the father's death, the mother assumes full custody and control. An illegitimate child becomes legitimate upon the subsequent marriage of its parents. In a few States, legitimation can be effected through a judicial proceeding instituted for the purpose or through the process of legal adoption. A legitimated child assumes the same relation to the parent or parents as if born in lawful wedlock. Where a child becomes an orphan or where his parents prove to be wholly unfit to care for him properly, he may be committed in

a legal proceeding, usually through the juvenile court, to the guardianship of a suitable person, a public agency or a private philanthropic society. Guardians may be appointed either to conserve the property of the child or to provide care and maintenance, or both.

A guardian does not assume the full status of a parent. This relationship is established only through the process of legal adoption by which the child becomes the lawful child of his adoptive parents. The tendency of modern legislation is to safeguard adoption proceedings by requiring that the child shall remain in the prospective foster home for a trial period, usually six months, before the proceeding is completed. Georgia, Minnesota, New York, New Mexico, North Dakota, Ohio and Virginia have such laws. In addition, Minnesota, North Dakota, Oregon and Virginia require that some investigation of the foster home must be made by public authority and reports presented to the court having jurisdiction of the proceeding as to whether the foster parents are proper persons to adopt the child and their home a suitable one for the purpose.

Because of the abuses arising out of the casual transfer of children from parents to irresponsible people, several States have passed laws prohibiting any transfer of parental control except upon a court order; *i.e.*, through guardianship or adoption proceedings or upon order of a juvenile court. This is the law in Minnesota, North Dakota, Michigan, Alabama, Indiana, Nebraska and New Jersey. The law in many jurisdictions prohibits the bringing of children into one State from another for purposes of permanent care until after investigation and approval by the authorities of the State to which the child is brought.

In addition to the duty of support the parent must shield the child from evil surroundings and may not impose injury or cruelty upon him. The parent may use physical force to protect the child from danger and, under proper circumstances, to impose reasonable parental correction. The conduct of any adult which tends to deprave the morals of a child or endanger his health or well-being is punishable as a criminal offence.

The White House Conference on the Care of Dependent Children called by President Roosevelt in 1909 incorporated among its conclusions the following: "To engage in the work of caring for needy children is to assume a most serious responsibility, and should, therefore, be permitted only to those who are definitely organized for the purpose, who are of suitable character, and who possess, or have reasonable assurance of securing, the funds needed for their support. The only practicable way of securing this end is to require approval, by a State board of charities, or other body exercising similar powers, of the incorporation of all child caring agencies . . . ; and by forbidding other than duly incorporated agencies to engage in the care of needy children."

Ten years later the International Conference of Child Welfare Experts called by the Federal Children's Bureau declared in favour of regular inspection and licensing by public authority of privately organized and supported child caring agencies.

These pronouncements are in recognition of the duty resting upon the State to provide proper care for dependent children or to insure that only adequately equipped private organizations undertake the responsibility. Moreover, it is now clear that mere approval by the State of articles of incorporation is not sufficient. There must be regular and continuous public supervision of the work of these societies in the light of changing standards and conditions. Generally speaking, recent legislation has provided for the annual licensing and regular inspection of three types of organizations—those placing children to board or for permanent care in foster homes; institutions for dependent children, and maternity hospitals, particularly those caring for the mothers of children born out of wedlock. It is the latter type of hospital which has frequently carried on a traffic in illegitimate babies often referred to as baby farming, by which is meant the disposal of such babies to any person willing to take them and to pay the amount asked. Alabama, California, Minnesota, Missouri, North Carolina, North Dakota and Virginia have comprehensive legislation on this subject. Connecticut, Georgia, Kansas, Nebraska, New York, Ohio, South Carolina, Utah and Wisconsin deal with

the question in a variety of ways.

Child Welfare Bureaus.—The State is the ultimate guardian of all children who need what they cannot provide for themselves and what natural or legal guardians are not providing for them. To assist in the proper discharge of this obligation, laws have been enacted in several States providing for the establishment of State child welfare bureaus. The work of these bureaus varies widely and is not subject to ready classification. One of the primary objectives is to centralize and co-ordinate the child welfare work carried on by public authority. Among other activities the following are typical: securing enforcement of laws for the protection of children, child placing, special care for the feeble-minded and for children born out of wedlock, supervision of private institutions and child caring institutions, co-operation with juvenile courts and probation departments, assistance to local authorities in the administration of mothers' pensions and, finally, the promotion of good standards of child care by all organizations doing that work. Among some of the States having child welfare bureaus or departments are Alabama, California, Connecticut, Georgia, Illinois, Massachusetts, Minnesota, Missouri, New Jersey, New York, New Mexico, North Carolina, North Dakota, Oregon, Pennsylvania, Virginia, West Virginia, Wisconsin and others.

The growth of legislation for State departments has been paralleled by the creation of local county units of child welfare administration. These county boards of public or child welfare deal directly with the delinquent, dependent or neglected child in the city and surrounding rural country and usually work in close harmony with the State office. California, Minnesota, North Carolina, New Jersey and New York are the leading States which have developed this type of local organization.

Since 1911 protective legislation for children has been markedly accelerated by the work of State commissions for the study and revision of child welfare laws. This movement was no doubt stimulated in part by the British Children Act of 1908, sometimes referred to as the "Children's Magna Charta." While this Act was mainly a codification of existing law on the subject, in the process of compilation and revision distinct advance in protective measures was made. The White House Conference on the Care of Dependent Children recommended periodic review and revision of child welfare legislation. In 1911 the first State commission was appointed for this purpose. By Dec. 1923, 29 States and the District of Columbia had followed the precedent set by Ohio. In the meantime, the conferences on child welfare called by the U. S. Children's Bureau in 1919 again endorsed the principle of careful reconsideration of child welfare legislation at reasonable intervals to secure the proper co-ordination of existing law and new provisions where experience proved them to be necessary. In 1913 New Hampshire and Oregon appointed commissions; Missouri in 1915; Minnesota in 1916; Michigan and Montana in 1917; Delaware, Kansas and Wisconsin in 1918; Connecticut, Indiana, Nebraska, Oklahoma, South Dakota, South Carolina and Texas in 1919. In 1920 New York, Kentucky, Tennessee and the District of Columbia made similar provision; North Dakota, Utah and Virginia in 1921; Georgia and Maryland in 1922. In 1923 new commissions were created in Florida, Iowa and Pennsylvania. These commissions were created by legislative act or appointed by governors without specific legal authority. In all cases the governors named the members, except where *ex-officio* membership was specially provided for. The recommendations of the various commissions have been fairly widely adopted in several States. This is notably true in the State of Minnesota. Iowa, North Dakota and Pennsylvania may also be mentioned as among the States making progress in this field.

CHILDRENITE, a rare mineral species; a hydrous basic aluminium iron phosphate, orthorhombic in crystallization, found as small brilliant crystals of a yellowish-brown colour during the cutting of a canal near Tavistock in Devonshire in 1823.

CHILDREN'S AID SOCIETY, THE, an American charitable organization located in New York city. The first Children's Aid Society in America was founded in 1853 by Charles Loring Brace, "to improve the condition of poor and destitute children in the City of New York and in the State of New York." Following this children's aid societies have sprung up all over the country. As early as 1853, the society organized an industrial school for girls; free noon lunches for poor school children; the now famous newsboys' lodging house; and began placing homeless children in private family homes in the country. Penny savings banks followed in 1855; free reading rooms for boys in '59; a girls' lodging house, and mothers' meetings in '63; social centres in '68; the sick children's mission in co-operation with the New York Times in '72; a summer home for poor city children in '73; free kindergartens and circulating school libraries in '76. The first seaside sanitarium for mothers and sick infants was opened at Coney island in '84; and a fresh air cottage for crippled children was opened at Bath beach three years later. School gardens came in '94; special classes for truant and wayward boys in '97 and a free day school for crippled children in '98. What was probably the first free school dental clinic in America was established in 1906; roof playgrounds in 1909; and an open air class for anaemic children in 1911. More recent activities include an exhaustive programme of neighbourhood health development in congested slum sections. In 1923, the society undertook to place in private family homes, children whose own homes are temporarily suspended because of some family crisis, such as illness, death, divorce and desertion.

CHILDREN'S BOOKS. Children's "books" in Europe, like other books, were in use before the invention of printing. Such works as *Gesta Romanorum*, the riddles and scholastic exercises of Aelfric and Alcuin, versions of Aesop's *Fables*, etc., were all used by elder children. They are, however, a piece of social history rather than of specialized literature. The early printed (and ms.) "books of courtesy"—meant to make a boy either a "litle clergeon, seven year of age," or a squire "curteys, lowly, and servisable"—are also social documents, and may be set apart with abecedaria, horn-books, battledores and pure school-books. They lived a changed life later in works like Francis Osborne's *Advice to a Son* (1656), Halifax "the Trimmer's" *Lady's Gift* (1688), and above all in Chesterfield's *Letters*, to which the Blue-stockings provided many antidotes. The later Puritans wrote fierce moral text-books for children as children, not as nascent knights, or monks, or men of fashion. But the greatest of all Puritans was one of the first to see that something less stark was needed. John Bunyan's *Book for Boys and Girls; or, Country Rhymes for Children* (1686; later renamed *Divine Emblems*), popular for more than a century, contained rough but kindly "natural history" verses and vigorous "morals."

The Fairy Tale.—Meanwhile, oral tradition was preserving vernacular folk-lore, destined to be the bed-rock of children's literature. The lore of "rewards and fairies," in the phrase of Bishop Richard Corbet (1582-1635), is plain in Chaucer and Shakespeare, as also in the interminable mediaeval romances like *Guy of Warwick*. There was no printed version, however, before the vilely-printed chapbooks which spread over England in the late 17th and early 18th centuries—the library of Steele's little godson (*Tatler*, No. 95). But the fairy-tale invaded England from Court—Louis XIV.'s—when Perrault's *Histoires ou Contes du Temps Passé* (1696 in French, probably 1729 in Eng-

lish; better known as *Mother Goose's Fairy Tales*), and the Comtesse D'Aulnoy's tales (1707) were translated.

But this was not enough to make a literature. Other developments were needed. Isaac Watts created one with his moral but technically excellent verses. But the real beginning lay in four volumes and in the personality of one man. A few well-known rhymes had appeared incongruously in severer treatises; but the nursery-rhyme was first thoroughly collected in *Tommy Thumb's Pretty Song Book* (1744), *The Top Book of All*, *Mother Goose's Melody*, and *Gammer Gurton's Garland* (all ascribed to 1760).

The man was John Newbery, who in 1744 published his first children's book, *The Little Pretty Pocket Book*. Before his death in 1767, this friend of Goldsmith had built up a business which itself lasted into the 20th century, and had founded a new branch of the book trade. There is no space here to enumerate even the chief of his "pretty gilt toys for girls and boys" (so called from their gay Dutch-paper bindings). In form (strongly bound, not ill-printed, before long quite tolerably illustrated) as well as in substance, they decided the nature of children's books for three or four generations, even though fashion in expression changed.

The Moral Tale.—Their contents were soon influenced by wider issues than the kindly bookseller probably foresaw. Philosophy and even politics intervened. Maria Edgeworth (1767-1849), the best of all story-tellers (as such) for children, and her friend, Thomas Day (*Sandford and Merton*, 1783-89) deliberately put into nursery tales the doctrines of Rousseau. Arnaud Berquin ("l'ami des enfans") translated Day into French, and was himself translated copiously, with other French writers. The active Quakers (like Priscilla Wakefield) wrote many moral tales. Mrs. Trimmer, whose *Robins* (1786; originally called *Fabulous Histories*) remains in print on its merits as a really good story, at once combated Jacobinism, on behalf of the Church, and desired fairy-tales to be suppressed as immoral. Mrs. Sherwood, at one period almost Calvinistic in her faith in damnation, also wished to depose Titania; but her *Fairchild Family* (1818, etc.) survives—a remarkable piece of English. Ann and Jane Taylor (1804, etc.) of a notable Nonconformist family, put the "cautionary tale" into nimble verses, of which "Twinkle, twinkle, little star" will never die; with them should be associated Elizabeth Turner (1807, etc.). The Lambs, despite the glamour of their name to-day, were, in a sense, of the same school, and did not, if one is honest, do much better. Blake is splendidly apart from all tendencies.

The Return of Fantasy.—Fantasy returned in 1806, when 40,000 copies of Roscoe's *Butterfly's Ball* and Mrs. Dorset's *Peacock at Home* were sold. The tide of reaction against "amusement with instruction" came to a head in 1824, when the *German Popular Stories* of the brothers Grimm began to appear in English, with Cruikshank's illustrations. Hans Andersen was translated in 1841, levity (even naughtiness) condoned by Catherine Sinclair in *Holiday House* (1839), and absurdity made sublime by Edward Lear's *Book of Nonsense* (1840).

This new freedom infected even the infant South Kensington, and "Felix Summerly" (Sir Henry Cole, an adviser of the Prince Consort) was fain to introduce the Seven Champions and other fabulous monsters into his chaste and well-produced *Home Treasury*; an irony similar to that which had made Mary Howitt (with her industrious brother, an able purveyor of matter-of-fact) the translator of Andersen. There followed what may be called the Parley epoch, in which a number of Peter Parleys—the chief an American, S. G. Goodrich—vied in amassing instruction in easy-going form. Their output, at its best, was common-sense reasonably expressed; at its worst, the merest unctuous Gradgrindery.

Facts are known to be stubborn, and they persist for girls and boys to-day in many admirable works of popular science, often tinged by humanity, as in nature study and tales of discovery and invention. But as the substance of true children's books they were killed for ever by the two *Alice* volumes (1865 or 1866, and 1872) of Lewis Carroll (C. L. Dodgson), with whom is for ever indissolubly associated John Tenniel. Those inspired tales passed at once not only into the affections of the whole English-

speaking world, but also into its arsenal of quotations. They made possible the success of the good modern fairy-tale (the poor one is a perpetual trap for inexperienced writers), like those of Kingsley, George Macdonald and Mrs. Molesworth; of such books as Mrs. Ewing's *Lob-lie-by-the-Fire*; of the better grotesques, like the *Golliwog* books of Miss Upton; even of the magical *Peter Pan*, and of such delicate modern art as A. A. Milne's and Kenneth Grahame's.

Nothing can be said here of the illustrators, so numerous and gifted, from Bewick onwards. Nor can methods of book production be treated here, beyond the bare mention of the movable heads in books of 1810 or so, of "cut-out" (odd-shaped) books, panoramas, "rag" books, and so on; few of them are really novel to-day. Neither has it been possible to pursue into detail a most important point—the sub-division of young readers into boys, girls (*i.e.*, adolescents, each for 40 years past provided with specialist writers like Henty and Charlotte Yonge), and "children" (which includes "babies"). Lastly, the nursery has "annexed" scores of grown-up books, from *The Pilgrim's Progress* onwards.

UNITED STATES

The development of children's books in the United States follows two distinct trends:—

(1) In colonial times, England supplied her American Colonies not only with her current books for children, but with the religious, ethical and didactic ideas that entered into the first juvenile books printed in her Colonies. Since that period, the leading English books for children have continued to form the nucleus of children's libraries in the United States. Changes in British literary taste have influenced the production of the best American "juveniles." The preceding English section of this article covers this ground for the United States as well.

(2) American life and environment, the influx of foreigners from all lands, the spread of the democratic idea, the emphasis on things material and active, are developing a composite indigenous literature for American children, modified by Anglo-Saxon standards of life, language and liberty. This admixture is still in the crucible, but its component parts may easily be separated. It is chiefly this evolving "American spirit" that is discussed here.

Colonial Period to 1800.—The Puritan conception of sin and preparedness for death found expression in John Cotton's *Spiritual Milk Drawn out of the Breasts of Both Testaments, chiefly for the Spiritual Nourishment of Boston Babes in either England* (1646). This little catechism is thought to have been the first book for children printed in British colonial America. The famous *New England Primer*, "The Little Bible of New England" (*c.* 1690), combining lay instruction with religion, was issued in many editions. From time to time it changed its text, softening its religious teachings and, in revolutionary days, expressing patriotic sentiments purely American. Here we have the beginnings of the American spirit in children's books. A glance backward, before the close of the 18th century, shows us an output of small story books grim and sombre in their Puritan emphasis. About the middle of the century, Newbery's gilt toy books (*see* preceding article) were imported, and even pirated, by American booksellers, lending a lighter touch to the reading of American children. Little chap-books, probably versions of *Cinderella*, *Tom Thumb*, and other fairy tales, gave delight. In 1751, Mrs. Benjamin Franklin was ordering from London for Sally Franklin, "One good Quarto Bibel," "2 Doz. Select Tales and Fables" and other books. In 1741, little George Washington was revelling in a "pretty picture book." In 1759, Washington was ordering from his London agent, for his step-children, "6 little books for children beginning to read and a fashionable dressed baby to cost 10 shillings," and, later, two small Bibles bound in turkey and two

small prayer books. At the close of the 18th century there was a drawing away from the dismal narrative towards the tale with a stately moderated spirit of child happiness. But the new century was to bring oddly assorted groupings of American books for children, embodying changes in the American spirit.

1800-1900.—This was the American children's century. The Puritan argument that a child is a small-sized adult more prone to sin, possibly, than his parents, and that his mind should be stuffed with facts and his imagination suppressed, gradually lost its hold on education in the United States. Towards the end of the 19th century, the kindergarten movement and the impetus given child study rediscovered the play life of little children and the unfolding of their faculties, thus affecting the writing of children's books. The changes, however, were progressive. The 19th century was marked by three distinct attitudes toward child life—the religious, the didactic and the sympathetic.

The moral and religious tale of England (*see* preceding article) crossing the Atlantic, developed into a class of pious books interpreting American religious experiences. These books became an aid in the wide-spread Sunday school movement, having their outlet through the Sunday school library. Again American children were subjected to the religious controversies of their elders, and fed on a diet of reading more or less emotional and stern. A legion of inferior Sunday school books were written by authors now forgotten. There were, however, high lights in this introspective gloom. Two leading writers of the Sunday school library period were Catharine Maria Sedgwick (1789-1867) and Susan Warner (1819-1885), author of *The Wide, Wide World* (1850). Mrs. S. J. Hale (1790-1879) is remembered for her popular American nursery rhyme, "Mary had a little lamb." Towards the end of the century, the U.S. public libraries began to organize children's departments for the free distribution of juvenile books. The Sunday school libraries, unable to compete with these, died out. The advent of the children's free libraries, supported like the public schools by taxation, created a demand for books without religious teachings, books that met the changing requirements of democratic life in the United States.

At the beginning of the 19th century the instructional book was in full force, but C. C. Moore's jolly Christmas ballad, "A Visit from St. Nicholas" (1823), was followed by many happy-hearted tales. Toward the close of the century an important influence was the kindergarten movement for "children's rights," with stress on ethical instruction. Leading kindergarten writers of story-books for children were A. E. Poulsson (*In the Child's World*, 1893), Elizabeth Harrison (*In Storyland*, 1899) and K. D. Wiggin (*Birds' Christmas Carol*, 1888). Mrs. Wiggin's *Polly Oliver's Problem* (1893) had a remarkable effect. It suggested the starting of library story hours at the Carnegie library of Pittsburgh (1899), a movement which has since spread over the United States, and which has resulted in the publication of many collections of stories appropriate for telling.

This whole period produced a group of American authors whose works stand side by side with the best English books for children. In the field of verse were Alice Cary (1820-71), Phoebe Cary (1824-71), Lucy Larcom (1826-93), Eugene Field (1850-95), Celia Thaxter (1836-94), John B. Tabb (1845-1909) and J. W. Riley (1853-1916). In the field of narrative among the leaders were Nathaniel Hawthorne, *Grandfather's Chair* (1841 and 1842), *The Wonder Book* (1851), *Tanglewood Tales* (1853); Mary Mapes Dodge, *Hans Brinker; or, The Silver Skates* (1865); T. B. Aldrich, *Story of a Bad Boy* (1870); Howard Pyle, *Story of Jack Ballister's Fortunes* (1895); Brander Matthews, *Tom Paulding* (1892); F. C. Baylor, *Juan and Juanita* (1897); John Bennett, *Master Skylark* (1897). There were besides such favourite names as Frank R. Stockton (1834-1902), J. T. Trowbridge (1827-1916) and, of course, Charles Edward Carryl, who modelled his *Davy and the Goblin* (1884) after *Alice's Adventures in Wonderland*, and Joel Chandler Harris (1848-1908), who collected the Uncle Remus tales of the American negro. *Little Women* (1868; second part, 1869) by Louisa M. Alcott (1832-88) is animated by a high type of the American spirit. Miss Alcott, in her numerous volumes, added a refreshing note of human nature to children's

books. She has had many imitators. Boys' books by W. T. Adams (known as Oliver Optic, 1822-97), Horatio Alger (1832-99) and Edward S. Ellis (1840-1916), have passed under the ban of juvenile book critics, in some cases rightly, in others questionably.

Children's magazines of the 19th century stimulated the writers of American juvenile fiction. The *Juvenile Miscellany* founded by Lydia Maria Child (1826) and *The Youth's Companion* (1827) were followed by *Our Young Folks* (c. 1865), *Wide Awake* (1875), *Harper's Young People* (1879), which later became *Harper's Round Table* (1895) and *St. Nicholas*, founded in 1873 by Mary Mapes Dodge.

Brain and Brawn.—Before quitting the 19th century, one must take into account the sturdiest of American books. Their themes were drawn from pioneer and frontier days, struggles for liberty, Indian and border warfare, adventures of scouts, trappers, whalers and explorers of the vast reaches of North America. The best of these tales are rough-hewn, honest, courageous, patriotic and often reverent. James Fenimore Cooper's *The Spy* (1821) and his "Leatherstocking Series," as well as Richard Henry Dana's *Two Years Before the Mast* (1840) have been appropriated by youth. *Green Mountain Boys* by D. P. Thompson (1840) is the "classic of Vermont." C. C. Coffin's *My Days and Nights on the Battlefield* (1865), is a fine sample of numerous Civil War narratives. Among the titles reminiscent of covered wagons and other dramatic American experiences are: T. M. Reid, *The Scalp Hunters* (1851); C. C. Coffin, *Boys of '76* (1879); Noah Brooks, *Boy Emigrants* (1876) and *Boy Settlers* (1891); E. Eggleston, *The Hoosier School-Boy* (1883); H. H. Jackson, *Nelly's Silver Mine* (1878). The 19th century books of brain and brawn have many followers in the 20th, some forceful and accurate, others false and sensational. The dime and nickel novels of the 19th century have passed out of the market, largely because of high cost of book production. Their successors are equally "yellow," but more costly.

Didactic.—It is a far cry from *The New England Primer* (c. 1690) with its instruction for Protestant young America, to the modern American school reader which must satisfy Jew and gentile, Roman Catholic and Protestant, and also atheist, and which must offend no nationality that has contributed citizens to the United States. These are the demands of the modern American school book; in it the name of God is rarely mentioned, and the name of Jesus Christ is usually suppressed. The current school readers are ethically and pedagogically planned to reach the minds of mixed racial groups of children attending the public schools. The children's pleasure as well as material profit is considered in selecting the reading matter. The trend is away from the literary, as exemplified by the "Eclectic Series" of readers by W. H. McGuffey (1800-73). A vast number of instructional books are issued yearly, more pedagogically correct than their predecessors, the horn-books (see preceding article), Noah Webster's *Spelling Book* (1783), the informational books of S. G. Goodrich, known as the original Peter Parley (1793-1860), the *Lucy*, *Rollo*, *Jonas* and *Franconia* stories of Jacob Abbott (1803-79) and the biographies written by his brother, John Abbott (1805-77). The 20th century instructional books for boys and girls cover every known subject of interest to modern youth. Some of them present their subjects as projects for the young folk to work out; many of them have a sugar coating of fiction; but they steadily increase in clearness, attractiveness and informative value.

1900 and the International Mind.—The first decades of 1900 in the United States may well be called the "Reign of Youth." At the opening of the century, educators recognized the child as an individual with rights, and leaned towards the substitution of moral suasion and ethical instruction for discipline. These impulses are entering more and more into modern educational systems which encourage boys and girls to elect their own studies and to work out their problems in the school laboratories. The reaction on American story books for youth is evident. The annual output is increased. The themes of stories stress personal liberty, independent action, self-support, the benefits of education, clean athletics and outdoor life, equal rights for boys and girls;

also competition under leadership, the individual counting in the success of the group. The outstanding books of this class are well written, brisk and full of action. Some of them are noble-minded; others reflect the weaknesses of their authors. Most of them ignore things of the spirit. On the whole they are hearty and patriotic, although materialistic, and represent the best in American school life. They are offset by long series of books for both boys and girls, trashy, stereotyped or sensational, and under the ban of educators.

The American spirit is taking a vital turn, which is modifying juvenile fiction. The tides of immigration which threaten to submerge the cherished Anglo-Saxon foundation civilization of the United States are being stemmed by the public schools. In marvelous ways the schools are moulding the children of foreign-born into American citizens. There is, of course, some shift of point of view. The racially mixed people turn reminiscent eyes toward the old home. This creates an international sympathy which is welcoming translations of the best children's books of other lands. Many of these foreign tales have depth, reverence for things Christian, and simple domestic settings—wholesome ingredients in the reading of American children. Excellent examples of translations, are Hans Aanrud's *Lisbeth Longfrock* (Norwegian); Laura Fitinghoff's *Children of the Moor* (Swedish); Eugénie Foa's (pen-name of Eugénie Rebecca Rodrigues-Gradis) *Little Robinson Crusoe of Paris*, and *Mystery of Castle Pierre-fitte* (French); Hector Malot's *Nobody's Boy*, and *Nobody's Girl* (*Sans Famille*, and *En Famille*. French); Johanna Spyri's *Cornelli*, *Heidi*, *Vinzi*, and many stories of child-life (Swiss); Zacharias Topelius's *Canute Whistlewinks* (Swedish-Finnish); Dikken Zwilgmeyer's *Johnny Blossom*, and *What Happened to Inger Johanne* (Norwegian).

As said before, the American spirit in children's books is elemental and is still in the crucible. Its elements, rich and active, have been assembled from the best in the world. They promise astonishing results when once fused into a whole. But we wonder what will be the character of this national compound which is to produce a 20th century American juvenile literature of living worth.

BIBLIOGRAPHY.—See Prof. Algernon Tassin's chapter on "Books for Children," in *Cambridge History of American Literature*, vol. ii, (1918), which is brief and comprehensive and characterizes many American authors for children. O.)

CHILDREN'S COURTS or JUVENILE COURTS, a special system of tribunals for dealing with juvenile offenders, which has found its widest development in the United States. The earliest trace of such institutions is however contained in a Swiss ordinance of the year 1862. In 1869 Massachusetts adopted the same principle when a plan was introduced of hearing charges against children separately and apart from the ordinary business of the lesser tribunals. The system of "probation," by which children were handed over to the kindly care and guardianship of an appointed officer and thus escaped legal repression, was created about the same time in Boston (Mass.) and produced excellent results. The probation officer is present at the judge's side when he decides a case, and is given charge of the offender, whom he takes by the hand either at his parent's residence or at school, and continually supervises, having power if necessary to bring him again before the judge. The example of Massachusetts in due course influenced other countries, and especially the British colony of South Australia, where a State children's department was created at Adelaide in 1895, and three years later a juvenile court

was opened there for the trial of persons under 18 and was conducted with great success, though the system of probation officers was not introduced.

The movement when once fully appreciated went ahead very rapidly and most civilized countries throughout the world have now adopted it. France, Germany, Spain, Holland, Belgium, Austria, Hungary, Sweden and Switzerland have all established these courts. In Paris the splendid work of M. Henri Rollet secured the foundation of such a court in 1912, while the Berlin children's court, established in 1923, is a particularly well worked and efficient one. Italy, Czechoslovakia, Yugoslavia, Poland, Bulgaria and Esthonia are making arrangements not yet completed. Norway, Denmark and Finland deal with children's cases under a special code, while the Soviet Government of Russia entrusts the whole matter to the education authorities. In India, Madras secured a Children Act under which the powers conferred were to be exercised "only by a juvenile court." Bengal followed in 1922, and the Indian Government are now striving zealously to establish the principle throughout India. Australia, Canada, South Africa and New Zealand all have children's courts in good working order, and in Melbourne, Sydney, Cape Town and Johannesburg they are particularly flourishing. Japan introduced a very interesting system for dealing with offenders under the age of 18 in juvenile courts in the year 1922, Brazil in 1923 and the Argentine in 1924. Amsterdam has tried the new experiment of instituting a police service especially for children, many of its members being women. The republic of Colombia insists that all juvenile offenders shall be examined by a medical man who is present in court as an assessor.

In England the Home Office recommended London police magistrates to keep children's cases separate from those of adults; the same practice or something analogous obtained in many county boroughs, such as Bath, Birmingham, Bristol, Bolton, Bradford, Hull, Manchester, Walsall, Halifax and others, and the Children Act, 1908, definitely established children's courts. This act enacted that courts of summary jurisdiction when hearing charges, etc., against children or young persons should, unless the child or young person is charged jointly with an adult, sit in a different building or room from that in which the ordinary sittings of the court are held, or, on different days or at different times. Furthermore, provision must be made for preventing persons apparently under the age of 16 years whilst being conveyed to or from court, or whilst waiting before or after their attendance in court, from associating with adults, unless such adults are charged jointly with them. The act prohibits any persons other than members and officers of the court, the parties to the case, their solicitors, counsel and other persons directly concerned in the case, from being present in a juvenile court, except by leave of the court. Bona-fide press representatives are also excepted. The main object of the whole system is to keep the child, the embryonic offender who has probably erred from ignorance or the pressure of circumstances or misfortune, altogether free from the taint or contagion that attaches to criminal proceedings. The moral atmosphere of a legal tribunal is injurious to the youthful mind, and children who appear before a bench, whether as accused or as witness, gain a contemptuous familiarity with legal processes.

The most beneficial action of the children's court comes from its association with the system of personal guardianship and close supervision exercised by the probation officers, official and voluntary. Where the intervention of the newly constituted tribunal can not only save the child from evil association when first arrested, but can rescue him without condemnation and commitment to prison, its functions may be relied upon to diminish crime by cutting it off at the source. Much depends upon the quality and temperament of the presiding authority. Where a judge with special aptitude can be appointed, firm, sympathetic, tactful and able to gain the confidence of those brought before him, he may do great good by dealing with each individual and not merely with his offence, realizing that the court does not exist to condemn but to strengthen and give a fresh chance. Where the children's court is only a branch of the existing jurisdiction worked by the regular magistrate or judge fulfilling his

ordinary functions and not specially chosen, the beneficial results are not so noticeable. The Juvenile Courts (Metropolis) Act, 1920, has given legislative authority to this principle by enacting that the home secretary in selecting as presidents of such courts certain metropolitan magistrates "shall have regard to their previous experience and their special qualifications for dealing with cases of juvenile offenders."

In view of the fact that about 50% of regular criminals begin a life of crime when under 21 years of age, the importance of the juvenile courts can hardly be exaggerated. Rightly, sympathetically and firmly dealt with whilst still young, the vast majority of these potential criminals would become good citizens of the State. Bad surroundings, evil companions, undesirable parents, mental and physical deficiencies and various psychological causes are responsible for most juvenile delinquency. The responsibility for discovering, removing or eliminating these causes rests with the children's courts, and too much care, time and effort cannot be expended in the carrying out of this work. The younger the offender, the greater is the need for efficient diagnosis of the underlying causes of his wrongdoing. That the Home Office is fully alive to this necessity is shown by the very careful report of the juvenile offenders committee published in 1927. Valuable as probation has proved itself to be in the adult courts, it is of even greater value in the children's courts. The legislature, recognizing this importance in all courts, has greatly strengthened the system by the passing of the Criminal Justice Act, 1925, the first ten sections of which deal exclusively with the question of probation. It enacts that "one or more probation officers shall be appointed for every probation area," but in country districts combined areas may be created. The secretary of State is empowered to make rules (which have now been promulgated and are in force) governing the appointment, qualifications and salaries of probation officers and the constitution, procedure, powers and duties of the probation committees. UNITED STATES

Legal and Historical Background.—The juvenile court as a distinct organization originated in America but takes its root in legal and philosophical assumptions current in the 19th century. Its immediate aim was to preserve children from the abuses of criminal procedure. Its principles involve a revolutionary change of attitude. The 17th and 18th centuries record great severities. A child of ten who confessed to killing his bed-fellow was punished with the death penalty, because "sparing of this boy simply on account of his tender years might be of dangerous consequences to the public by propagating a notion that children might commit such atrocious crimes with impunity." "In 1828 in New Jersey, a boy of 13 was hanged for murder committed when he was 12. A survey in Illinois revealed that in 1898 575 children between 10 and 16, were confined in the Chicago jail, and 1,983 boys were committed to city prison." Similar conditions existed in every part of the United States.

At first there was no thought of modifying court procedure. The idea was stressed that after conviction the confinement should be apart from adult criminals. Rise of children's reformatories made this possible in New York (1825), Pennsylvania (1828), and Massachusetts (1847). There was also some provision for separate hearings for children, and for probation in Massachusetts between 1870 and 1880, and in New York in 1892. In 1899 the first juvenile court was organized (Cook county, Chicago, Ill.). It brought under one jurisdiction children who violated laws and dependent children, provided identical procedure for both, established probation, decreed that adjudication be deemed not a conviction of crime, but the placing of the child in the relation of ward to the State. The care for the delinquent child was to "approximate as nearly as may be that which should have been given by the parents." Instead of warrant of arrest, examination by a police judge, bail, indictment, jury trial and sentence, there was substituted complaint, investigation by probation officer, petition, informal hearing and commitment. Fines, imprisonment and penal treatment were abolished. The movement spread with rapidity. By

1904 ten States had juvenile courts; after the first ten years, 20 States and the District of Columbia; by 1914, 30 States; and in 1928 only two States (Wyoming and Maine) were without juvenile courts.

This rapid expansion, without trained personnel, led to a period of critical inquiry. The State supreme courts, however, have upheld the constitutionality of the original statutes. Juvenile court ideals have not been applied throughout the rural districts and small towns. In 1918 the Children's Bureau, Washington, D.C., estimated that of 175,000 cases of children in the U.S. courts, approximately only 50,000 went before courts adapted to handle them.

The juvenile court principle is, first, that the child is not an ungrown adult, but a distinct being, physically, mentally, emotionally and socially; the child's response to life is different; secondly, that the State should not proceed against the child as prosecutor, but exercise the chancery power of *parens patriae* to protect the child.

Age-limits.—The legal meaning of the term "child" is defined by statute, which limits the age of criminal responsibility. Under the English common law, no child under seven was held responsible for crime. Belgium in recent years has raised this to 16, the period *sans discernment*. In the United States the tendency is to increase it to 18 and even 21 (excepting offences punishable by death or life-imprisonment). In approximately one-third of the States jurisdiction of the juvenile court extends to children under 16, in one-third to children under 17, and in the remaining third to children under 18 and above.

It is argued that the older child is entitled to trial by jury, and will not be injured by penal treatment. There is however scientific evidence that the child is not capable of complete integration, or maturation, until 21 or beyond, a belief crystallized in the practice of civilized countries to keep him under legal disabilities as regards contract, voting and marriage until age of majority is reached. In the opinion of many experts it is only a question of time until the juvenile court age-limit will be the same as the recognized age of majority.

Treatment.—The psychological importance of the first offence cannot be overstated. Police methods of apprehension and investigation should be eliminated. The child's court hearing in the better sort of American courts is informal. A well trained juvenile court judge does not proceed to disposal unaided. He seeks the wisdom of the clinic and the social worker. If the child has constructive possibilities he may safely be placed on probation.

Foster homes are used in some parts of America for the placement of delinquent children from unfit homes. Maintenance is supplied by public or private agencies. Correctional institutions are used for cases where an extended period of training is indicated, or where the child is under physical or mental handicaps. Some correctional institutions have supplied individual education, notably for girls, in Sauk Center, Minn., Sleighton Farms, Penn., Samarcand, N.C., Gainesville, Texas, and for boys, in New Jersey, California and elsewhere. In these training schools self-government and expert scientific guidance have met with success. Other social resources are clubs for boys and girls in industry, habit clinics, child guidance clinics, religious agencies, Big Brothers or Big Sisters, and Juvenile Protective agencies. These work most effectively under a co-ordinated philosophy of child care. To achieve this a conference is often held for social diagnosis.

Thus the old sentiments of revenge and deterrence give way to a concerted effort to understand, and to remove underlying causes. In this way sponsors of children's courts have become leaders in the scientific and humanitarian movement to prevent delinquency and to increase human happiness.

CHILDREN'S DIET. At the end of the first year the infant has passed from an entirely, or almost entirely, liquid diet to one which includes solid food, and yet not to the same degree nor of the same sort as is given to older children. During the second year, and often during part of the third year, an important factor in determining diet is the progress of dentition; foods which require thorough mastication are clearly unsuitable before the molars are present. On the other hand, it is good that the child should be trained to masticate as early as possible, so that even before the molars are present, solids which crumble easily, e.g., rusks, biscuits and stale bread are good. At the end of the first year the child should have reached a régime of three meals daily, with a drink of milk in the middle of the morning.

Up to the age of three years milk continues to be the most important item in the diet: 1½ pints, exclusive of puddings, should be taken daily. Eggs are also of great value, but must be introduced cautiously into the menu, as some children show an idiosyncrasy to eggs, which produce in them various untoward symptoms. Milk and eggs are rich in the bone-forming lime salts; they are also rich in the growth-promoting and antirachitic vitamins. Another food which is of importance and is, fortunately, a favourite with most children, is potato, which, cooked though it is, supplies very richly the antiscorbutic vitamin; potatoes should be baked in their skins and given thoroughly mashed.

Bread.—At a year old, bread may also form part of the diet, whether as milksop, or bread with butter. For children from one to three years of age it is better to use white bread; older children may have brown occasionally; the amount of indigestible residue from brown bread acts as an intestinal irritant, and young children are specially susceptible to the irritation of undigested material in the bowel, very easily contracting therefrom a mild mucous catarrh of the bowel, which interferes with absorption. Children are almost always fond of biscuits, and these supply carbohydrate (starch and sugar) in a very easily assimilable form, especially if the biscuit is of a variety which crumbles easily and finely under pressure. Hard biscuits have been recommended as encouraging mastication; the finely crumbling biscuits have been thought harmful, as they cling about the teeth; a tooth-brush, however, can remove this objection.

Sugar.—Sugar is needed by children. The starch which is taken in bread, potatoes, and many other foods has to be converted into sugar in the body, and sugar, given as such, is a ready source of energy; childhood, with its ceaseless activity, needs a large supply of energy. On the other hand, excess of sugar results in unhealthy fermentative processes. Nature has included sugar in milk, so that very little should be added to foods made with milk. There is also natural sugar in ripe fruits, but cooked fruit, which is usually not fully ripe, should have sugar added to it. There is no objection to the addition of a little sugar to bread-and-milk, or to porridge, or sprinkled on bread-and-butter. Treacle also, and jam or honey are valuable. The eating of sweets between meals is bad: it tends to destroy the appetite for meals. The best time to give them, if at all, is just after a meal, and those made with plain sugar are less upsetting to the digestion than chocolate.

Fruit.—The juice of raw fruit is a pleasant addition to the diet, and is necessary if the child is not having potato; but for any child who is having an ordinary allowance of potato daily, fruit juice is unnecessary so far as vitamins are concerned. Fruit has, however, other values, in its fruit-sugar and salts, and, moreover, is sometimes useful for its laxative effect. The solid part of raw fruit is not suitable until the child begins to masticate well; fruit such as an apple requires very thorough mastication. Bananas are often given to children at 18 months, or even earlier, but even mashed they are not easy of digestion. Most children are fond of them, and if the digestion will stand it, a mashed banana may be allowed occasionally at 18 months. The real value of apples and pears and many other fruits lies in the mineral salts which are combined with citric, tartaric and malic acids and, being converted into alkaline salts in the body, furnish alkali to

the blood. Grapes are often given in the second year. They supply sugar and mineral salts and, like oranges, provide antiscorbutic vitamin. The skin and pips should be removed; even the substance of the grape itself sometimes causes trouble and can be seen almost unaltered in the stool.

Meat.—The age when meat may be given depends largely upon the stage reached in dentition; finely minced meat is often given to children at 15 months, but the finest mincing is not a substitute for chewing, and it is wiser to wait until all the teeth are present. Red gravy from lightly cooked meat, especially beef, will supply all that the child needs from the meat, and two or three tablespoonfuls of red gravy with potato will make a suitable first course for dinner. Steamed fish, such as sole or plaice, which breaks up into shreds with slight pressure, or chicken pounded into a cream, or brains mashed, may be given when the child has at least 12 teeth.

Soups or broths are often given in the second year as part of the midday meal. For occasional use this is not objectionable, but the nutritive value of any soup or beef-tea is extremely small; if potatoes, peas or barley are included, the value of the broth is chiefly the value of these. Some have advised that in the preparation of broths, broken up bones should be added, perhaps with a small amount of vinegar to help in dissolving out the lime-salts. These salts, however, are much better supplied in milk and eggs, and in general, broths or soups give very little nutrition in proportion to their bulk, which distends the stomach and often prevents the taking of more valuable food.

Vegetables.—Green vegetables are valuable chiefly as supplying mineral salts, especially of potash; they also tend to prevent constipation. Much of their value is lost by the ordinary method of boiling; steaming is preferable, as less of the salts are lost thereby. Spinach has the further value that it contains some iron, which may be of use in blood-making. Carrot is highly indigestible, and has no special virtue apart from being rich in sugar, and is best avoided. Turnips are much less indigestible if well mashed, but of very little nutritive value. Watercress and raw lettuce have very small value as food, and as purveyors of vitamin they are superfluous in any ordinary diet.

All the farinaceous milk puddings, junket and custard, are valuable at any age from a year onwards. For children of two years and more, light suet or bread-and-butter puddings are excellent.

From Three to Five Years.—Much of what has been already said applies equally to children of three to five years. From the completion of dentition to the age of five, the dietary may include, in addition, bacon—fried or cold boiled—bread fried in bacon fat, any fish except salmon and mackerel.

For breakfast, dry cereal preparations, already cooked, are now much in use; they require an amount of mastication which few children will give, and should not be allowed to replace the much more valuable egg, bacon or fish; porridge or bread-and-milk are much better than these dried cereals. Meat and chicken can be given without mincing or pounding: indeed, the child should learn to masticate them. There is no objection to cakes, if not too rich—sultanas are better than currants, and a plain madeira or a ginger cake is best. Milk is the best drink, and the total amount daily should be 1-1½ pints, exclusive of any used in making puddings, etc. At dinner, water should be given, and the child should be allowed water between meals. Cocoa, ovaltine, or very weak China tea may also be allowed.

The diet of a child should be as varied as possible, and this for two reasons: First, that a proper balance of the essential constituents of food may be maintained, and secondly, to prevent monotony, which is bad both for appetite and digestion. A diet well-balanced in the proportions of the various constituents is essential to good health.

(G. F. S.)

CHILDREN'S GAMES. The study of traditional games has in recent years become an important branch of folklore research, and has contributed not a little towards elucidating many unrecorded facts in early history. These games may be broadly divided into two kinds—dramatic games, and games of skill and chance. These differ materially in their object. Games of skill and chance are played for the purpose of winning property from a less fortunate player. The dramatic games consist of non-singing and singing games; they are divided between boys' games and girls' games. Boys' games are mostly of a contest character, girls' of a more domestic type. The boys' dramatic games have preserved some interesting beliefs and customs, but the tendency in these games, such as "prisoner's base," has been to drop the words and tune and to preserve only that part (action) which tends best for exercise and use in school playgrounds. The girls' singing-games have not developed on these lines, and have therefore not lost so much of their early characteristics. The singing games consist of words, tune and action. The words, in verse, express ideas contained in customs not now in vogue, and they may be traced back to events taking place between men and women and between people of different villages. The tunes are simple, and the same tune is frequently used for different games. The actions are illustrative of the ideas to be expressed. The players represent various objects—animals, villages and people. The singing game is therefore not a game in the usual sense of the word. There is no element of "gambling" or playing "to win" in it—no one is richer or poorer for it; it also requires a number of children to play together. It is really a "play," and has survived because it has handed down some instances of custom and belief which were deeply rooted and which made a strong appeal to the imagination of our ancestors. The singing games represent in dramatic form the survival of those ceremonial dances common to people in early stages of development. These dances celebrated events which served to bind the people together and to give them a common interest in matters affecting their welfare. They were dramatic in character, singing, dancing and action forming a part of them, and their performers were connected by ties of place or kindred. They are probably survivals of what we might call folk drama. In those times it was held imperative to perform religious ceremonies periodically; at sowing and harvesting to ensure good crops; in the care of cattle and on occasions of marriage, birth and death. These were matters affecting the welfare of the whole community. Events were celebrated with dance, song and feasting, and no event was too trivial to be unconnected with some belief which rendered ceremony necessary.

At first these ceremonial dances had deep religious feeling for their basis, but in process of time they became purely secular and were performed at certain seasons only, because it was the custom to do so. They then became recognized as beautiful or pleasing things in the life of the people, and so continued, altering somewhat in ideas but retaining their old dramatic forms. They were danced by old and young at festivals and holidays, these being held about the same time of year as that at which the previous religious ceremonies had been held.

Singing games are danced principally in one of two methods, "line" and "circle." These represent two of the early forms of dramatic action. The "line" form (two lines of players standing opposite each other having a space of ground between them, advancing and retiring in turn) represents two different and opposing parties engaged in a struggle or contest. This method is used in all cases where contest is involved. The "circle" form, on the other hand, where all players join hands, represents those occa-

sions when all the people of one place were engaged in celebrating events in which all were interested. Thus games celebrating sowing and harvest, and those associated with love and marriage, are played in this form. Both these methods allow of development. The circle varies from examples where all perform the same actions and say the same words to that where two or more players have principal parts, the others only singing or acting in dumb show, to examples where the singing has disappeared. The form or method of play and the actions constitute the oldest remaining parts of the game (the words being subject to alterations and loss through ignorance of their meaning), and it is to this form or method, the actions and the accompaniment of song and dance, that they owe their survival, appealing as they do to the strong dramatic instinct of children and of uncultured folk.

It will be convenient to give a few instances of the best-known singing games. In "line" form, a fighting game is "We are the Rovers." The words tell us of two opposing parties fighting for their land; both sides alternately deride one another and end by fighting until one side is victorious. Two other "line" games, "Nuts in May" and "Here come three dukes a-riding," are also games of contest, but not for territory. These show an early custom of obtaining wives. They represent marriage by capture, and are played in "line" form because of the element of contest contained in the custom. Another form, the "arch," is also used to indicate contest.

Circle games, on the contrary, show such customs as harvest and marriage, with love and courting, and a ceremony and sanction by assembled friends. "Oats and beans and barley" and "Sally Water" are typical of this form. The large majority of circle games deal with love or marriage and domestic life. The customs surviving in these games deal with tribal life and take us back to "foundation sacrifice," "well worship," "sacredness of fire," besides marriage and funeral customs.

AMERICAN GAMES

Games played by American children fall into two classes, the formal and the informal game. The formal game is given to the children "ready-made," and they play it as someone else has planned it with certain definite form, rules, regulations or words and music. The traditional games discussed above fall into the class of formal games and are used to some extent in American schools and playgrounds, or wherever large groups of children are playing games under direction. The United States is cosmopolitan and the traditional games played are therefore not from any one country. Educators and physical training directors have selected the best of these games and we find in use games from England such as "London Bridge" as well as games from many other countries. These games, however, have lost their traditional significance and the American children play them merely for pleasure in the activity. While there are some formal games such as baseball which are typically American there are no traditional games which reflect the customs and history of the country as do the games of England, France and Germany.

This does not mean that the play life of American children is limited or that there is no play which reflects the national spirit. A study of the spontaneous play of American children has shown that in their unsupervised play they show less interest in formal, traditional games than they do in their own informally organized games. An informally organized game is one in which the organization is developed by the players themselves as the need for it arises. The rules are made by the children and changed to fit the

situation. An illustration of a game of this type may clarify this definition: Several children are playing with a ball, throwing it to each other, running after it, bouncing it. A low wall near by suggests a game. One child says, "Now all stand on the wall and I'll throw the ball to you." As the game progresses the organization grows. One child suggests bouncing the ball, which they do for a time, but it does not seem to work. So they return to the original plan of throwing it. A child happens to miss the ball and there must be a decision as to what is to be done in this situation. The children decide that anyone who misses the ball must get off the wall.

There are endless possibilities in a game of this kind and the children will add to it and vary it according to their age, interests, experience and organizing ability. In this way they learn to direct themselves and others, to keep self-made rules and to meet and think through situations as they arise. Educators and those who have made a study of children's games realize that this development of a game is more valuable than always following the directions and organization of an adult or being bound by rules and regulations made by someone else in another situation. The games children play in America are being influenced by the careful studies that have been made of unsupervised play, and more and more in schools and playgrounds children are being given opportunity to play their own informal games.

Games, whether formal or informal, grow out of certain definite interests and may be classified accordingly:—

Games of Physical Activity.—An interest in games involving physical activity persists through life and there is a different form of game for each stage of development. Very little children make a game of climbing up steps and down again, jumping from a wall, running from one tree to another and so forth. Interest in this simple form of activity persists until the age of five or six years. A little later on this activity may be organized into a simple game of tag, or a race game with definite rules. As the children grow older and develop more skill the element of competition enters in, and with older children most of the games of physical activity involve competition and have quite a high degree of organization. They tend to use the more formal games that have been worked out by adults or other groups of children. We find them playing "prisoner's base," football, basketball and baseball. The older children, however, still show great ingenuity in making their own games and adaptations of games.

Some of the most popular of the traditional singing games are "Ring-around-a-rosy," "Looby Loo," "London Bridge," "Oats, Peas, Beans and Barley Grow," "Farmer in the Dell" and "Drop the Handkerchief."

Hiding and Finding Games.—Interest in this type of game also persists through life with a different form for each stage of development from the "peek-a-boo" interest of the baby to the adult interest in cross-word puzzles (an intellectual form of hiding and finding). The hiding and finding game of the very young child is purely a guessing game, "Which hand is it in?" "Button, button who has the button?" Later children begin to use their senses to help in the finding and we have games in which a child uses his eyes or ears to help him find a hidden object or child. There are many ways of working out this kind of game. "Hide the Thimble," "I Spy" and "Hide and Seek" are typical forms. Here again we find that while older children tend to use an established form they make their own adaptations. For example, the signals in the game "Run Sheep Run" (*Games for the Playground, Home, School and Gymnasium*, by J. H. Bancroft) varied according to locality and were determined by the environment and experience of the children. In a Minnesota town the signals were colours, in the city environment of New York the signals had become pickles, tomatoes and other articles strongly suggestive of a delicatessen store.

There is another way in which this hiding and finding interest manifests itself. This is in the playing of a more intellectual type of game such as "I am thinking of something red," "I am thinking of something that grows on a farm" and so forth. The children show great ingenuity in developing these games and in making them more and more difficult. Finally we find them evol-

ing games which require a knowledge of history, as guessing a historical character by the initials of the character's name; or a knowledge of science, geography and other studies.

Dramatic Games.—Here again the interest persists through life. It begins when the little child plays he is a train or a bear, and later becomes an interest in charades or amateur theatricals. The varied American life particularly lends itself to reflection in dramatic play and in this play are mirrored all the country's local interests, customs, institutions and industries. This type of play is even portrayed in American literature. Louisa Alcott has recorded much typical dramatic play in her stories and other descriptions are found in books by Mary Wells, Eliza Orne White and others.

Little children the world over have certain experiences in common such as eating, sleeping, doctors and sick children. These interests are reflected in the dramatic play of all young children. As their experience is widened their play becomes more varied and we find them playing circus, train and so forth. Literature adds to this experience, and fairies, dragons, kings and queens enter into the play. As the children grow older their dramatic play takes more definite form and has a beginning, a climax, an end. Finally we have a play, made by the children, which calls for costumes, a stage and an audience.

CHILDRESS, a city in the "panhandle" of Texas, U.S.A., near the Red river and the Oklahoma border; the county seat of Childress county. It is on Federal highway 370, is served by the Colorado and Southern railway, and has an airport. In 1900 the population was 692; in 1920, 5,003 (98% native white); and in 1930 was 7,163 by the Federal census. Cattle, hogs, and cotton are raised in the vicinity, and petroleum, natural gas, gypsum, and gypsites are found. The city has cotton compresses and gins and a cottonseed-oil mill, railroad repair shops and an icing station for fruit cars. It was settled about 1888, and incorporated in 1892.

CHILDS, GEORGE WILLIAM (1829-1894), American publisher, was born in Baltimore (Md.), on May 12, 1829. In 1847 he established a book-shop in Philadelphia, and two years later organized the publishing house of Childs and Peterson. In 1864, with Anthony J. Drexel, he purchased the *Public Ledger*. He died at Philadelphia, Feb. 3, 1894. Childs was known for his public spirit and philanthropy. He erected memorial windows to William Cowper and George Herbert in Westminster Abbey (1877), and to Milton in St. Margaret's, Westminster (1888), a monument to Leigh Hunt at Kensal Green, to Shakespeare a memorial fountain at Stratford-on-Avon (1887), and monuments to Edgar Allan Poe and to Richard A. Proctor. He gave Woodland Cemetery to the Typographical Society of Philadelphia for a printers' burial-ground, and with Anthony J. Drexel founded in 1892 a home for union printers at Colorado Springs, Colorado.

His *Recollections* were published in Philadelphia in 1890.

CHILD STUDY ASSOCIATIONS are of two types, those whose programmes are devoted to child study in general and those who have incorporated in their programmes a department of special work. In the United States the associations either organize or encourage the organization of study groups, and undertake research, lectures, conferences, consultation service, training of leaders for study groups, service to schools and colleges and the publication of books and pamphlets.

In England, the British Child Study Association (founded 1894), the Childhood Society and the Parents' National Educational Union are the most outstanding associations. In the United States, The Child Study Association, National Congress of Parents and Teachers, American Association of University Women, American Home Economics Association, Progressive Education Association and the Parents' Publishing Association which publishes *Children, the Magazine for Parents*, are all doing significant work. The New Education Fellowship in several countries in Europe has a programme similar to that of the Progressive Education Association.

CHILD WELFARE AND CHILD LABOUR. Systematic child welfare work, the object of which is to promote the mental, moral and physical well-being of children, is a comparatively modern development and it received little official recognition in any country before the middle of the 19th century. At first, the work was developed on local national lines. Later, under progressive influences, the work became of common interest to different countries and a subject of mutual co-operation. Finally, child welfare has been definitely accepted as a subject of international concern and interest, and this aspect has been further emphasized by the inclusion of international child welfare work among the social and humanitarian activities of the League of Nations.

I. CHILD WELFARE

In all civilized countries there will be found legislation directed towards securing care and protection for children. Side by side with these official provisions, there will be found work carried on by voluntary and charitable organizations which supplements, and has even in many cases initiated, official child welfare measures. An outline of the English system gives the chief features of the work and a general indication of the lines on which, subject to local differences of outlook and of organization, each country covers the field of child welfare.

Welfare of Children of School Age.—Under various British Education Acts, and notably the Act of 1918, provision is made for the primary, secondary, technical and higher education of school children. The Board of Education administers the Acts through the Local Education Authorities. Special provisions are made for the education and care of physically and mentally defective children, for the feeding of necessitous cases, and for school medical inspection and treatment. The Board of Education has power to give grants to voluntary societies organizing supplementary work, such as play centres, continuation classes and educational club work.

Neglected or Necessitous Children.—Under the Poor Law Act 1889, as amended by the Act of 1899, Boards of Guardians have powers enabling them to adopt neglected children. Such children may also be dealt with by Juvenile Courts under the Children Act 1908. The reorganization of the Poor Law, under consideration in 1926, contemplates the transfer of the powers of boards of guardians to the local authorities.

Progressive movements in child welfare work tend to spread beyond the country of their origin. The main reasons for this extended influence are that child welfare is an interest common to every country, that much of the work is carried on by organizations which are international, and, lastly, that the co-operation of one country with another is necessary for solving certain child welfare problems.

The Influence of National Schemes.—New experiments in other countries often lead directly to the local development of national schemes. Thus, the *Consultation des Nourrissons*, started in Nancy in 1890, and the *Gouttes de Lait*, instituted a few years later in France, attracted widespread attention, and were largely instrumental in inspiring other countries, including England, to develop infant welfare work. Codifying and consolidation of national child welfare legislation, as exemplified in the English Children Act 1908 the Belgian *Loi sur la Protection de L'Enfance* 1912, and in the Children's Codes of the United States of America, have also influenced the legislation in other countries. The Federal Children's Bureau, established in Washington in 1912, is another interesting national scheme, consisting of a special department of State established to deal with child welfare.

Influence of Voluntary Societies.—Voluntary societies, engaged either on general or on some specialized child welfare work, are often international, and so form another channel through which progressive ideas pass from country to country. These associations, from their central office, guide and develop the policy of their many branches throughout the world, and can thus introduce enlightened methods from one country into their institutions in another. Official international child welfare work will be shown later to derive its source from the formation of international

child welfare organizations and from their congresses. Even where international associations are not primarily concerned with children, it is common to find at their congresses, whether on penology, on industry, on hygiene, or whatever the subject may be, resolutions which encourage international co-operation in some branch of child welfare.

Agreements Between Different Countries.—Lastly, where there are problems affecting the mutual interests of two or more countries a national solution is insufficient, and must be replaced by agreements for reciprocal action. As regards child welfare such problems arise chiefly in questions of relief, of repatriation, and of emigration. Reciprocal agreements for relief often contain clauses to include the relief of children. France has recently concluded a series of "assistance" agreements with other countries, *i.e.*, with Italy (1919), Poland (1920), Belgium (1921), and with Luxembourg (1923). Belgium and Luxembourg exchanged a "Declaration" on similar lines in 1923. General repatriation agreements concluded between States cover also cases in which children are to be repatriated. There are two agreements which relate only to minors, *i.e.*, between Belgium and Holland in 1913, and between Belgium and France in 1925. Where these two agreements apply, a minor can be repatriated to his home country, but it must be judicially proved that this is done in his own interests.

A few agreements on emigration and kindred subjects contain clauses relative to young people. There is, for instance, an arrangement between France and Italy, dated June 15, 1910, regulating the formalities which govern young workers of the one country emigrating to work in the territory of the other. Child migration from Great Britain to her colonies is subject to regulations made on either side, but not usually to joint agreements. An exception to this arrangement is the agreement of April 11, 1923, between Canada and Great Britain concerning a grant towards the cost of emigrating children. The First Hague Convention 1902 relates to the guardianship and protection of the person and of the interests of minors in a foreign country. This Convention has been ratified by Germany, Belgium, Spain, Hungary, Italy, Luxembourg, Netherlands, Norway, Portugal, Rumania, Sweden and Switzerland.

INTERNATIONAL CHILD WELFARE

It is convenient to consider international child welfare work under three divisions. Firstly, there is the history of its development, which includes Children's Charters; secondly, there is the organization and scope of the work under the League of Nations; and, thirdly, there is the specialized subject of the regulation of child labour, which falls within the province of the International Labour Office.

Development of International Child Welfare.—Several international congresses were held in Belgium between 1890 and 1911, which were known as Congrès des Patronages. These "Patronages" were semi-official associations which dealt primarily with the after-care of prisoners; but, so far as child welfare was concerned, they early began to interest themselves in the particular type of child who was in moral danger or who was delinquent. Switzerland, in 1911, was the first country to plan the institution of a central office to deal with all branches of child welfare on an international basis. The Belgian Government also interested itself in the matter and organized the First International Congress for the Promotion of Child Welfare at Brussels in 1913. The Congress resolved to found an international child welfare association, but the outbreak of war in 1914 prevented any immediate realization of this project.

The second International Congress for the Promotion of Child Welfare was held in Brussels in 1921, and resulting from this Congress the International Association for the Promotion of Child Welfare was founded in Brussels. It was established to facilitate study by centralizing all information on child welfare work, to assist co-operation between one country and another, and generally to further and encourage international interest and progress. The new office did not, however, obtain the full measure of support that had been anticipated, since some countries desired, as a matter of principle, to see its work carried on by the

League of Nations. This principle was finally accepted, and the Council was asked to recommend to the Assembly that the League of Nations should undertake international child welfare work. The recommendation was made, and was agreed to by the Assembly in 1924. The Association continues its activities as a private organization serving as a link between voluntary child welfare work in different countries.

The famine and privation in many lands after the World War told especially heavily upon the children. Relief was organized by the Save the Children Fund, and branches of the society were established in many countries. Starting at first as a relief organization the Save the Children Fund gradually enlarged its scope to include general child welfare work. The headquarters of the Save the Children Fund (International Union) was established in Geneva in 1920, and under its auspices the First General Child Welfare Congress took place in Geneva in 1925. In America also, a general Child Welfare Association was set up in Montevideo in 1924, as a result of Pan-American Congresses for Child Welfare. It is known as The American International Institute for the Protection of Children.

Children's Charters.—National measures for the protection of children are generally found embodied in a special child welfare law, and this legislation is often popularly described as a Children's Charter. The term has, however, been applied specifically to a new development in the field of child welfare. It seems to have been felt that though in theory child welfare had been accepted as an international responsibility, yet practical results would not follow unless a clear statement was drawn up as to what that responsibility represented. To meet this requirement a Children's Charter was enunciated by the International Council of Women in 1922. This Charter sets forth under headings, and in some detail, the minimum rights which should be accorded to childhood. The form of the Charter is general, but it is intended that each nation shall remodel the Charter for its own use, and make it an exposition of practical child welfare aims capable of being worked out locally. The National Council of Women of Great Britain, in conjunction with the Save the Children Fund, have followed this lead, and issued in 1924 a Children's Charter for Great Britain.

Akin to these Children's Charters is a shorter and more generalized expression of the duty of humanity to childhood known as the Declaration of Geneva. This Declaration, published in May 1923, was drawn up by the Save the Children Fund (International Union) and has been translated into many languages. The League of Nations has recommended the Declaration as a guide to the principles which should inspire child welfare work.

Child Welfare under the League of Nations.—By resolutions of the Fifth Assembly on Sept. 26, 1924, the League of Nations undertook the promotion of international child welfare, and the work of organization was entrusted to the Advisory Commission on Traffic in Women and Children, which is served by the Social Section of the Secretariat. The Advisory Commission reconstituted itself into two Committees, one to deal with traffic in women, and the other to be known as the Child Welfare Committee. The Child Welfare Committee consists of the delegates of certain governments named by the Council, and of special assessors, representing international organizations dealing either with general child welfare, or else with special branches of the work. In addition, a representative from the Health Section of the League, and one from the International Labour Office, serve as liaison officers. The scope of the work falls into three categories:—documentation, or the collection and analysis of national child welfare laws, which includes the administration of these laws; research, or the local investigation of child welfare schemes or problems; and discussion or the consideration by the Child Welfare Committee of the results of the work of documentation and research. A subject of special international importance may be referred for consideration to international conferences, and may form the material for an international convention. The Child Welfare Committee, as reconstituted, held its first annual meeting in March 1926. The subjects submitted included infant welfare, child labour, the legal age of marriage and the age of consent, the repatriation of foreign children, family allowances

and the effects of the cinema. Since that date further subjects such as the study of the protective laws for the illegitimate child, the education for useful citizenship of the blind child and the study of the delinquent child have been added to the programme.

II. CHILD LABOUR

The movement for the legal prohibition or restriction of child labour developed during the industrial revolution when the evil effects of industrial employment on the physical, mental and moral development of children first attracted public attention.

The first legislative measure restricting child labour was adopted in England in 1802. Since that date nearly all the industrial countries of the world have progressively restricted child labour, and in recent years the minimum age below which industrial employment is prohibited has been rapidly raised on an international basis. When in 1890 an international conference met at Berlin it was found impossible to agree on the prohibition of the employment of children under 12 in the countries of southern Europe, but when the first International Labour Conference of the I.L.O. met in Washington in 1919 agreement was reached on a Draft Convention which raised the minimum age of employment in industry to 14. By the beginning of 1928 this Convention had been ratified by 15 countries: Belgium, Bulgaria, Chile, Czechoslovakia, Denmark, Estonia, Great Britain, Greece, Irish Free State, Japan, Latvia, Poland, Rumania, Switzerland and Yugoslavia. As a consequence of the adoption of this Draft Convention a general tendency has developed to incorporate the age of 14 in the provisions of national child labour legislation.

In Great Britain the employment of children is regulated by the Women, Young Persons and Children (Employment) Act of 1920, which provides that no child (*i.e.*, person under the age of 14 years) shall be employed (a) in any industrial undertaking, or (b) on board ship, with certain exceptions. Detailed measures with regard to the employment of children are also embodied in the Education Act 1918 and the Education (Scotland) Act 1918.

In the Dominions the minimum age is also in general 14. In Australia and Canada, where the conditions of employment in industry are governed by State and provincial legislation, while the minimum age is generally fixed at 14 both for boys and girls, in certain Canadian provinces and in Victoria the minimum age for girls is raised to 15. In New Zealand, South Africa and the Irish Free State the general minimum age is 14.

In India the minimum age was raised in 1922 from 9 to 12. The Act of 1922, by which this reform was made, also prohibits night work of persons under 15 and stipulates that no person under 15 shall be employed in any factory for more than 6 hours per day. By an Act of 1923 it is further provided that no child under 13 shall be employed in a mine or be allowed to be present in any part of a mine which is below ground.

In British colonies the minimum age varies in accordance with local conditions of industrial development, climate and other circumstances. Thus, while in Ceylon it has been found possible by an Ordinance of 1923 to provide that no child under 14 shall be employed in any industrial undertaking or on board ship, in Hongkong the Ordinance of 1922 fixes the age at 10 for factory employment and at 12 for carrying coal, building material, or lebrils.

In Europe the legal minimum age for admission to industrial employment varies from 15 to 10. It is 15 in Poland and 14 in Austria, Belgium, Czechoslovakia, Denmark, Estonia, Finland, Greece, Latvia, Netherlands, Norway, Kingdom of the Serbs, Croats and Slovenes, Sweden (girls), and Switzerland. The minimum is 13 in France and Germany and Sweden (boys), 12 in Italy

and 10 in Spain.

In those extra-European countries in which child labour legislation has been adopted, the minimum age falls within the limits indicated for Europe. In many countries, however, in which little or no industrial development has taken place, no legal restrictions on child labour exist.

It should be noted that the ages indicated above are in many cases a general minimum and provision is frequently made in the laws concerned for exceptions. In Czechoslovakia, for instance, while the Act of 1918 stipulates that in industrial undertakings and also in agriculture and forestry children shall not be employed before the conclusion of their compulsory school attendance and before they are 14, the Act of 1919 permits, with certain provisos, the employment of children over 12 and the employment of children on light work in agriculture and domestic occupations as soon as they attain the age of 10.

The minimum ages which have been indicated above are in general those fixed for industrial employment. In certain cases the same age limits are also laid down for employment on board ship and in commerce. The scope of the application of minimum age legislation to industrial undertakings varies widely, as the definition of "factory" or "workshop" is by no means uniform. Minimum age legislation usually does not apply to work-places or ships in which only members of the same family are employed, nor to work done by children in technical schools provided that such work is approved and supervised by public authority. In the case of dangerous or unhealthy work, and night work employment is often forbidden under 18. For work in mines the minimum age is often fixed at 16. Enforcement usually depends on the factory inspectors and in order to facilitate their work it is often provided that every employer of young persons shall keep a register of such workers up to 16 or 18 years showing their date of birth.

The regulation of child labour in agriculture is in general much more elastic than in industry. While it is not open to doubt that it is injurious to children to employ them in industry, in agriculture the need of safeguarding the child is less obvious. The child engaged in agriculture is leading a life in the open air and is in general employed by his own parents. Under these conditions the child's mental and physical development is less likely to be adversely affected by agricultural work than by employment in industry. At the same time it is easy to see that in agriculture also abuses may occur, and many States have regulated the employment of children in agriculture as well as in industry. In general, however, the minimum age fixed for agricultural employment is considerably lower than for industrial employment. In Denmark, for instance, where the minimum age for industry is 14, a child is permitted to work in agriculture with machinery four years earlier. Even where legislation covering agricultural employment exists, it is always difficult to enforce it directly. Most European States seek to safeguard childhood in rural districts through the indirect operation of education laws, which fix a statutory age-limit below which school attendance is compulsory.

The provisions of minimum age legislation are reinforced in actual practice by a variety of other measures. Under the family allowance system, for instance, now widely applied in France, Belgium, and other countries, by which wage-earners in certain industries receive, in addition to the basic wage, allowances for dependent children, an age limit is fixed beyond which children are not considered to be dependent. As this age limit is usually 14, the system has some influence in inducing parents not to put the children to regular employment before this age. The same sort of influence is exercised by social insurance systems. While national systems of workmen's compensation, health insurance, unemployment insurance and other forms of social insurance differ greatly from country to country, the existence of dependent children is generally taken into account in assessing benefits. These provisions therefore tend to protect the children from being sent to work at too early an age.

An increasing tendency is developing internationally to protect children in regard to employment not only negatively but also positively. It is being more and more clearly realized that it is

not enough merely to prohibit the employment of children under 14 and the night work of young persons under 18. It is necessary to prepare the child constructively for the occupation which he will eventually enter. Thus increasing attention is being devoted in many countries to vocational education, technical training and vocational guidance, with a view to equipping the child as completely as possible for the moment when he will launch out on the adventure of industrial employment.

In general it may be added that most labour legislation has some sort of repercussion, however remote, on the welfare of the children. Legislation providing for the establishment of minimum wages, for instance, by preventing the payment of sweated wages, results normally in safeguarding the standard of life of the family as a whole. Similarly, legislation fixing an eight-hour day may be considered to have a real influence on child welfare inasmuch as it permits the normal man to devote more of his time to family life and to the well-being of his children. (G. A. J.)

King, *The Employment and Welfare of Juveniles*, etc. (1925); *Reports of the Children's Branch of the Home Office* (1923, 1924, 1925); League of Nations' publications, *Report of the Advisory Committee on the Traffic in Women and Protection of Children*, Official Jour. (July, 1925); *Report of the Child Welfare Committee* (1926).

Texts of Child Labour Laws are in the *Bulletin of the International Labour Office* (Basle, 1906 and 1919), and in the *Legislative Series* (International Labour Office, Geneva). Information on the application of legislation is contained in the Factory Inspectors' Reports and in official reports issued by Government departments in the various countries.

III. CHILD WELFARE IN THE UNITED STATES

Within recent years, there have developed in the United States a number of institutes of child welfare for the purposes of conducting fundamental and practical research on the development of the child, training future workers in the field and carrying on programmes of educating parents in child care and training. These institutes are usually established as separate divisions in universities, with provision for the co-ordination of the work of a number of departments interested in children, such as anatomy, pediatrics, psychology, home economics, education, etc., so that research, instruction and parental education may be more effectively conducted.

In function, such organizations are to be differentiated from clinics and children's hospitals in that they are concerned much more with the development of typical or normal children than with the treatment of ill, handicapped or diseased children. They differ, also, from child guidance clinics in that they emphasize the research and educational function rather than the consultation and clinical function. Nor are the institutes to be looked upon as charitable or philanthropic organizations, since they are not concerned so much with alleviation as with prevention. Emphasis throughout is placed upon the scientific approach and a long time-view of the child problems. The institutes as organized emphasize what has come to be called the "whole child," that is, the physical, mental, educational and social welfare of the child as a unit, rather than one aspect of the child's life. This is accomplished by providing opportunities for co-operation between specialists from different scientific fields.

Historically, the institutes made their first approach in the pre-school field by virtue of the fact that study of early development is fundamental to studies of later development, that knowledge of the young child is less complete in many respects than knowledge of the school child and adolescent, and because the best period for training parents with respect to the care and training of children seems to be the period when there are young children at home. There is, however, no necessary identification between the work of the institutes and the pre-school field, since the organizations developed are carrying on studies at all ages. Some of them are emphasizing the so-called longitudinal studies, that is, studies beginning with the young child and following the development of these children in detail through subsequent years

Various devices have been developed for securing children for study. Of these, the most common is the nursery school for children between the ages of two and five. Institute nursery schools are experimental schools rather than schools for the children of working mothers or play schools. In some instances, an attempt is made to secure a cross-section of the children in the community rather than a selection from a particular social or economic class. In order to study younger children, some institutes have developed facilities for the 24-hour-a-day care of infants, others have set up investigations of infants in private homes. Through co-operation with experimental schools and with public schools, data are obtained on older children.

The leading institutes are: the Iowa child welfare research station at Iowa City, Ia., founded in 1917; the Institute of child welfare research at Teachers college, Columbia University, New York City, founded in 1924; the Institute of child welfare at the University of Minnesota, Minneapolis, Minn., founded in 1925, and the Institute of child welfare at the University of California, Berkeley, Calif., founded in 1927. Organizations doing similar work are: the Merrill-Palmer school of home-making at Detroit, Mich., and the St. George's school for child study at Toronto, Canada. (J. E. A.)

IV. CHILD LABOUR IN THE UNITED STATES

The U.S. Census of 1920 reports over one million (1,060,858) children 10 to 15 years of age, inclusive, as "engaged in gainful occupations" in the United States. This number was approximately one-twelfth of the total number (12,502,582) of children of that age in the entire country. The number of child workers 10 to 13 years of age, inclusive, was 378,063. The census does not report the number of working children under ten years of age, but it is known that such children are employed in large numbers in agriculture and in smaller numbers in other occupations.

Of the child workers 10 to 15 years of age, inclusive, in 1920 647,309 or 61%, were reported to be employed in agricultural pursuits, the majority (88%) as labourers on the home farm. There were 185,337 children, or 17.5%, employed in manufacturing and mechanical industries. Over 80,000 children were engaged in some type of clerical occupation; approximately 63,000 were in trade; 54,000, the majority of them girls, were working at occupations classified under "domestic and personal service"; and 7,191—almost all of them boys—were employed in the extraction of minerals.

During and since the World War the number of working children fluctuated greatly. The serious industrial depression which followed the outbreak of the war brought a sharp decrease. By the latter part of 1915 the effect of foreign orders for war goods was beginning to make itself felt, and an unprecedented rise in the number of employed children followed. After the United States entered the war, the rising cost of living, the absence of older members of the family on military duty, high wages because of labour shortage, and a restlessness on the part of the children themselves, led many under 16 to leave school for work. Available statistics show that in most places the peak in the employment of children was reached in 1918. The shutting-down of war industries and the return of soldiers resulted in a temporary decline in 1919.

The census of 1920 records a considerable decrease since 1910 in the number of children reported at work. Although the total child population 10 to 15 years of age, inclusive, increased 15.5% the number of working children reported decreased almost half (46.7%). A corresponding decrease took place in the proportion of all children of these ages who were employed in gainful occupations, from 18.4% in 1910 to 8.5% in 1920. The decline is most striking in connection with agricultural pursuits, in which the number of children employed decreased 54.8%. In this connection the Census Bureau points out that the census of 1920 was taken in January while the census of 1910 was taken in April, so that the reduction in agricultural employment is explained in part at least by that fact.

The most important legislation between 1910 and 1920 was the enactment of the first Federal child labour law, which came

into operation in Sept. 1917. This Act prohibited the shipment in interstate or foreign commerce of the product of any mine or quarry in which children under 16 were employed, and the products of any mill, cannery, factory, workshop or manufacturing establishment in which children under 14 were employed or children between 14 and 16 were employed more than eight hours a day, or six days a week, or before 6 A.M. or after 7 P.M. It was attacked as unconstitutional and on June 3, 1918, the U.S. Supreme Court held, by a vote of 5 to 4, that it did not constitute a valid exercise of Congress' constitutional authority to regulate foreign and interstate commerce. A child labour tax clause was then inserted in the Revenue Act of 1918. It placed a 10% tax on the net incomes of establishments employing children of the ages and for the hours specified in the previous Federal law. This was held an unconstitutional exercise of Congress's authority by the Supreme Court in 1922. A proposal for an amendment to the United States Constitution specifically giving to Congress the right to regulate or prohibit the labour of persons under 18 years of age received the requisite two-thirds vote in Congress and was submitted to the States in June 1924. Up to May 1, 1927, five States had ratified the amendment and it had been rejected by both Houses of the Legislatures of 24 States.

In the child-labour legislation enacted by the various states there are many differences. It is usually required:—

- (1) That a child must reach a specified age and an educational and physical standard before he can be industrially employed;
- (2) That an official work permit must certify his ability to meet the standards established by the statute;
- (3) That the age at which children may be employed at night or in hazardous or unhealthful occupations must be higher than the age at which they may be employed in general occupations.

Of these standards the minimum age was the first to be generally adopted. With some exceptions, every State except two (Utah and Wyoming) has prohibited the employment in industry of children under 14 years of age. That the present tendency is toward the establishment of a higher age is indicated by the fact that seven States (California, Maine, Michigan, Montana, Ohio, Rhode Island and Texas), representing all parts of the country, have raised the age above 14 years.

In 44 States child-labour laws prohibit the employment at night of children at least up to 16 years of age in an enumerated list of occupations. The hours vary. For example, New York prohibits the employment of children under 16 years after 5 P.M. or before 8 A.M.; California after 10 P.M. or before 5 A.M. In 31 States, including those of most importance industrially, laws prohibit the employment in certain unhealthful processes of children, usually under 16 years of age, sometimes 18 years of age. (G. AB.)

BIBLIOGRAPHY.—Fourteenth Census of the United States: Population, 1920, Occupations of Children, Reports of the Children's Bureau of the U.S. Department of Labor.

CHILE (possibly from the Quichua *Tchili*, snow) is a South American, west coast republic, occupying the limited western slopes of the continent south of Peru. It is a narrow ribbon-like country, varying from 46 to 250 m. wide, with a meridional length of 2,661 m., and extending approximately between 17° 25' S. and 55° 59' S. It thus has a greater inhabited latitudinal range than any other country in the world. No thorough survey of the entire country has ever been made, but the area is estimated officially at 751,515 Km² (290,085 sq.m.). The country is bounded on the north by Peru, on the east by Bolivia and Argentina, and on the south and west by the Pacific ocean. Topographically, the country is divided into three fairly distinct belts: the Andean on the east, the coast range on the west, and the central or longitudinal valley in the middle. Climatically it is also divided into three zones: the desert region, north of about 30°, where rain rarely falls; the southern rainy belt, south of about 40°, with a precipitation of 100 in. or more, and in places more than twice that amount; and the central zone, between the two in latitude and with a much more favourable rainfall. The country may also be divided geographically into three divisions, roughly corresponding to the climatic zones: the northern mineralized region with its life centered about mining; the central, made up of the justly famed

Vale of Chile, the agricultural centre with its allied industries; and the southern forested part, sparsely populated, with most of the land given over to the Indian.

Physical Features.—The northern coast of Chile conveys the impression of a great land barrier, with a remarkably even skyline, that rises almost vertically out of the sea to a height of 600 to 1,500 feet and rarely up to 6,000 feet. There is no true coastal plain and only at the more sheltered places or where a stream cuts through to the ocean is there sufficient level land for town sites. This coastal bluff materially lengthens the routes into the interior and thus seriously handicaps movement. South of Valparaiso the coastal escarpment is more broken and the elevations assume the characteristics of a mountain chain. From Chiloe south the region subsides leaving only the higher parts of the coastal range above the water as islands. The coast range therefore is not continuous but is an elevated plateau area, presenting a steep escarpment toward the west and gradual slopes to the eastward.

The great barrier ranges of the Andes, which make up fully a third of the country, may be divided roughly into two groups at about 30° south. The southern forms a rather narrow complex chain composed of two parallel ranges of fairly equal altitude and so close together as to permit little development of intermediate valleys and plateaus. In general the chain increases in width toward the north until it reaches a maximum of 100 m. or more. It also increases in height from an altitude of 6,000 to 7,000 ft. at the southern end, until it culminates at about 32° 30' S. in Aconcagua, which is over 23,000 ft. above sea level. This section of the Andes is a less serious barrier than others because the mountain belt is relatively narrow and the passes comparatively low. The highest part of the tunnel on the trans-continental railway from Valparaiso to Buenos Aires is 10,469 ft., and of the nearby Uspallata pass, 12,795 feet. Southward occur still lower passes until at about 40° 30' S. the Nahuel Huapi is only 4,920 feet. From this point onward the passes are low enough to permit trade to alternate between Chilean and Argentine centres. This entire southern section offers little to man and consequently is very sparsely settled. The lack of water in the north makes the working of mines difficult, while the cold and excessive precipitation of the south, coupled with the general ruggedness of the section, renders much of the south unfavourable even to grazing. Yet from Aconcagua to the strait snow domes and glaciers give unexcelled dignity and beauty to the range.

North of 30° the Andes are divided into several chains of which the western forms the major eastern boundary of northern Chile. No important stream cuts this western range, which is higher than the others and has higher passes. Two railways cross it, the one from Arica at 13,956 ft. and the one from Antofagasta at 12,972 feet. The former utilizes 22 m. of cog-rails in its entire length of 281 miles. The extreme ruggedness, the aridity, and the cold of this section limit crop raising and grazing, but it is highly mineralized, although handicapped by the lack of water.

Between the coast range and the Andes lies the so-called longitudinal valley. This is not a true valley but an irregular depression, in places 25 to 50 m. wide and at times reaching an altitude of 3,000 to 4,000 feet. In some sections it is broken by isolated groups of mountains or by spurs from the main range, which divide the portion above 30° S. into a series of basins, locally known as pampas. The most northern of these is the Tamarugal extending north from the river Loa. This differs from the others in that the ground water in places lies within four or five feet of the surface. Although on the whole this pampa is very barren of vegetation there are remnants of what once must have been extensive thornwood areas. The desert of Tarapaca lies in the western part of the Tamarugal pampa and furnishes nearly half of Chile's nitrate. Practically all the rest of the nitrate is produced in the neighbouring province of Antofagasta although a very small amount comes from Atacama still farther south. In this province the desert pampas end with an irregular mass of low mountains which occupy the whole belt between the ranges, until approximately the latitude of Valparaiso. Here begins the Vale of Chile, one of the finest agricultural valleys in the world, which is continued south until approximately 40°. The longitudinal valley

then gives away to a series of lakes, and then to a complex series of beautiful islands sparsely inhabited by Indians. (W. H. Hs.)

Geology.—Along the coast of Chile lies a belt of rocks formed mainly of old granite and schist and overlying Cretaceous and Tertiary deposits; farther inland is the Western Cordillera of the Andes, which is composed chiefly of intrusive masses, volcanic rocks and folded Mesozoic beds. The deposit in the great longitudinal valley of Chile, which lies between these two zones, is formed of debris that is in places more than 300 ft. thick. In northern Chile the rocks of the coastal zone, which disappear northward beneath the Pacific, consist mainly of isolated masses that stand close to the shore or that project into the sea. South of Antofagasta these old rocks, which there begin to rise to higher levels, form a nearly continuous belt along the coast, extending southward to Cape Horn and occupying the greater part of the islands of southern Chile. They are greatly folded and are doubtless Palaeozoic. In northern Chile the Cretaceous and Tertiary beds of the coastal zone are of small extent, but in southern Chile the Mesozoic beds, which are at least in part Cretaceous, form a rather wide band. The Tertiary coastal beds include both marine and terrestrial deposits, and most of them appear to be of Miocene or Pliocene age. The whole of the northern part of Tierra del Fuego consists of plateaus formed of horizontal Tertiary beds. The northern part of the Chilean Andes, which is the Western Cordillera of Bolivia, consists almost entirely of Jurassic and Cretaceous sediments and Tertiary eruptive rocks. The Mesozoic beds are thrown into a series of parallel folds, which run in the direction of the mountain chain. Into these folded beds are intruded granitic and other igneous rocks of Tertiary age, and upon this foundation rise the cones of Tertiary and later volcanoes. Triassic rocks are found only at La Ternana, near Copiapo, where coal seams containing upper Triassic (Rhaetic) plants have been found, but the entire Mesozoic series appear to be represented at different places. The Mesozoic rocks are chiefly marine sandstone and limestone, but they include also tuff and conglomerate of porphyry and porphyrite. These porphyritic rocks, which form a characteristic element of the Southern Andes, are volcanic, and as they contain marine fossils they must have been laid down beneath the sea. They are not confined to any one geologic horizon but occur at different levels in the Jurassic beds and at some places in the Cretaceous. Here and there they may be traced laterally into the more normal marine deposits of the same age. A large part of the Andes is covered by the products of the great volcanoes that still form the highest summits. The volcanic rocks are liparite, dacite, hornblende andesite and pyroxene andesite. The recent lavas of the volcanoes in southern Chile are olivine-bearing hypersthene andesite and basalt.

(G. McL. Wo.)

Ports.—As outlets for her products Chile is unusually rich in ports, but singularly unfortunate in harbours. These, for the most part, are little more than open roadsteads, and the transfer of goods in practically all cases is done by means of lighters. Moreover the heavy swells along the major part of the coast frequently cause the transfer of goods to be abandoned temporarily for hours, or even days. Of the 57 ports listed relatively few are very important in international trade, and due to the abrupt slope of the ocean bottom artificial protection is both costly and difficult. Many breakwaters have been constructed of recent years, however, particularly at Antofagasta and Valparaiso, but without securing thoroughly safe anchorage at those ports. Valparaiso also illustrates the case of an older port which is favoured by the government in its fight for continued supremacy. In colonial times it was selected as the outlet for central Chile because the traffic of that day could pass from the capital to the coast without encountering any considerable ford. Better natural harbours are to be found in the vicinity, both to the north and south of it and Valparaiso today is meeting serious competition from San Antonio, 50 m. below, which ships the large copper output from the Rancagua district and is gaining in general commerce. Valparaiso is also handicapped by the unwise selection of the route for the railroad leading to the interior. Antofagasta, which of late has surpassed Iquique as the chief port for the shipment of nitrates,

now finds itself contending with Tocopilla to retain the exports and imports passing through it to and from the copper centre at Chuquicamata. Arica, the northernmost port, gains its economic importance as an outlet of the Bolivian plateau but plays a more conspicuous part as a prospective diplomatic pawn. This port and its fellows in the north, like Valparaiso, are hampered by railway conditions. Talcahuano in the south is the chief naval station of the country as well as the commercial outlet of an extensive section. Near by, Coronel is one of the three ports serving the coal producing district as Cruz Grande, north of Valparaiso with its direct docking facilities, serves the iron mines of Tofo. Valdivia, through its port, Corral, and Constitución are able to make some commercial use of the rivers on which they are located. Magallanes (Punta Arenas) on the Straits of Magellan gives Chile the distinction of having the most southerly port in the world.

(W. H. Hs.; I. J. C.)

Rivers.—Due to the general outline and topography of the country, the rivers are short and unimportant except for the life giving waters they may bring, and have little or no significance in directing the settlement or trade of the country. In the north they are few, and for a distance of approximately 600 m., the waters of only one, the Loa, reach the sea throughout the year. This stream, the longest in Chile (440 km.), has made possible certain settlements. The Copiapo, 300 km. long, marking approximately the southern limit of the northern desert, once discharged its waters into the sea, but rarely does so now, as the needs for irrigation are greater than the supply. The rivers to the south are better fed at their heads and flow through much less arid regions. Some of them become raging torrents at certain times of the year; a few have recently been harnessed for the production of electricity. The electrification of the road in the Chilean section of the Trans-Continental has already been completed together with the main line to the capital and other minor developments. With the increased demand for electric current has come also the storage of waters for irrigation.

Lakes.—The lakes of Chile have little significance in the life of the people. In the north occur occasional salt playas, which are dry the greater part of the year. In central Chile, south of the Bio-Bio river, there is a series of very picturesque lakes in the provinces of Cautin and Llanquihue. The largest of these lakes are Ranco and Llanquihue, the former with an estimated area of 200 sq.m. the latter 300 square miles. Due to its natural beauty, the lake region gives promise of becoming the resort place for Chileans during the dry season.

Climate.—Not many countries have the climatic extremes of Chile. The north is an absolute desert, but there is a gradual increase in precipitation through central Chile until it reaches a rainfall in south Chile not surpassed by any extra-tropical region. The strong permanent high pressure area formed over the Pacific at about 30° dominates the climatic conditions of northern Chile, accounting for its northward flowing winds and consequently for the great aridity of the region. South of this high pressure area are the prevailing westerlies or better, northwesterlies, which correspond to the southwesterlies of the northern hemisphere, but are much stronger. In this belt are the terrific winds that sweep the mountain passes between Chile and Argentina. This belt, migrating with the seasons, may occasionally make its influence felt as far north as the region of Coquimbo, where it produces winter rains. At Santiago, this migration is shown in a winter rainfall (3.4 in. in July, 0 in. in January, annual 14.4 in.). In certain years or series of years this migration does not take place or goes on beyond the normal and the result is either great droughts or heavy rains. South of the southern tip of Chile is a belt made up of numerous low pressure areas, with unusually high barometric gradients, which produce very strong winds averaging over 30 m. per hour, and reaching velocities three or even four times as high. These moving low pressure areas give a constant succession of storms for which the passage around the Horn has been renowned ever since its discovery, and farther northward give the lower part of Chile its westerly winds and immense rainfall.

North Chile is quite the driest region of which there is any record. During a 21-year period Iquique had an average rainfall

of 1.5 mm. (0.6 inches) and Arica for a 19-year period had less than one-half as much. These averages do not represent normal conditions but show that North Chile is not entirely rainless. On the Andean slopes of this region, periodic summer rains fall as low as 8,000 ft. with occasional heavy snows. These may produce stream floods, which spread mud and gravel over the valley and give rise to temporary salt lakes. Needless to say such rains are calamitous; nitrates are destroyed, the work of the *saliteras* paralyzed, and the homes of the people, because of the poor mud roofs, practically ruined. This absolute desert condition does not change until in the latitude (27°) of Caldera or Copiapó, where a mean rainfall of about 15 mm. prevails. The rainfall increases rapidly to the south, being 141 mm. (5.6 inches) at La Serena (30°); 500 mm. at Valparaíso (33°). The increase southward is still fairly regular reaching 2,707 mm. (107 inches) at Valdivia (39° 50'). From here south, the rainfall is more or less uniform except for local modifications with the striking maximum of 5,379 mm. (216 inches) for south Chile at Balúa Felix (53°).

The Chilean rains definitely come from the west. The western Andean slopes are wetter than the valley areas in all latitudes, and this is very noticeable even on the Andean slope of the northern desert region, where a rainfall map, however, shows all of Chile north of 31° with less than 10 inches. This dry area thrusts a finger down the central valley nearly as far south as Santiago. The 10 to 20 in. rainfall area, whose southern coastal limit is at Valparaíso, sends a strong arm down the valley nearly as far as Concepción, with a rain belt on either side of 20-40 in. and with a belt along the western slope of the Andes, overlooking the beautiful agricultural valley, of 40 to 80 inches. This belted arrangement is still more marked in the southern rainy section. The various islands and embayments show a rainfall of 80-200 in., the mountainous area directly to the east has a precipitation of over 200 in., while over in Argentina the rainfall gradually decreases again to less than 20 inches.

Irrigation is needed throughout the central valley, not only because of the low rainfall but more especially because the greater part occurs in the winter. This discrepancy becomes less marked from north to south. At La Serena over 98% of the rain comes in the six winter months and 82% in the three colder months. The percentages at Santiago for the same periods are respectively 90 and 73; for Concepción 83 and 61. Even at Magallanes 61% of the precipitation is during the six winter months. This seasonal distribution has given Chile an irrigated agriculture with an intensive rather than an extensive use of the land and with the climatic life of the Mediterranean.

In general, for its latitude, the temperature is low. The cold Humboldt Current, which strikes Chile at about 40° S., sends a branch northward along the entire coast, and keeps the temperatures down and very uniform. The average summer temperature, even at Arica, does not rise above 75° F. Similarly the mean at Iquique is only 66° F, and at Antofagasta 65° F, although southward the temperature is somewhat lower as at Valparaíso, where it is only 58° F. At the latter place, the mean monthly temperature varies from 63.5° F in summer to 52° F in winter, and the thermometer seldom rises to 85° or falls below 38°. Santiago at an altitude of 1,740 feet has recorded extremes of 96° F and 25° F, and on rare occasions snow falls in the city. At Valdivia in the southern end of the central valley, January is the warmest month with 61.5° F and July the coldest with 45° F. Due to the winter rainfall and the attendant cloudiness, the sensible winter temperature is much lower than the records indicate; and the general consensus of opinion is that, in spite of its excessive humidity, the climate of the inhabited parts of the country is conducive to health.

Vegetation.—Chile's isolation by desert and high mountain ranges has given it a number of distinct species of plants not found elsewhere. The indigenous flora of Chile, however, does not show the great variety that the wide range in latitude would seem to indicate. Although a goodly part of the country may be classified as lying well within the tropics, yet because of the arid wastes in the north, no part of the Chilean vegetation is to be considered tropical. The north is absolutely barren along the

coast from the extreme north to the region of the Loa, but in the oases and along the stream courses there thrives the Algarroba tree (*Prosopis*) with its tiny yellow flowers in the spring and its nutritious seedpods later, also the Chañar (*Gourliea*) one of the leguminaceae. One of the more striking is the Tamarugos (*Prosopis tamarugo*) which gives its name to that stretch of desert. The western slopes of the northern Andes produce certain nutritious grasses besides the *tola* brush and *ichu* grass. Farther south the Cacti become common. In Coquimbo, from the sea to the Andes, the *quiscales* form an effective covering but in addition a variety of vegetable forms thrive and afford some pasturage. In this section also are to be found large numbers of bulbous plants with their showy colourful blooms.

To some degree Central Chile presents a transitional flora between the north and the south, but it also has a number of distinct species of its own. Among the most familiar of these are the Espino (*Acacia*) with its twisted limbs especially prized for the excellent charcoal made from its wood; the Colihuai (*Colliguaya*) with its milky sap; and the thorny Trevu (*Trevoa*) one of the rhamnaceae. Mixed clumps of these give a safe asylum from grazing livestock to a host of tender flowering plants. The evergreen largely predominates here, and the dense dark foliage of the *Peumo* (*Cryptocarya*) is commonly conspicuous together with the *Quillai* (*Quillaja*) another characteristic evergreen. The Coquito palm (*Jubaca*) was once very abundant but has been almost completely destroyed by collectors of its sweetened sap. One of the most striking trees is the *Piñon*, Chilean pine (*Araucaria imbricata*), which often grows to a height of 100 ft., and is highly prized by the natives for its nuts, which are small but have a very attractive flavour.

When the Spaniards first visited Chile, the southern forests extended northward to the region of Santiago; from here on north was the semi-arid bush land. The good lands now have been cleared. The true forests of Chile may be said to be south of the Bio-Bio; rough estimates of the timbered areas vary from 40,000,000 to 50,000,000 acres. South of Valdivia is a vast forested region of which little information is available. Among the dominant types of commercial woods are the various species of conifers (*Podocarpus*, *Araucaria*, *Fitzroya*, *Libocedrus*); the laurels (*Billota*, *Cryptocarya*, *Persea*); the magnolias (*Drimys*); and the beech-like group (*Nothofagus*) of many local kinds and names. Trees become smaller and more stunted to the south, until at the Straits of Magellan only shrubs prevail and the altitude of the tree line is below 2,000 feet.

Fauna.—The animal life of Chile is limited to relatively few forms. Both the north arid region and the south humid region are unfavourable to the development of many species or numbers. The largest of the mammals, the *pangí* or puma (*Felis concolor*), extends its range down to the Straits of Magellan. Of the three species of wildcats the *guina* and the *colo* are the most common; of the foxes, the *chilla* (*C. azerae*) is small and considered stupid, the *culpeo* (*C. magellanicus*) is much the larger of the two; and of the other smaller forms the *coyupú*, or nutria, sometimes called the South American beaver, and the chinchilla (*Chinchilla naniger*) are the most important because of their excellent furs. The last named with its much prized skins is fast disappearing. Of the ruminants, the Guanaco, one of the camels closely related to the llama, although a plains animal, is now found only in the mountainous areas. The deer are small and nearly extinct. The *huemul* (*C. chilensis*), appears on the Chilean escutcheon, and the *pudu*, a small animal with branching horns is found only in the south, especially on the island of Chiloé. The bird life is much more abundant. The hawks and owls seem especially numerous. Unusually rich is the southern part of the country in wading and swimming birds, especially geese, ducks, swans, cormorants, ibises, bitterns, rails, red-beaks, curlew, snipe, plover and moorhens. The smaller singing birds are found also in great numbers.

(W. H. Hs.)

Population.—Quite commonly Chile is spoken of as a "white man's country." This is true when compared with the plateau countries to the north, but the qualification is more a matter of class than of blood. There was abundant opportunity for mi-

segregation during the colonial period as the fierce Araucanian remained unconquered for three centuries and the conflict with him called for an endless succession of Spanish soldiers, who in turn left in their wake a large number of half breed children. From such unions came the foundation of the Chilean race. The mixture occurred so long ago that its results are now expressed in racial unity and common characteristics and are quite unnoticed in the country itself.

The Chilean population is definitely divided into two classes, those who do, and those who do not possess material and cultural wealth. To some degree the distinction is the result of racial admixture but more definitely it arises from differences in inheritance, in opportunity and in outlook. Nominally independent and working for wages the *roto*, or agricultural labourer, lacks vision or initiative. The *patron*, or landlord, who profits from his labours may, as landed proprietor, be a gentleman of culture, and of sufficient wealth to supply his own requirements and to educate his children abroad. He rarely seems to care how wretched his *inquilinos* (tenants) may be, although nearly always ready to help in times of special adversity.

THE GAUCHO (COWBOY). A FAMILIAR FIGURE IN THE AGRICULTURAL PROVINCES OF CENTRAL CHILE

In the south are the Araucanian Indians who proved such valiant and unconquerable foes during both the Inca and Spanish regimes. Their definite overthrow as an independent people came only in 1882 when seasoned troops from the battle fields of the north pushed through the *frontera* and put an end to their resistance. The Araucanian strain in Chilean blood is considerable although not as noticeable as the blood of other tribes for it has not resulted in deterioration. Pride in the Araucanian heritage is reflected even in the national anthem. About 80% of the Indians (105,000 in 1920) live in the provinces of Malleco and Cautín. Beyond lies Valdivia and Llanquihue. It is in this region that German colonists of the mid-century encountered extraordinary hardships. But they introduced much-needed handicrafts, iron and wood working, tanning, shoe making and the like, and soon drew large numbers of Chileans to their settlements. The Germanization of south Chile has not been a matter of sheer numbers but is due to a far reaching cultural influence that if more widespread might prove a great blessing. In the extreme south one still encounters some remnants of the Fuegians, an indigenous people of extremely low culture.

In other parts of the country a plentiful sprinkling of English, Irish and Scottish names denotes an infusion of North European blood that is still going on, while recently arrived Spaniards, Italians and Slavs bespeak a continued connection with South Europe. Chile has never attracted a large immigration. Only 2,851 naturalization papers were granted from 1890 to 1926, although this low average—about 77 per year—does not represent the total number of new comers. Of those nationalized the Germans were first, with 722, the Spaniards second, with 382, and the Peruvians third, with 365.

In the north the "Changos" may represent survivors of an earlier native stock. The nitrate plants have attracted some immigrants from Bolivia, who are not regarded, however, as particularly welcome or efficient labourers. Chile is now making an effort to bring back to its soil those expatriated citizens, estimated, but probably inaccurately, to number 120,000, who are largely located in southern Argentina. They are offered free lands and other inducements to settle in the newly created territory of Aysen. The slow increase in population is a cause for concern to the authorities. The surplus of births over deaths in 1921 was 23,598 and for 1925, 47,438. For the latter year the illegitimate births were reported as 360 out of each 1,000 born.

Provinces* and Population

(Census of 1920 and official estimate as of Jan. 1, 1926)

| Provinces | Area in sq. kilometres | Population | | Population per square kilometre |
|--------------------------|------------------------|----------------|------------------|---------------------------------|
| | | Census of 1920 | Estimated 1-1-26 | |
| Tacna | 24,000 | 38,912 | 42,817 | 1.8 |
| Tarapacá | 42,441 | 100,553 | 96,968 | 2.3 |
| Antofagasta | 120,963 | 172,330 | 194,981 | 1.6 |
| Atacama | 79,531 | 48,413 | 42,422 | 0.5 |
| Coquimbo | 36,509 | 160,256 | 154,373 | 4.2 |
| Aconcagua | 14,000 | 116,914 | 112,538 | 8.0 |
| Valparaíso | 4,598 | 320,398 | 335,493 | 73.0 |
| Santiago | 15,260 | 685,358 | 750,374 | 49.2 |
| O'Higgins | 5,617 | 118,591 | 128,241 | 22.8 |
| Colchagua | 9,973 | 166,342 | 169,094 | 17.0 |
| Curicó | 7,885 | 108,148 | 108,571 | 13.7 |
| Talca | 10,006 | 133,957 | 134,712 | 13.5 |
| Mañé | 7,281 | 113,231 | 114,373 | 15.7 |
| Linares | 10,279 | 119,284 | 123,025 | 12.0 |
| Nuble | 9,059 | 170,425 | 172,005 | 19.0 |
| Concepción | 8,579 | 246,670 | 257,980 | 30.1 |
| Arauco | 5,668 | 60,233 | 59,702 | 10.5 |
| Bio-Bio | 13,863 | 107,072 | 110,622 | 8.0 |
| Malleco | 8,555 | 121,429 | 125,885 | 14.7 |
| Cautín | 16,524 | 193,628 | 214,331 | 13.0 |
| Valdivia | 23,285 | 175,141 | 196,991 | 8.5 |
| Llanquihue | 90,066 | 137,206 | 149,557 | 1.7 |
| Chiloé | 18,074 | 110,348 | 118,697 | 6.6 |
| T. Magallanes | 168,800 | 28,960 | 33,422 | 0.2 |
| Whole Republic | 750,816 | 3,753,799 | 3,947,374 | 5.2 |

*Early in 1928 the province of Valparaíso was combined with Aconcagua and Llanquihue with Chiloé, while the territory included in O'Higgins, Curicó, Linares, Arauco, and Malleco was divided among neighbouring provinces, thus reducing the total number to sixteen. At this time the new territory of Aysen was created from the lower part of Llanquihue and upper Magallanes.

Government.—After experimenting for more than 30 years with a pseudo-parliamentary government, Chile in 1925 reverted to the "presidential" type. The constitution adopted in that year provides for direct elections, for suffrage and citizenship without class distinction, for the separation of Church and State, and for an independent president. It is evident from recent events that its success will depend more on direct action by this official than on strict constitutional procedure.

Technically Chile is a unitary republic with responsibility centralized in the president. He is elected for six years and is not re-eligible. Colonel Carlos Ibáñez was unopposed when elected as president of the republic in May, 1927, after having served as acting vice-president for a few months and after having for some time before that virtually directed government policy. A series of defalcations in the revenue districts, the growing deficits in the State railways and the increasing costs of the civil service gave point to his policy of retrenchment, reform, and increased productivity and led to a general acquiescence in the more arbitrary features of his rule.

The validity of a president's election is finally determined by a special tribunal made up of former presiding officers of the senate and chamber of deputies and members of the supreme and appellate courts. The president selects the members of the supreme court from a list of five proposed by the court itself, designates members of the courts of appeals, of which there are eight, from lists submitted by the supreme court, and appoints judges of first instance from lists submitted by the court of appeals in the jurisdiction concerned. He cannot remove judges but he is empowered to transfer them, when necessary, within the jurisdictions to which they belong. Judges are removable by a two-thirds vote of the supreme court.

The president names the *intendentes* of the provinces, the governors of departments, and *alcaldes* in municipalities or communes of more than 10,000 inhabitants. He also has the power to remove these officials and indirectly controls their subordinates. A new code is under consideration, which is designed to decentralize the

system still further and to give greater power in local affairs to the *intendentes* and governors. The taxpayers are empowered to name communal committees (*juntas de vecinos*), non-political in character, who advise in local administrative and economic matters.

Congress consists of a senate and chamber of deputies. The former is composed of 45 members, five from each of the nine groups of provinces into which the republic is divided. Each senator holds office for eight years, and half the seats are renewable at the end of four years. The chamber of deputies numbers 132 members, one for each 30,000 inhabitants or major fraction. Electors are registered citizens over 21 years who are able to read and write. The ordinary session of congress lasts from May 21 to Sept. 18. It passes on the budget but the president may increase or decrease items within the limits therein prescribed, but congress may by a two-thirds vote pass a bill over his veto. Members of the cabinet are ineligible for seats in congress, but may speak in its sessions. They are subject to impeachment by congress and to removal from office for cause.

Credit and Finance.—Chile's financial record has in general been creditable. The relatively large expenditures have been maintained by the nitrate revenues and the recent decrease of income from that source was little short of disastrous. Moreover for 30 years past the government has struggled with the problem of stabilizing its currency. The disturbances of 1924 and 1925 made further delay impossible. Acting upon advice of the Kemmerer commission (*see below, History*) the government adopted legislation which established the paper peso at a gold valuation of 6 d. (in place of the fanciful 18 d.), established a *Banco Central de Chile* with the exclusive right to issue paper money and with the power to regulate general credit, and placed the general banking interests under the supervision of a Superintendent and central commission. This central bank received from the government the conversion fund of 409 million pesos that it had been accumulating for 30 years and with the aid of this sum established its own credit, replaced a large portion of the outworn paper money, and met the difficulties caused by the business and political slump of 1926. The bank follows the Federal Reserve system of the United States and in its two years of operation has reduced by a third the discount rate for banks and for the public, has acted as fiscal agent for the government and as a general clearing house, and has kept within narrow range the fluctuations in exchange, besides showing a substantial profit.

The government has definitely bettered its own fiscal affairs. At the end of 1926 it faced a prospective deficit of 161,500,000 pesos. By cutting salaries and pensions, and reorganizing the system of internal revenues, in which extensive defalcations were discovered, and of the customs; by rigorously applying the tax laws and adhering to a fixed budget, the situation was greatly improved and with some recovery in general business and a foreign loan the year 1927 ended with a slight balance. The income for 1928 was estimated at 959,119,617 pesos.

The treasury-general in the Ministry of Finance now controls all receipts and expenditures throughout the country. A new officer, the controller general, audits all accounts. A new department of the ministry maintains close relations with the producers of nitrate and with mining. This is in keeping with the new policy to encourage business by tariffs, by shifting the burden of taxation and by undertaking public works. In accord with the last named policy, the government proposes for the next six years an extraordinary budget of 1,575,000,000 pesos to be raised by loans and to be devoted to railroads and highways, port and irrigation projects, water supply for cities and public buildings. In addition it has authorized a farm loan fund and an institute of industrial credit.

Education.—The present system received its initial impulse about the middle of the last century. To the efforts inaugurated by the notable publicists of that period were added the laws of 1879 and 1889. This combined legislation represented a commendable programme for the better classes and the cities. Within recent years, however, there has developed an insistent demand for the education of the unlettered country population and for im-

provements in the existing system, especially in the direction of practical training. The State has accomplished something in the matter of technical and commercial training and during recent years the Catholic University at Santiago and the Laical University of Concepción have substantially broadened higher instruction. Since 1920 the demands for reform have occasionally expressed themselves in extended student strikes, which likewise reflected the prevailing unrest. In response to this agitation, which was supported by a few substantial leaders and by an increasing number of educators who had been trained abroad, a commission was appointed in 1925 to draft a comprehensive programme. This plan, somewhat simplified in the ministry, was issued by decree in May, 1927. It aims to decentralize the administration of primary schools by placing more responsibility on the provinces, to separate the administration of secondary schools from that of the university, and to give the latter more freedom; and at the same time to integrate the system through councillors from its five (originally eight) branches, who represent the president, the administration and teachers, and related activities. The minister of education is to superintend the entire system. Originally it was planned to have this function performed by a separate, non-political appointee. The departments of the ministry are as follows: (1) the sub-secretaryship; (2) primary education; (3) secondary, humanistic and technical education; (4) university education; (5) artistic education and extension work. The councillors of these divisions exercise legislative and regulatory powers, while the directors of each, who confer with the minister, execute details and select personnel.

In 1920, out of a total population of 3,753,799, 50.3% were reported as able to read. This may be a liberal estimate, but it is about four times larger than in 1854. In 1924 67.2% of the estimated scholastic population (6 to 14 years) of 888,683 were receiving instruction. This marked an increase of about 13% since 1918. Under State auspices, 510,145 were receiving instruction distributed as follows: 449,697 in primary schools, 55,760 in secondary schools, and 4,688 in higher institutions. Marked increases in all grades of instruction, public and private, characterize the past few years, except in normal and special schools. The new magnificently equipped Instituto Santa Maria of Valparaíso, a private college of engineering, made possible by a legacy from the late Federico Santa Maria, is a hopeful sign of awakened interest in Chile's educational needs. So is the recently completed national library, which reports a commendable list of general activities, in addition to the collections maintained for consultation, and the *Club de Señoras* of Santiago, which stimulates a healthy activity among women of the upper class. There were reported in 1924 627 periodicals of various types, of which 101 were of daily issue. Among these were an encouraging number devoted to professional and scientific interests and to social and labour propaganda.

Social Conditions.—Labour organizations before the 20th century were of the beneficiary type. The pioneer was the Typographical Union organized in 1853 and unions of this type, representing commercial and bank employees numbered 240 in 1900; in 1925, 600 with 90,000 members. After 1900, the workmen began to group themselves more definitely for defence and in 1909 organized the "Labour Federation of Chile" with provincial, departmental and federal councils, which took definite part in strikes

NATIVE OX CART IN THE MARKET PLACE AT SANTIAGO, CHILE

in the coal region and in the nitrate fields. Its programme embraced mutual aid, propaganda against alcohol and in behalf of education and an eight hour law, for arbitration of disputes, and for amicable relations with the public authorities. At its annual meeting in 1917 measures were taken to include in its membership all classes of labourers without distinction of sex. The Federation in 1919 adopted a programme that was frankly Communist. In 1921 it adhered to the Third International and

reorganized on the basis of six industrial councils (foods, manufactures, transportation, construction, public service, mines). Much of its programme was embodied in the social legislation of 1924-26.

Among other organizations represented in the country is the I.W.W. (Industrial Workers of the World, *q.v.*) especially strong among port labourers, the various unions of trainmen, a federation of printers, and a Catholic Federation of Labourers. These organizations, with exception of the first, are usually dubbed "yellow" by their more radical fellows, because of a tendency to cooperate with the government, while those that simply emphasize beneficiary measures are dubbed "white." Since 1920 all types of these unions have abandoned the policy of abstention from politics. In 1926 the anti-capitalist groups formed the *Union Social Republicana de los Asalariados de Chile* (U.S.R.A.Ch.) with the purpose to work for the "spiritual, social, political, and economic emancipation" of the employed class and for the organization of "a new society, based on justice, cooperation, and solidarity." This organization displayed increasing activity in political affairs until curbed by measures of the present president.

Up to 1924 employees were protected by general principles of law under the Code of 1857 and the commercial Code of 1867. Occasionally some organization was given definite juridical status. The I.W.W. lost this through resort to violence. About 1922 the Radical Party, representing the middle classes, began to favour legislation to put relations between capital and labour on a legal basis. The result was the law of Sept. 8, 1924, which created a series of general unions on a syndicalist base—the *Union de Empleados de Chile* (U.E.Ch.). This followed the tendency toward collective action shown during the preceding 15 years in the capital and the chief industrial centres. Its social tendencies appear in the formation of a Credit Bank, of a Cooperative Association, and of a Mutual Building Association. Its programme, since elaborated, is that labourers should work for their own emancipation, which means a living wage, an eight hour day, equal pay for men and women, and the nationalization of industry.

The primary and secondary teachers each have their separate professional organizations, and the former has occasionally shown a tendency to ally itself with elements opposed to the existing régime. The members of the medical profession, the engineers, and the architects have societies that occasionally assume a syndicalist attitude, although the Medical Society of Chile is strictly scientific and professional in its attitude. In 1921 the employers formed the *Asociación del Trabajo de Chile*, for which they immediately obtained government recognition. Their object is to co-ordinate and give solidarity to all measures "in questions which relate to labour or affect the natural evolution of industry, agriculture, and commerce." Both individuals and corporations may belong to this association.

Since 1900 there has been a growing interest in the labouring classes. A few leaders have directed their efforts to amelioration rather than prevention of specific evils, as is shown in "League against Alcoholism" and various agencies to care for destitute children. Of similar character were government measures against disease—measures which though largely unobserved date back to 1892. In 1906 the government passed a law for working class housing, which marks the first intervention by the government in a strictly social question. Later laws in favour of rest on Sunday (1907), the creation of the Office of Labour Statistics (1907), of laws for National Savings Banks (1912), for the care of abandoned infants (1912), for the regulation of conditions of labour including the labour of women and children, and providing for insurance against accidents (1912-16), on the railroads and in the nitrate establishments, and the law for obligatory primary education (1920), and for a fiscal pawnshop and for regulating maritime and other tasks, all point in the same direction. These culminated in the Decree Law of Sept. 8, 1924 which initiated a veritable era of social legislation. This regulated labour contracts, the day's work, salaries, hygienic conditions, conditions for women and children, security, arbitration, syndical organization, and methods of cooperation. Later laws created a special ministry for carrying out these enactments, which, however, has not always

been accorded a separate cabinet position. Much of this legislation has provoked bitter criticism, as being ill-advised and not adapted to those for whom it was intended nor to prevailing conditions in business.

The government also undertook an extensive programme for sanitary betterment. The inroads of alcoholism, of tuberculosis, and of venereal diseases; the extremely high death rate among infants, the lack of and poor quality of water supply and of sewerage systems gave Chile a death rate of about 40 per 1,000 that was hardly surpassed anywhere. Dr. J. D. Long of the United States Health Service in 1925 revised and put in force a sanitary code that put Chile far ahead of its neighbours. Among conspicuous features of his campaign was a widespread attempt to stamp out the pest of flies, to prevent commercialized prostitution, and to purify the water supply of the larger cities and give them better markets, a supply of pure milk and improved drainage. With the assistance of a group of local helpers much was done to improve conditions, despite the ever present financial shortage. This betterment has shown itself in a lowered death rate and in a marked appreciation of the dangers that menace the country through inadequate sanitation. As in the case of labour legislation, however, much of this legislation has proved too advanced for the people. (I. J. C.)

Mining.—In few countries are the activities of the people so restricted to certain regions as in Chile. Of these divisions none has its characteristics more sharply defined than the northern desert area with its unusual mineral riches, especially nitrates, which came into the possession of Chile as a result of the "War of the Pacific" (1879-83).

The nitrate beds lie between 19° and 26° S. and are found on the upland or "pampa" lying behind the coastal range at altitudes varying from 4,000 to 9,000 ft., but practically all the *oficinas* or nitrate works are below 7,500 feet. The workable beds, with a concentration of from 12 to 40% sodium nitrate, are non-continuous and vary in thickness from about 8 in. to 14 feet. The ordinary workings are by the open pit method and use only the richest *caliche*, or ore, so that unit areas produce variable amounts.

Of *caliche* mined only 55 to 75% of the sodium nitrate is recovered. A new method—the so-called "Guggenheim process"—promises a more complete recovery of nitrate, together with a considerable reduction of costs. The latter is effected by mining both high and low grade ores on a large scale and by reducing the product at a lower temperature. Running tests have shown a 94% recovery in *caliche* of 10% grade.

The origin of these immense deposits is more or less conjectural. The theories roughly fall into two groups, the organic and the inorganic. The origin through organic means are (1) from seaweed, (2) from guano and (3) from fixation of atmospheric nitrogen by bacteria. However, none of these theories is taken very seriously at the present time. The inorganic origin has been attributed to (1) the electric fixation of atmospheric nitrogen, and (2) to the concentration of the nitrates coming directly from tuffs and lava flows. The latter postulates, probably the more scientific, present fewer difficulties. Of this group, two theories stand out most prominently. The one (J. T. Singewald, Jr., and B. L. Miller: "The Genesis of the Chilean Nitrate Deposits," *Econ. Geol.*, XII., 1917) "is that the nitrate deposits have resulted from the accumulation, by means of evaporation of the minute nitrate content of the underground waters of the region. In other words, they represent a sort of efflorescence of soluble salts out of the ground water." The other (W. L. Whitehead: "The Chilean Nitrate Deposits," *Econ. Geol.*, IX., 1920) and later suggestion is that the source of the salts is from the Mesozoic rocks of the region which in extent correspond remarkably with the nitrate fields. Ammonium salts were probably sufficiently common in the volcanic rocks of the region to account for the present deposits. The process of reconcentration, through oxidation with alkaline earth, has been going on since early Pliocene time. Under desert conditions the salts derived from sources on steep slopes and hill-tops were carried down by dews, fogs, or infrequent rains to be deposited during evaporation in the gravels below. Here in periods

of high humidity, sodium nitrate, a deliquescent substance, was separated from the accompanying sodium chloride and sodium sulphate, to be precipitated during dry weather lower in the gravel.

The importance of these deposits to Chile can be gauged with little certainty. It has been estimated that between 1880 and 1910 Chile derived from the export tax on nitrate alone an average annual income of \$10,000,000 gold and since then one of twice that amount. For many years this nitrate trade has constituted more than half the total value of her exports, and the tax thereon of \$10.60 U.S. gold per ton collected by the government has constituted not only the largest item of its revenue, but also for many years has exceeded all other revenues combined. The prosperity of the whole country and the financial condition of the national treasury are to a very large measure determined by the condition of the nitrate industry. The nitrate fields, which in ordinary times give employment to over 40,000 workmen, offer one of the chief markets for Chilean produce. The annual output is upward of 2,000,000 tons valued at nearly \$100,000,000 U.S. gold. The effect of this easily acquired wealth, especially during the earlier years of the industry, is believed by many to have been actually harmful to Chile's sound development. The tendency to use this money for other than wealth producing investments has hindered the development of agriculture. Both capital and labour have naturally sought the more remunerative rewards of the nitrate regions. Since the World War, however, Chilean producers have been experiencing the reaction from the boom days of that period and have encountered keen competition from the manufacturers of synthetic nitrates. Some slight improvement in production after 1922 was followed by another decline that culminated in the disastrous year of 1926. Since then there has been a slight recovery, but Chile has failed to profit greatly from the increase in the general consumption of nitrate. In 1926 the country produced only about 25% of the world's nitrogen requirements, as contrasted with 64% in 1910, although from its nitrate reserves it could supply the world for several centuries. With free competition in selling, with a reduction in the export tax, and with the advantages offered by the "Guggenheim Process" in the working of low grade deposits, Chile, it is confidently believed, can compete with synthetic nitrate for many years to come.

In addition to nitrate, Chile is also rich in low grade copper deposits. Some of the richer ores were worked by the Spaniards as early as 1601 and by the Indians long before. In the latter half of the nineteenth century, Chile was a leading copper centre of the world, in 1876 producing 38% of the total supply. With the development of the copper deposits in the United States, Chilean production fell off to only 4% of the world total in 1906. Its rise in more recent years has been rapid and it now holds third rank with abundant prospects that it will at least retain this position. About 90% of Chilean copper is produced by two large American companies, operating at three centres: one in the north at Chuquicamata, another near Rancagua at El Teniente, and the third at Potrerillos near Chañaral. The Chuquicamata is one of the large scale mining operations in the world, working a low two per cent grade ore at an expense of seven or eight cents per pound. The copper reserve, the largest known, is conservatively estimated at 134 billion pounds. Although Chile's high grade iron reserves are estimated at over 900,000,000 tons, production of pig iron is almost nil due in large part to a lack of coking coal. Only one of the deposits, that at Cruz Grande, in the province of Coquimbo is being exploited and shipped to the United States under the control of the Bethlehem Steel Corporation. The mining and loading on steamers of this ore, on an unusually large scale, is considered a model of efficiency. Because of high grade and cheapness in its handling, these ores enter into competition with the great deposits in the United States.

The coals of Chile are noted for their quantity rather than their quality. They occur on the coast south of Concepcion and are of Tertiary age. They vary considerably in quantity, improving with depth. The product has been described as second class steamer coal, on the average 25% inferior to the Welsh product. There are four principal coal fields in the vicinity of the Bio-Bio,

of which the most important, Coronel and Lota, are worked under the sea by means of inclined drifts (*chiflones*) on the long wall system. In addition there is a small lignite deposit near Magallanes mined only for local use. Four-fifths of all the coal mined is used by the State railways and production in recent years, somewhat over a million tons annually, has been adversely affected by the increasing use of petroleum.

Agriculture.—The agriculture of Chile is confined almost wholly to the central valley. The available productive land is extremely limited, the amount devoted to cereals and other food crops being estimated at not more than four per cent of the total area of the country; orchards, vines, planted woodlands, grasses, and alfalfa (lucerne) occupy a somewhat smaller area; and the natural pasturage occupies a smaller area still. This 10 or 12% of the area, together with the 20 to 22% in natural forests and woodland, mostly in southern Chile, makes up the productive land—about $\frac{1}{3}$ of the total area of the country. The leading crops with their average acreage for 1921-1925 were wheat, 1,457,000 ac.; barley, 148,000 ac.; oats, 95,000 ac.; corn, 62,000 ac.; flax, 675 ac.; making a total of only slightly more than one per cent of the total area. Even with the acreage (about 275,000 ac.) devoted to grapes and orchards, these crops make up less than two per cent of the total.

By far the major part of the crop land is made possible only by irrigation, which was practised in limited areas of northern Chile, even during prehistoric times. The chief areas now under irrigation lie along the river terraces within the Cordillera, upon the piedmont to the west, or within the central valley. The available streams from the Loa to the Bio-bio are the chief sources of water. Some of the irrigation projects are of long standing and on a large scale, and carry water in canals over 100 m., besides furnishing extensive electric power. Many of the undertakings are privately owned, others belong to associations, and in recent years some very large projects have been financed by the government. The area served by the three largest canals aggregates 300,000 acres.

Although agriculture in the central valley lays the foundation for the social and political structure of the country and affords a large share of the products for local consumption, it has little influence on trade balances. Socially the bulk of the people are organized around the large feudal estates and suffer little change in condition whether crops are good or bad. The owner may be more or less affluent from year to year, but this adds little to his comforts or discomforts, and he always remains on the social and political register of the country. In the northern valleys maize is the chief food crop and besides there is a great variety of sub-tropical fruits. The best developed type of feudal estate may include some 250 ac. of irrigated fields and 2,000 ac. or more of hillside land, which offers excellent range for live stock during

METHOD OF HAULING DRINKING WATER OVER THE DRY PLAINS TO THE NITRATE FIELDS OF ANTOFAGASTA, CHILE

the rainy season. These *propriedades agricolas* are mixed farms producing a large variety of grains and fruits, and alfalfa, some horses and a larger number of cattle and sheep, but never many hogs. The growing of live stock on irrigated land, however, is not profitable. As a result Chile has less than half the cattle of Cuba and must depend upon Argentina for part of its meat supply. This source, owing to recent tariff changes, is being still further restricted. The relatively large number of sheep is accounted for by the big development in Magallanes where more than one-half of the sheep of the country are found. The central valley, so similar to that of California, favours the growing of fruits, but lacks a good market. A number of attempts have been made to develop one in the United States but shipments there, with a few exceptions, have not been successful. The chief gain of the Chilean farmer has come from his vineyards. The wine of the country is widely known throughout South America. The grape acreage ranks next to wheat and

is larger than that devoted to any other cereal, or to beans or alfalfa. Whether this is the cause or not, Chile is considered as more afflicted by alcoholism than any other South American country.

Although south Chile is the great forest section of the country, yet because of transportation problems relatively little of the output enters into its internal or external commerce. On the whole it has been found more economical to import timber products from the United States. Chilean forests were once very much more extensive than now but have been destroyed as an incumbrance, even in late years. Of the forested area, estimated at about 35,000,000 ac., at least two-thirds of it must be discounted because of the character of the woods or the type of country in which it is found. Only the province of Cautin can lay claim to first class forests.

Manufacturing.—Like other South American countries, Chile has not yet reached the industrial stage, although the Government has done much to stimulate local activity. Most of the manufacturing establishments are little more than workshops, for in the 3,196 factories listed in 1923, there were employed only 82,118 people—an average of 25 or 26 each. By far the most numerous group of factories and the one employing the greatest number of workmen was engaged in the preparation of foods. About one-third of these factories, with nearly one-half the people employed, are in the province of Santiago. Great strides have been made in the preparation of leather and in the use of up-to-date machinery for the manufacture of shoes, so that Chile is now largely supplied from the local output. The high tariffs of recent years have also done much to stimulate local production, especially of textiles. Much may be expected from the development of electrical power.

Commerce.—Although Chile ranks seventh in size among South American republics, it stands third in the value of its foreign commerce, being exceeded by Brazil and Argentina only. Its per capita trade, about \$100, is equal to that of Argentina and double that of Brazil, although only one-tenth the total of the latter. This is a striking result, for fully one-half of the population is made up of agricultural *rotos*, who are modest consumers.

By 1850 England, France and Germany had largely crowded Spain out of Chilean trade, and Valparaíso had become the leading port of the west coast. Lines of communication were developed with California and Australia, and the trade of Chile became a vital factor in its development. Gradually copper and silver became more important as exports. The nitrate deposits were opened up, but this trade was of slow growth until after the "War of the Pacific." In 1880 nitrate accounted for 30% of the Chilean exports, and in five years this increased to 60%. From then on up to the World War, the exportation of nitrate grew rapidly and made Chile rich. The years just preceding the war were banner years, due largely to the cumulative effect of mounting revenues, to which seemingly there was to be no end. This naturally encouraged a lavish expenditure of money.

The outbreak of the war and the blocking of the trade channels brought on a national crisis of unusual severity. Then as the war progressed unprecedented demands for nitrate and copper in the United States, together with the opening of the Panama canal (1914), brought to Chile a prosperity never before equalled. In three years the trade more than doubled and the export figure reached the high mark of \$278,000,000. With the close of the war, the market collapsed and the exports fell to the pre-war figure. Then with the short post-war boom the export trade reached the new height of \$284,000,000 for 1920. But hard times followed, the country passed through one financial crisis after another, the government changed hands, and in 1927 the people submitted, in an earnest hope for a return to former prosperity, to the control of an army dictator. The abandonment in April, 1927, of price-fixing by the Association of Nitrate Producers has brought about some renewal of activity in that trade.

The situation with respect to nitrate is unique. Although agricultural activities are vitally important to the bulk of the population, the economic position of Chile in world markets depends upon its mineral resources, which account for the major

part of its exports, and indirectly furnish the funds for most of the imports. The prosperity of the people, therefore, depends on an export trade, in which they take little part and over which they have little control. The dominance of the mineral products (more than 90% of the total) in export trade in 1921-23 is shown when nitrate accounts for 58% of the total, copper 21%, borax 3%, and other minor items of two per cent or less make up the rest.

The fluctuations of copper, the second largest item of export, have relatively little influence on the general prosperity of the country, as that commodity pays a local impost rather than a direct export tax. Practically all the export of iron, about 1,000,000 tons, comes from the Tofo mines, under the control of the Bethlehem-Chile Iron Mines Company.

After various minerals, mutton and wool rank first as exports. Their combined value in the total trade is exceeded only by nitrate and copper. Fully four-fifths of the sheep output comes from the hinterland of Magallanes and hence figures slightly in the trade of Central Chile. Of the other exports, wheat and flour fluctuate greatly from year to year, but average about 4% of the total export. The margin above the home demand comes only with a crop that is above normal. In certain years there is a slight exportation of barley, oats, peas, lentils, fruits, nuts and the like. The analysis of the trade clearly shows that a nation depending on minerals for 90% of its exports is one whose prosperity is not built on a firm foundation.

The import trade is largely made up of manufactured goods and may be grouped into three dominant classes: (1) iron and steel products, about 30%; (2) textiles, 25%; and (3) a host of miscellaneous products. In the import trade, nearly one-half (48% for 1922-24) of all products come from two countries, the United States and Great Britain. As with almost all South American countries, there is little interchange with neighbouring countries. One of the strong features of the trade has been its regular balance in favour of Chile, but on the whole the outlook is not particularly alluring. The remedy seems to lie in the establishing of a new class of small farm holdings under the control of enlightened *rotos*. With such a change in social order, there may arise a new industrial and commercial Chile.

Transport.—Railway construction started in the north under private auspices in 1850. The government road from Valparaíso to Santiago was first opened in 1863 and thereafter gradually extended southward to Puerto Montt. Chile's narrow width called for a strategic longitudinal "system" and the barren character of the country to the northward seemed to place the burden of construction on the government. In 1910 it definitely undertook the building of a line in that direction and the completion of the railroad to connect Arica with La Paz.

In spite of this activity, by which 61%, or 3,772 m. out of a total of 6,209, are State owned, the major portion of the northern railways are operated under private ownership or lease, and serve the mineral interests of that region. The Chilean railways are government owned primarily for strategic reasons. In accordance with the treaty with Bolivia, measures were under way in 1928 to turn over to the latter country that portion of the railway within its limits.

Those roads that are under private control are on the whole efficiently administered. The State owned roads, which up to 1926 uniformly showed a deficit and thereby contributed to the financial crisis of that year, have been criticised for faulty location, poor equipment, and high operating costs. Political pressure will account for many of these defects, which the present administration earnestly seeks to rectify, and to improve equipment on the lines already electrified between Valparaíso and the capital and to Los Andes and the Chilean portion of the Transandine, and to eliminate "graft," favouritism and unnecessary employees. Among the proposals for extraordinary expenditures during the next five years is one for 183,000,000 pesos for railroads.

Little was done for highways before the law of 1920, which embodies some of the best foreign stipulations. In 1923, 21,959 m. of public road were reported, of which some 3,030 m. were fit for automobiles. Such roads, of course, were near the large cities. Among other extraordinary expenditures the government suggests

some 150,000,000 pesos for roads.

The telegraph dates from 1851 and this enterprise, like the railroad and steamship service, owed its inception to William Wheelwright. For some time the telegraph was united with the postal service, then administered separately for about 40 years, and later amalgamated in 1920. It was disorganized during the revolt of 1891 and by the earthquakes of 1906 and of recent years. 16,183 m. of telegraph line were reported for 1924, of which 5,976 were under private control. A series of wireless stations from Arica to Magallanes (Punta Arenas) is in operation or under construction. In the same year 979 post offices handled 117,495,832 pieces of mail.

The sea still constitutes Chile's best highway. Much, therefore, has been done since 1910 in constructing docks, erecting breakwaters, and in other ways making ports more serviceable, and in directing roads and railways thither. Continuation work of this sort and new undertakings call for an extraordinary expenditure of 287,572,000 pesos during the next five years. A new department of harbour works has been added to the Naval Ministry. Subsidies have been provided for national vessels using the Panama canal and the Straits of Magellan and other measures adopted to stimulate a commercial marine. In this branch 13 vessels were reported in 1927 with a tonnage of 19,624. (I. J. C.)

Army.—Compulsory military service prevails in Chile. Every able-bodied man over 20 years of age is due to receive 12 months' training, and is, as a matter of fact, very rapidly made into good fighting material. Following the year's active service they belong to the first reserve for 12 years and to the second reserve till the completion of their 50th year. The active army in 1925 consisted of 14,735 enlisted men and 1,513 officers. The first-line reserve numbered about 225,000 men and the second-class reserve about 200,000. The active forces were grouped into four military districts each capable of furnishing a complete division. The army consisted of the following corps: sixteen regiments and three infantry battalions, eight cavalry regiments, five regiments and six artillery groups, one engineering regiment and five engineering battalions, five battalions of railway troops and two aviation groups. The army has been trained and organized largely on the German system. The spirit of the vast majority of the recruits facilitates the task of able officers. Discipline is good, the uniforms neat and weapons are of modern pattern and well kept. The cavalry, in particular, is conspicuous for its first class condition. The infantry are armed with a modified Mauser rifle, the cavalry with a carbine (of similar make) and lance and the field artillery with Krupp guns. The air service, introduced in 1918 under British instruction, is being steadily developed. Cadet, artillery, cavalry, engineering and infantry schools are maintained by the State; in 1924 a school for non-commissioned officers was formed. (X.)

Navy.—The birth of the Chilean navy may be said to have taken place when, in 1817, a Scotsman, Captain William Mackay, set out from Valparaiso in a launch "La Fortuna" and, aided by thick mist and growing darkness, captured a Spanish frigate and a brigantine at anchor in Arica bay. The leader of the patriot forces, Bernardo O'Higgins, followed up this success, and by the autumn of 1818 he had formed quite a useful little squadron.

Two ships, the "Lautaro" and "East Indiaman" (the latter converted into a 50-gun frigate) and the brigantine "Pueyrredon" had a fierce encounter with the Spanish frigate "Esmeralda" and the "Pezueta," which were blockading the coast. Captain George O'Brien, who came to Chile as mate of a British merchant ship, commanded the "Lautaro," which he ran alongside the "Esmeralda." Shouting "Viva Chile," he placed himself at the head of a boarding party of 25 men and attempted to take the Spanish ship. Unfortunately he was killed, and those that remained of the boarding party were forced into the sea but were rescued by the "Lautaro's" boats. Nevertheless, the enemy suffered severely and fled from Valparaiso.

Not long afterwards, a Chilean squadron, under Admiral Blanco Encalada, attacked and captured a number of Spanish ships in Talcahuano bay. In this enterprise three of the ships of the patriot fleet were commanded by Englishmen.

In Nov. 1818 Admiral Lord Cochrane arrived on the scene and, at the invitation of the Chilean government, took over command of all the naval forces. He had a brilliant record as a fighter and his personal charm and whole-hearted enthusiasm for the cause which he had espoused soon won him the loyal support of the officers and men of his fleet.

Cochrane led his command into a number of daring and successful adventures, including the assault and capture of Corral. But his crowning achievement was the capture of the "Esmeralda." This Spanish frigate had long been a source of danger and annoyance, and at the time was ensconced behind the batteries and other defences of Callao. Cochrane personally headed the attack, and, in spite of fierce opposition and being badly wounded, he succeeded in cutting out the "Esmeralda," taking her to sea, and anchoring her alongside his flagship, the "O'Higgins."

By the end of his four years' service in Chile, her fleet had destroyed or captured every Spanish ship on the coast and reduced their base, thus giving the country its independence. His name was perpetuated in a "Cochrane" which, in 1879, under Capt. Latorre, won a famous fight with the Peruvian ironclad "Huascar."

The principal units of the Chilean fleet of the present day are:—

| | |
|-------------------|--------------------|
| Battleships | 1 modern, 1 old. |
| Armoured Cruisers | 2 old. |
| Cruisers | 3 old. |
| Destroyers | 6 building (1928). |

Considerable interest is taken by the Chilean people in their navy, and the assistance of British naval officers is sought constantly to keep it efficient.

HISTORY

In the 15th century the Peruvian Indians invaded the country—even then known as Chile—and dominated it as far south as the Rapel river (34° 10' S.). Their control may have furthered the later conquest by the Spaniards. The latter made their first attempt to occupy the region under Diego de Almagro, associate and subsequent rival of Pizarro. After Almagro's death the conqueror of Peru granted Chile to his favourite aide, Pedro de Valdivia. That invader founded Santiago (Feb. 12, 1541), and after establishing other fortified towns north and south of that centre and east of the Andes, lost his life in a general uprising of the Araucanian Indians, under their celebrated *toque*, or war-chief, Cautopolican. The greater part of his settlements were destroyed, although La Serena and Concepción remained as the outposts of the future colony to the north and the south, while Cuyo held the same position east of the Andes.

The Colonial Period.—With this inauspicious beginning Chile entered upon its three centuries of colonial history. In such phases of its development as were affected by the administrative and commercial control of the homeland it differed in no wise from its neighbours. Its population took no part in political affairs, aside from membership in the town councils. It accepted ecclesiastical control in its scant educational facilities as well as in spiritual matters. It endured all the vagaries of Spain's trade restrictions, varied by the piratical and contraband practices of its enemies. Chile differed from other Spanish colonies in that its remote position forced upon the people a more thorough isolation, while continued conflicts with the Araucanians tended to harden the settlers, and the scarcity of precious metals turned them toward farming.

By the end of the 17th century this population numbered 100,000. A century later it approached a half million. This included 300,000 *mestizos* (mixed bloods), half as many *Criollos* ("Creoles," i.e., natives of European descent), some 20,000 *Peninsulares* (recently arrived Spaniards, among whom Basque immigrants from northern Spain formed an energetic commercial element), and a smattering of negroes and recently emancipated Indians. This hardy population had progressed far towards racial unity but the *mayorazgos*, a system of transmitting estates by entail, gave enhanced importance to a few leading families. The people, set down in the midst of resources that were barely

touched, were stimulated to activity by a bracing climate, but were pitifully handicapped by ignorance, isolation, and the lack of political experience.

Independence and Self-government.—None of the above conditions that hampered Chile in common with its fellow colonies provoked the movement for independence. Nor was this act due to the rise of the United States nor to the French Revolution. It was the intervention of Napoleon in Spain—an act that in 1808 threw each part of the Spanish monarchy on its own resources—that led Chile to take the first halting step toward self-government. This occurred on Sept. 18, 1810, when an open *cabildo* or general town meeting in Santiago accepted the resignation of the president-governor and in his stead elected a *junta* (board) of seven members.

JARS USED IN MAKING WINE

This act divided the people (not including, of course, the ignorant masses) into two general groups. The first, which was composed exclusively of Creoles was headed by the *cabildo*, or town council of Santiago. The *audiencia* headed the second, which largely represented peninsular interests. The former group wished to organize for local protection during the intervention and possibly for more complete self-government thereafter. The peninsulars followed reluctantly, for they preferred to keep intact the existing system which insured them special privileges.

The creole leaders gained their immediate point—a recognized position in the new *junta*, took measures for the defence of the province, opened its ports to general trade, abolished the *audiencia*, when that body encouraged a reactionary uprising, and summoned a national congress. By this time Concepción, under the leadership of Juan Martínez de Rozas, broke away from the conservative leaders of the Santiago *cabildo*. This split enabled an ambitious popular leader, José Miguel Carrera, to dissolve congress, some two months after it finally organized, banish Rozas, and assume dictatorial powers, but this did not occur before congress had assumed administrative control of the colony, broken relations with Peru, abolished slavery, established a press, encouraged education and suggested further important steps towards self-government—all in the name of the captive king. Affairs in Chile now assumed the aspect of civil war between those of its people who favoured the former autocracy, as represented by the viceroy of Peru, and those who espoused self-government under a more liberal monarchy. Owing to divisions among the autonomists, who called themselves partisans of Carrera or of Bernardo O'Higgins, who had superseded him, the royalists gained the upper hand at Rancagua, Oct. 7, 1814, and brought to an end that first phase of the Chilean War for independence known as *la patria vieja* (the Old Country).

Two and a half years of repression under the restored government effectually cured the Chilean people of further loyalty to Spain. During this period José de San Martín patiently gathered an army at Mendoza and led it early in 1817, across the Andes. With this force, in which O'Higgins commanded a contingent, he defeated the royalists at Chacabuco, on Feb. 12, and made his associate supreme director of Chile. Their first task was to meet the inevitable counter attack under Osorio, the victor of 1814, who surprised and routed the patriot forces at Cancha Rayada. But with a reorganized force San Martín met and crushed the royalists at Maipú, April 5, 1818. This victory made good the declaration of independence which had been formally proclaimed on the first anniversary of Chacabuco.

During the next 15 years Chile passed through a period of political uncertainty that fortunately was less prolonged and less anarchic than her neighbours experienced. For five years O'Higgins maintained a fairly efficient personal rule, slightly modified by constitutional offerings of his own devising. After his abdication in 1823 there followed a more unsteady dictatorship under Ramón Freire, which was modified in 1826 by an ill advised attempt at federalism and two years later by the liberal but

unworkable constitution of 1828. During this period the Spaniards were finally expelled from Chiloé and that island and the contiguous area incorporated with the country. Aided by a naval contingent under Lord Cochrane (earl of Dundonald) the Chileans united with other patriotic forces in freeing Peru and thus assuring their own security. Then followed recognition by Brazil, Mexico, the United States and Great Britain. Through the last named country Chile was enabled to float its first external loan.

In domestic affairs the country was less fortunate. A few social reforms, initiated by O'Higgins and Freire, did little to remove the discontent engendered by years of warfare, to counteract the hostility of the Church, or to straighten out financial tangles. Politics were almost wholly personal and merely served to reveal political incapacity. Matters reached a crisis in 1829 with the outbreak of civil strife between Freire, who seemed the only hope of liberalism, and Joaquín Prieto, a successful military chief whom the reactionaries accepted. The conflict was decided at Lircay, April 17, 1830, with the utter defeat of the Liberal forces.

This victory made Prieto president of Chile, but his chief minister, Diego Portales, became its controlling spirit. This conservative leader, the Alexander Hamilton of Chile, aimed at something more substantial than mere military control. He wished to establish the credit of the country and assure its orderly progress. He proposed to continue in power those aristocratic elements that had softened the rigours of colonial control and had kept the struggle for independence clear of unproductive radicalism. With the aid of the *Pelucos* ("Bigwigs"), he centred administration in a President of almost dictatorial powers, whose acts were subject to limited revision by Congress. It was this combination of aristocratic supervision with autocratic administration that constituted the main feature of the Constitution of 1833.

The Autocratic Republic (1831-61).—The government under the new constitution soon faced a series of intrigues that in 1835 called Portales from retirement, and forced the re-election of Prieto. In furthering his efforts to preserve the constitution and to develop the resources of the country Portales now systemized the revenues, reorganized the treasury and refunded the public debt. But the benefits of this policy were measurably neutralized by his severity. Further dissatisfaction was aroused by a conflict with the Peru-Bolivian confederation, in the midst of which a regiment stationed near Valparaíso revolted and seized and assassinated the dictatorial minister, June 6, 1837. His death, regarded as a national calamity, served to fix his policy upon the country more firmly than ever. The war that he had brought about ended with the overthrow of the confederation at Yungay (Jan. 20, 1839). This victory assured the predominance of Chile on the west coast and made its successful general, Manuel Bulnes, the next president.

The first half of Bulnes's double term (1841-51) was an era of conciliation, of material progress, and of cultural awakening. The public debt was liquidated and the customs better regulated. Steamship lines were established, coal mines were opened, and the output of copper and silver was greatly increased. Colonies of Germans were located in the south and in 1849 the straits of Magellan occupied. This last move provoked a series of boundary disputes with Argentina which were further complicated by similar controversies with Bolivia. Per contra Spain now recognized the independence of Chile, and Peru settled the debt—a legacy of the period of independence—that had helped provoke war between them.

Intellectual expression kept pace with material progress. The National Institute improved its course of instruction. In 1843 the University of Chile opened its doors under the direction of Andrés Bello, a naturalized Venezuelan who later codified the civil law of Chile and attempted to nationalize its language. The Argentine refugee, Domingo F. Sarmiento, headed the first Normal School (1842) and for several years served on the editorial staff of *El Mercurio*. Literary expression manifested itself especially in the press, where José Victorino Lastarria represented reviving liberalism, and Francisco Bilbao, more definitely the revolutionary philosophy of 1848. Growing demands for religious toleration led the State to legalize the marriage of dissenters and to exercise

some control over clerical appointments.

After two decades of effective rule the Conservative Party found its supremacy threatened when in 1850 it brought Manuel Montt forward as the successor of Bulnes. But the administration ruthlessly suppressed opposition, which culminated in an unsuccessful revolt, and ushered in the decennium (1851-61) which closes the "autocratic republic." Montt was a fit executive for the period. A pedantic devotion to law and order motivated his policy but once assured of these essentials he devoted himself to developing his country's resources. He introduced the telegraph, began the construction of railways, started the hall of congress and various public buildings, and encouraged the founding of savings banks, the Mortgage Loan Bank, and other financial institutions. Agriculture was aided by the suppression of tithes and of the *mayorazgos*, by the subdivision of rural properties, and by modifying the *alcabalas*. He provided for better primary instruction, for more normal schools, and for public libraries. The discovery of gold in California created for a few years a better market for Chilean flour, but later led to a disastrous financial reaction.

Montt's insistence upon the authority of the State provoked a controversy over the appointment of the archbishop of Santiago and split his party. In a quarrel over the budget the malcontents were joined by a new party—the Radical—and the combined opposition forced the president to reconstruct his cabinet. This incident was later interpreted as a step toward fixing its responsibility to Congress. When opposition in 1859 became open revolt, Montt with the aid of his efficient co-labourer, Antonio Varas, rigorously suppressed it. It was felt inadvisable, however, to force the election of the latter as his successor.

The Liberal Republic (1861-91).—Joaquín Pérez was a compromise president. He began his administration in a spirit of conciliation and supported by a fusion of Liberals and Conservatives carried it on for ten years without recourse to the "extraordinary faculties," which preceding presidents occasionally used. The opposition maintained by the "Montt-Varistas" (Nationalists) and by the Radicals, mollified by religious and civil concessions, finally secured a constitutional amendment against the re-election of the president. The Radicals also sponsored closer relations with their west coast neighbours, when in 1866 Chile was drawn into the war between Peru and Spain, of which the outstanding event was the wanton bombardment of Valparaíso by the Spanish fleet. The growth in public revenues, which were doubling each decade, permitted this administration

MAKING ROPE FROM HEMP FIBRE IN CHILE

to complete the railway between Valparaíso and the Capital and to increase expenditures for such public services as the police, the postoffice and highways. A new commercial code went into effect in 1867 and two years later was held the first National Exposition of Agriculture—both marks of a healthy expansion in production. Colonization was extended into the south at the expense of the Araucanians.

Federico Errázuriz Zañartu (1871-76) continued the record of Pérez for efficient public service. He pushed forward the construction of railways, improved the water front at Valparaíso and finished the edifices for congress, for the University, and for

the Agricultural Exposition. At the same time his colleague, Benjamin Vicuña Mackenna transformed and beautified Santiago. The opening of new silver mines and the exploitation of guano deposits and of nitrate greatly stimulated business activity. But still more significant were the political changes of the period. Such issues as the secularization of cemeteries, civil marriage, the separation of Church and State brought the Conservatives forward as champions of ecclesiastical privilege, with the Radicals, aided by a press that was practically free, as their chief opponents. Fundamental changes in the penal code and in the organic Law of Tribunals subjected clerics to civil procedure, restricted the "extraordinary faculties" of the president, and rendered those holding judicial appointments ineligible for other political offices. Amendments to the constitution enlarged the powers of the chamber of deputies, provided for the election of its members by cumulative voting, and made the ministry more thoroughly subject to congress.

His successor, Aníbal Pinto (1876-81) suspended specie payments to meet the economic crisis caused by the exportation of gold and silver, and in 1881 finally settled the long-standing dispute with Argentina over the straits of Magellan. The quarrel with Bolivia over the guano deposits at Atacama proved insoluble. An attempt had been made in 1866 to settle it by dividing the revenues of the disputed territory. The discovery of silver mines at Caracoles and of nitrate deposits near Antofagasta increased the tension and ultimately led to the War of the Pacific.

Hostilities began in 1879 with the occupation of Antofagasta by Chilean troops. Bolivia immediately declared war and appealed to Peru for aid under the terms of an alliance made in 1873. Chile rejected Peru's offer of mediation and declared war against both republics. The first stages of the conflict were marked by naval engagements at Iquique and at Angamos, Oct. 8, 1879. The latter victory gave Chile command of the sea. After brilliant campaigns the Chileans speedily occupied the province of Tarapacá and followed this with the capture of Arica. Here in Oct. 1880, the contestants met in conference under the auspices of the United States but failed to come to terms. Chile, determined to force a territorial indemnity, then transferred her arms to the vicinity of Lima and in Jan. 1881, after desperate fighting occupied the city. Then followed two years of desultory guerrilla warfare, after which the Peruvians brought together a government that in 1883 accepted the Treaty of Ancón. Under this pact Peru unconditionally ceded Tarapacá to Chile and gave that country control for ten years over Tacna and Arica. At the end of that period, according to the third article of the treaty, a plebiscite should determine whether the provinces were to continue under Chile or return to Peru, the country winning the plebiscite being then obligated to pay the other 10,000,000 pesos. In 1884 Chile and Bolivia agreed to a truce by which the latter yielded to Chile for an indefinite period the province of Antofagasta—its only outlet to the sea.

In the midst of hostilities Domingo Santa María succeeded to the presidency. While bringing the war to a close he also subdued the Araucanian Indians. These successes in the north and south increased the territory of the republic by a third. Within the five years of Santa María's administration (1881-86) the public revenues more than doubled and continued to increase. The government, therefore, was able to meet all existing obligations, to encourage immigration and aid agriculture and mining—in short, to do everything except redeem its paper money. The peso depreciated to about half its value; prices rose accordingly. Thus in a period of apparent national prosperity the masses of the people suffered greatly.

More significant than fiscal issues was the election of an archbishop in Santiago—an act which revived the fervid discussion of "theological reforms." The authorities secularized the cemeteries and recognized civil marriage by law, but failed to bring about the separation of Church and State. At the same time congress extended individual guarantees, assumed the power to override the president's veto by a two-thirds vote, curtailed the powers of local officials, and established manhood suffrage. Yet the president, as before, intervened in the following election and

despite prolonged opposition, secured the choice of his designated successor, José de Balmaceda (1886-91).

The new president was a reformer who showed a tendency to use autocratic methods. Yet at the outset he attempted to reconcile his enemies and even permitted them to name the archbishop. Substantial increases in the revenue, especially from the export tax on nitrates, enabled him to initiate a veritable "dissipation of progress," including commendable attention to educational affairs. The system of secondary and higher education had been revised under the law of 1879. Medical instruction was now improved and a pedagogical institute founded for the training of secondary teachers. In fiscal affairs a more just system of taxation was introduced, a tribunal of accounts created, and part of the public debt paid. But the government made no attempt to abandon the system of paper money. It supplied the army and navy with better equipment and made efforts to encourage immigration.

These improvements were accompanied by complaints of wastefulness and of unnecessary increases in the civil service. At this period also occurred extensive strikes among the labourers, due in part to the depreciation of the currency and to the introduction of workmen from abroad. These conditions gave rise to a new party—the Democrats. The old parties were thoroughly disorganized and at outs with the executive, despite his conciliatory attitude. Cabinets were formed and dissolved mechanically. The president used his influence to elect new members to congress, only to have them join the opposition. The real issue at stake was the election of 1891, which Balmaceda, as usual, planned to dominate in favour of a friend. Congress attempted to checkmate the scheme by adjourning in 1890, without voting supplies. Balmaceda thereupon selected a group of advisers headed by his favoured candidate and announced that he would collect taxes for 1891 under the budget of the preceding year. This step was clearly illegal, but the president's worst offence was his open challenge to the aristocratic and clerical influences that had hitherto dominated the country.

His opponents, who comprised a majority of both houses of congress, did not hesitate to declare themselves in revolt. Led by the vice president of the senate and the president of the chamber of deputies and supported by the navy under Capt. Jorge Montt, they fled northward and established themselves at Iquique. Utilizing the revenues of the nitrate fields, they recruited an army from the labourers and prepared to fight the dictatorial president. He in turn declared Montt and his levies traitors and raised a force of 40,000 men to combat them. He filled up Congress with his supporters and directed an election in June, when his friend Claudio Vicuña was chosen to succeed him. He aroused further vindictive feeling by the execution in August of several youths belonging to leading families of the country.

Meanwhile his enemies in the north sought to purchase a supply of arms in the United States. Their vessel, the "Itata," evaded the American authorities, but after reaching Chile was forced to return without landing its cargo. The revolutionists finally obtained arms from Europe with which they met and defeated the Balmacedists at Concon and then utterly overwhelmed them at Placilla. Their victory was largely due to the scattering of the president's forces, to treachery in his ranks, and especially to the resentment inspired by his recent arbitrary course. Balmaceda abdicated on the evening of his defeat, took refuge in the Argentine legation and there, on the evening of Sept. 18, the last day of his administration, committed suicide. The contest had cost 10,000 lives and had added materially to the public debt, but it apparently decided that Congress and not the president should control the country.

The Democratic Republic (1891-1924).—The triumphant Congressmen speedily restored order and in November elected their leader, Admiral Jorge Montt as president. The new president proved a straight-forward, conciliatory official. He and his associates extended amnesty to the greater part of their opponents and assumed the debts contracted by both factions in the late contest. Then they proceeded to consolidate the pretentious parliamentary régime for which they had contended. The Municipal Law of 1892 by which the victors hoped to provide more

definitely for local participation in affairs and to forestall further executive interference in elections, was accompanied by a new law of parliamentary incompatibility, which prevented any one drawing a salary from the State from holding a legislative office and definitely shifted the control of elections from the executive to Congress. Political campaigns were henceforth carried on by party groups, seven or more in number, whose leaders resided in the capital and directed the activities of their representatives in each of the communes into which the country was divided.

These party groups now became mere personal followings, which could determine action only through precarious combinations. In presidential elections, however, the parties generally formed themselves into two general groups—the Alliance and the Coalition—of which the former embraced the more liberal elements. Yet there was nothing fixed in these combinations. In 1896 the Coalition carried the election of Federico Errázuriz, son of the former president, by a very narrow majority; in 1901 the vote went the other way in favour of Germán Riesco and swung back again five years later.

At this election in 1906 certain groups that were disgusted with sterile political combinations united to form a "National Union." They proposed to bring about "administrative regeneration" in the government and fittingly chose as their candidate, Pedro Montt, son of the man whose earlier administration still suggested law and stability. Although Montt had been defeated in 1901 the "National Union" now put him into office by an overwhelming majority. But the new executive was unable to bring about the redemption of the currency and only after the greatest efforts was he authorized to start construction on the Longitudinal railway. On the completion of the Trans-Andine railway in 1910 President Montt, accompanied by a brilliant entourage, journeyed to Buenos Aires, where the presidents of Argentina and Chile celebrated together the common struggle for independence. In the midst of preparations for the return celebration in Santiago, the president fell ill and in August died while on his way to Europe. Montt's successor also died in September, and Emiliano Figueroa, head of the cabinet, presided over the centennial festivities, and directed the election for president, which took place a few days later. After a prolonged contest within their party the Liberals placed in nomination Ramón Barros Luco, a veteran publicist, whom the Conservatives accepted and who was elected without opposition; but this result did not insure administrative stability nor repress the growing influence of money. Cabinet changes occurred as frequently as before. Bribery, despite severe laws against it, replaced executive intervention as the controlling factor in all elections, and made procedure therein a matter of purchase and of fraud.

In respect to international affairs the quarter century that followed the Civil War presents a more flattering record. The resentment aroused against the United States over the "Itata Affair" led to the still more irritating "Baltimore incident," which was finally settled by Chile's offer of compensation. The Alsop claim, growing out of the war with Bolivia, was finally arbitrated in 1911 by King George V. With the turn of the century there was a recurrence of border quarrels with Argentina, in two regions—the Puna de Atacama in the north and the Patagonian area in the south. The former was settled in 1899 by arbitration of the American minister in Buenos Aires, but without appeasing popular agitation in either country. In May, 1902, the two countries signed treaties which provided for the arbitration of disputes between them, for naval equality during five years and for limitation of armaments. The last two points made this treaty a pioneer. Moreover each country was to remain neutral with respect to affairs upon the other's coast. Some months later the British king, who had been asked to arbitrate the dispute in Patagonia, announced his award, which proved to be a virtual division of the contested area. Thus was ended a controversy that had lasted more than a half century (1847-1902). In commemoration of this settlement the two nations later joined in erecting on their common boundary above the tunnel of the Trans-Andine railway the famous statue known as the "Christ of the Andes."

In 1904 Chile signed with Bolivia the pact of Santiago by which

the former gained full sovereignty in the Atacama region. A secret article of the treaty assured Bolivia an outlet through Tacna-Arica. As a temporary substitute for this corridor Chile agreed to construct a railway from Arica to La Paz (which was completed in 1915) and in 1928 to turn over to Bolivia the portion in the latter's territory. Meanwhile Bolivian goods were given free entry and shipment in bond at Arica. These arrangements created a better sentiment between the two peoples. Chile and Peru, however, could not agree upon terms for holding the plebiscite under the Treaty of Ancón. All attempts to arbitrate the question failed. Chile began, after 1908, to interpret the disputed clause as a disguised cession and in 1913 the two countries agreed to postpone for 20 years any further attempts to carry out its provisions. Through Chile's understanding with Brazil and Argentina and through the participation of the three in the controversies between the United States and Mexico, the country gained marked prestige in Pan American affairs.

The irredeemable paper money affected adversely the volume of trade, and caused a moratorium during the war scare of 1898. Industry which was checked by the Civil War showed a favourable turn before the end of the century. This process was hastened by the protective policy of the government and by its measures to encourage the colonization of the Magellan area and to develop its wool interests and gold washings. The financial crisis of 1907 gave a set back to industry, already suffering from the great earthquake of 1906. These successive disasters, however, affected the country less than had at first been feared.

The rise in the cost of living led to demands for increased salaries and wages—demands that in the case of workmen were not granted without frequent resort to strikes. A series of these in 1905 terrorized Santiago and led to bloodshed. Serious disturbances also marked outbreaks at Iquique in 1907 and later in the coal fields of Lota. A few publicists now began to call attention to the misery and squalor that afflicted the Chilean masses and to the general lack of public sanitation. Agricultural labourers in times of scarcity showed a tendency to migrate, especially to Argentina. Because of this continued public neglect the population of Chile failed to keep pace with its growth in wealth and productivity.

A better situation obtained in cultural activities. A freer press supplied both books and periodicals to wider circles of readers. Primary instruction, both public and private, received fresh impetus from new normal schools, while the Pedagogic Institute (founded in 1889) exerted a marked effect on secondary education. Progress was shown in the establishment of trade schools and in the betterment of professional instruction. A General Congress of Instruction, held in 1902, and a General Congress of Secondary Instruction held ten years later, greatly stimulated the production of didactic treatises and the development of a professional spirit. A reputable group of scientific writers and of historians, of literateurs and of artists registered the intellectual and social advance of the country and with these cultured and zealous Church officials kept pace.

In the presidential election of 1915 Chile was hampered both by disturbances caused by the World War and by local political strife. In spite of the unanimity that marked the choice of Barros Luco in 1910 and of his general conciliatory policy, partisan spirit showed itself in the intervening elections and forced numerous cabinet changes. Accordingly the Alliance and the Coalition now put forward separate candidates and thus precipitated an exciting campaign in which neither received an actual majority. Congress, with whom final decision rested, chose Juan Luis Sanfuentes, the candidate of the Coalition, who succeeded in reorganizing public administration, in improving the army and navy, in extending railroads, encouraging the commercial marine, constructing port works and public buildings, and beginning the National Library. These improvements were effected despite the grave financial and

CHILEAN DESERT CONVEYANCE ON TRACKS

industrial depression that rested upon the country during the early months of the war, and despite cabinet changes and the later renewal of difficulties with Peru.

Chile had already experienced some trouble in maintaining neutrality when Sanfuentes became president. The country was terribly affected by the loss of European markets. Prussian methods in the army and German scholars among her educators, not to mention a thrifty German population in southern Chile and extensive German business connections, inclined large sections of the people to favour the Central Powers. In 1915 the German cruiser "Dresden" was sunk by a British squadron while supposedly interned in Chilean waters. England apologized for the affront and owing to the clever management of Agustín Edwards, the Chilean minister in London, suffered no further trouble from the incident. Gradually as the war continued public opinion in Chile veered toward the Allies, but the government maintained its neutrality and continued therein after the United States entered the struggle. Nor did the country fail to reap material rewards from the increase in its trade which in 1916 surpassed that of any previous year and two years later had still further doubled in amount.

The difficulties of the war period were surpassed by those that followed the Armistice. Anti-Peruvian riots at Iquique and Antofagasta in 1918 caused the withdrawal of consular agents from both countries. In the following year Bolivia and Peru, encouraged by the attitude of President Wilson talked of carrying their grievances to Versailles or to Geneva. By 1920 Peru and Chile were on the verge of hostilities. A *coup d'état* in Bolivia, where Chile was supposed to be exercising too much influence, relieved the situation, and left affairs in train for a more definite *rapprochement* the following year. In the first assembly of the League of Nations Chile gained an important chairmanship and in 1922, its delegate, Agustín Edwards, presided over the assembly.

Post-war recovery was retarded by the slump in nitrate and the ensuing labour disturbances. In the midst of these difficulties occurred the memorable election of 1920. Arturo Alessandri, the candidate of the Liberal Alliance, had served with distinction in Congress and cabinet. He launched his candidacy in 1918 and based his platform on an extensive social programme. This precipitate act, typical of the man, increased his prestige as a candidate. As representative of the middle classes and the labour groups, he covered the country in a veritable whirlwind campaign. At the election on June 25, 1920, it was announced that he had received 179 electoral votes to 175 for his opponent. Numerous charges of fraud, however, cast doubt upon the result. The canvass of the voters rested with congress, where each chamber favoured a different candidate. There was a demand for a special court of honour to determine the dispute. In the face of popular clamour, which culminated in a general strike, congress appointed the court and on the basis of its decision gave Alessandri 177 valid votes against 176. The settling of the election by this method, probably saved the country from a revolutionary outbreak.

In his message of June 1, 1921, President Alessandri outlined a programme of political and social reform. He wished to improve the conditions of labour and the status of women; to decentralize administration, separate Church and State, change the parliamentary system, establish executive responsibility, and elect the president and vice president by popular vote. A split in the ranks of the Alliance (following a general election to the chamber of deputies) added to the strength of the Conservative groups. In despair at his failure to overcome political opposition and faced with adverse economic conditions Alessandri tendered his resignation Nov. 17, 1921, but was persuaded to continue in office. Some slight betterment in the nitrate industry eased labour conditions, while the adoption of a protocol for the arbitration of the Tacna-Arica dispute diverted attention from domestic difficulties. The Fifth Pan American Congress, which was held at Santiago in April and May, 1923, served momentarily to distract attention from pressing local problems; but fiscal and business affairs showed an alarming uncertainty that was further increased by continued manifestations of unrest among students and labourers.

Parliamentary government in Chile seemed hopeless.

Reform and Readjustment.—At the beginning of 1924 affairs in Chile were in an alarming state of uncertainty. Unsuccessful attempts were made to modify by general party agreement the ineffective parliamentary system, to hold a fair election for members of congress, and to carry out the presidential programme of reform. With the failure of these efforts, Alessandri determined at all cost to secure control of the reactionary senate. He personally took part in the campaign that preceded the March election and as a result of his intervention, coupled with an extensive but as it proved unnecessary use of military pressure, he carried both houses of congress and for the first time seemed in a position to control public policy.

Congress, however, failed to follow his urgings. The opponents of the administration plotted its overthrow. Unmindful of its increasing unpopularity congress, late in August, intensified the general unrest by proposing to pay its members. Thus it brought upon itself charges of gross selfishness as well as of general incapacity. Army officers attended the sessions of the senate in token of disapproval and in reply to a demand for their punishment forced, on Sept. 5, the installation of a military junta to direct affairs. The president at first agreed to accept its supervision in return for support of his programme but soon resigned and left the country. The *junta*, presided over by General Luis Altamirano, dissolved congress with evident public approval, proposed some fiscal measures, and issued a few "decree-laws" in the way of reform. Then its members seemed to fall under reactionary influences. In Feb. 1925, a second *coup d'état*, directed by the younger army officers, dismissed Gen. Altamirano and his colleagues and recalled Alessandri. A young cavalry officer, Major Carlos Ibáñez, took a conspicuous part in this overturn.

The recalled president received a delirious ovation. He had come back on condition that he be permitted to carry out his programme for political and social reform. His way was smoothed by an agreement between the Conservative and Radical parties for the separation of Church and State. The decision in the Tacna-Arica controversy, shortly handed down by President Coolidge, also promised to strengthen his cause. His first care was to prepare a new constitution. This task, after some consideration of a convention, was turned over to a general committee—hand picked, indeed, but fairly representing all shades of public opinion. A smaller committee, of which Alessandri was chairman, actually prepared the document, which was then submitted to popular vote along with an alternative proposal for a modified "parliamentary" system. The new pact, based on what may be termed "presidential" principles was overwhelmingly successful, although some political groups abstained from voting.

The selection of the new executive caused further difficulty. An attempt to present a single candidate failed. Then Colonel Ibáñez, who had been promoted and was then serving as minister of war, announced his candidacy, thereby disrupting the cabinet and forcing the president's resignation. In alarm at the prospect of military domination most of the political factions came to a belated agreement upon Señor Emiliano Figueroa as a joint candidate. He triumphed at the polls although the leader put forward at the last moment by the more radical elements received a large vote in the capital and industrial centres. In Santiago a general strike followed the election but the acting president, Señor Barros Borgoño, handled the situation firmly, and in Dec. 1925, turned the administration over to president-elect Figueroa.

Each shifting authority of this tumultuous year furthered measures to rehabilitate finances. Unable to secure domestic agreement as to methods, the government finally invited Professor E. W. Kemmerer, of Princeton university, and a group of associates, to study the situation. A decree-law of Sept. 1925, finally embodied the results of their investigation. This act thoroughly revised the fiscal system and created a national bank for the triple purpose of administering the finances of the government, of reducing general rates of interest, and of regulating the other banks of the country. Other decree-laws provided for extensive social legislation, including the regulation of labour conditions and of public health. With the promise of greater stability under the new con-

stitution, Chile seemed destined to experience an important social and industrial advance.

The new administration failed to meet expectations. For some months, indeed, President Figueroa held together a meritorious cabinet, but the legislative factions could not keep from tinkering with executive affairs. The Tacna-Arica plebiscite did not materialize and this failure rested heavily on the administration. Many features of the social programme were premature and still others proved unpopular. No serious friction occurred over the separation of Church and State, because under agreement, the government was to continue its ecclesiastical subsidies for five years longer. The national revenues failed to respond to the strain resting upon them.

Changes in 1926 in the ministry of foreign affairs and in that of finance failed to restore public confidence. The one point of stability in the midst of general uncertainty was the ministry of war, still directed by Colonel Ibáñez. A general disruption in the cabinet, late in the year, made the colonel its head, without depriving him, however, of his military control. This new position enabled him to establish a veritable dictatorship, under which Conservatives, Communists, Radicals, Liberals and Democrats were alike proscribed. By such measures he dominated congress and essayed to reform the judiciary, even proceeding to arrest, and finally to banish, the presiding judge of the supreme court, who was President Figueroa's brother.

Before this extreme measure was carried out the president himself quitted office. The executive duties thereby devolved upon Colonel Ibáñez, who continued more openly but not less effectively his policy of administrative reform. Extensive defalcations in the public revenues were then brought to light, giving point to his programme and leading to general acquiescence in its severity. All branches of the public service, including the railroads, were subjected to a thorough overhauling in the interests of economy and efficiency, and those responsible for abuses therein were removed from office and fined, banished or imprisoned. Useless public employees were dropped and thoroughgoing measures taken to balance the budget, to increase production, and to assure general prosperity. This combination of government initiative with private industry seemed necessary to rescue the country from its economic and administrative débâcle. The virtual dictator, Colonel Ibáñez, then stood for the presidency, was elected by an overwhelming majority, and in July 1927, entered office for a term of six years.

BIBLIOGRAPHY.—The most complete general work is that of Diego Barros Arana, *Historia general de Chile* (16 vols., Santiago, 1884-1902), which covers the period up to 1830 and is virtually continued in his *Un decenio de la historia de Chile, 1841-51*. The best brief account is the *Estudio de la Historia de Chile* by Luis Galdames (6th ed. Santiago, 1925). A. U. Hancock's *History of Chile* is still the only available English text but H. C. Evans Jr., in *Chile and its Relation with the United States* (Durham, N.C., 1927), summarizes clearly the major phases of the country's development.

M. L. Amunátegui contributes for the colonial period the *Descubrimiento y conquista de Chile* (Santiago 1885) and *Los Precursores de la independencia de Chile* (1870) and numerous other studies. Abbe Eyzaguirre's *Histoire du Chile* (Lille, 1855) deals with the Church during this period while Horacio Lara's *Cronica de la Araucania* is devoted to the Indians. Crescente Errázuriz, *Historia de Chile* (Santiago 1911-12) treats of the conquest by Valdivia and the period immediately following. The monumental editorial works of José Toribio Medina, *Colección de documentos inéditos para la historia de Chile* (Santiago 1888-1902), his *Cosas de la colonia* (Santiago, 1889) and his *Colección de historiadores i de documentos relativos a la independencia de Chile* (Santiago, 1900-14) form a veritable mine for research on the colonial and revolutionary periods. His *Biblioteca hispano-americana*, 1493-1810 (Santiago, 1898-1907) is a detailed bibliography in seven volumes. Ramón Brisenó, *Memoria historico-crítica del derecho público chileno* (Santiago, 1849) is still the standard work on the early constitutions of Chile.

A. Chisholm, *The Independence of Chile*, reviews the struggle against Spain. A. Edwards, *Bosquejo histórico de los partidos políticos chilenos* (Santiago, 1903) and his *La fronda aristocrática* (Santiago, 1928) review the struggle and subsequent national events. L. Galdames presents a detailed study of certain phases of the period in *La evolución constitucional de Chile*, vol. i. (Santiago, 1926). The *Historia general de la república de Chile* (Santiago 1866-82) by B. Vicuña Mackenna and collaborators still has an important place for the revolutionary period. The same author's *Vida de O'Higgins* (Santiago 1882) and his

Don Diego Portales (Santiago?) are useful supplemental works. Thomas Cochran, Earl of Dundonald, *Narrative of Services, etc.* (London, 1859) treats of events from the viewpoint of the outsider.

R. Sotomayor Valdés, *Historia de Chile, 1831-71* (Santiago, 1875) covers less than a decade of the period indicated. P. B. Figueroa, *Historia de la revolución constituyente, 1857-59* (Santiago?); F. Fonch, *Chile in der Gegenwart* (Berlin, 1870); Sir Thomas Holdich, *Countries of the King's Award* (London, 1904); I. Errázuriz, *Historia de la administración Errázuriz* (Santiago, 1887?); Joaquín Nabuco, *Balmaceda* (Santiago, 1914); B. Arana, *La Guerra del Pacífico* (Santiago, 1887?); F. Velasco, *Memorias sobre la revolución de 1891* (Santiago, 1926); C. Walker Martínez, *La Administración de Santa María* (Santiago, 1888-89), are works devoted to individuals and men of importance in the national period. Ricardo Salas Edwards, *Balmaceda y el parlamentarismo en Chile* (Santiago, 1925) is the latest review of that epoch. A. Roldán, *El desarrollo constitucional de Chile* (Santiago, 1925) is the best text for the legal background. G. F. Scott Elliot, *Chile* (London, 1907) and L. E. Elliot (New York, 1922) are suggestive descriptive works. Occasional articles in *Revista Chilena de Historia* (Santiago, 1915-) and in *Chile* (New York, 1926-) have historical notes or treat of recent topics. The publications of the *United States Department of Commerce* and of the *British Department of Overseas Trade* are helpful for matters of trade and industry, and also *The South American Handbook* (London, annual). *The Sinopsis estadística de la República de Chile* presents a summary of all public activities. Convenient reviews of current events are given in *Revue de L'Amérique Latine* (Paris, 1922-) and in the *Bulletin of the Pan-American Union* (Washington, 19-). (W. H. Hs.; I. J. C.)

CHILEAN CIVIL WAR (1891). The Chilean civil war grew out of political dissensions between the president of Chile, J. M. Balmaceda, and his congress (see CHILE: History), and began in Jan. 1891. On the 6th, at Valparaíso, the political leaders of the Congressional Party went on board the ironclad "Blanco Encalada," and Capt. Jorge Montt of that vessel hoisted a broad pennant as commodore of the Congressional fleet. Preparations had long been made for the naval *pronunciamento*, and in the end but few vessels of the Chilean navy adhered to the cause of the "dictator" Balmaceda. But amongst these were two new and fast torpedo gunboats, "Almirante Condell" and "Almirante Lynch," and in European dockyards (incomplete) lay the most powerful vessel of the navy, the "Arturo Prat" and two fast cruisers. If these were secured by the Balmacedists the naval supremacy of the congress would be seriously challenged. The rank and file of the army remained faithful to the executive, and thus in the early part of the war the "Gobernistas," speaking broadly, possessed an army without a fleet, the congress a fleet without an army. Balmaceda hoped to create a navy; the congress took steps to recruit an army by taking its sympathizers on board the fleet. The first shot was fired, on Jan. 16, by the "Blanco" at the Valparaíso batteries, and landing parties from the warships engaged small parties of Government troops at various places during January and February. The dictator's principal forces were stationed in and about Iquique, Coquimbo, Valparaíso, Santiago and Concepción. The troops at Iquique and Coquimbo were necessarily isolated from the rest and from each other, and military operations began, as in the campaign of 1879 in this quarter, with a naval descent upon Pisagua followed by an advance inland to Dolores. The Congressional forces failed at first to make good their footing (Jan. 16-23), but, though defeated in two or three actions, they brought off many recruits and a quantity of munitions of war. On the 26th they retook Pisagua, and on Feb. 15, the Balmacedist commander, Eulogio Robles, who offered battle in the expectation of receiving reinforcements from Tacna, was completely defeated on the old battle-field of San Francisco. Robles fell back along the railway, called up troops from Iquique, and beat the invaders at Haura on the 17th, but Iquique in the meanwhile fell to the Congressional fleet on the 16th. The Pisagua line of operations was at once abandoned, and the military forces of the congress were moved by sea to Iquique, whence, under the command of Col. Estanislao Del Canto, they started inland. The battle of Pozo Almonte, fought on March 7, was desperately contested, but Del Canto was superior in number, and Robles was himself killed and his army dispersed. After this the other Balmacedist troops in the north gave up the struggle. Some were driven into Peru, others into Bolivia, and one column made a laborious retreat from Calama to Santiago, in the course of which it twice crossed the main chain of the Andes.

The Congressional *Junta de Gobierno* now established in Iquique prosecuted the war vigorously, and by the end of April the whole country, from the Peruvian border to the outposts of the Balmacedists at Coquimbo and La Serena, was in the hands of the "rebels." The *Junta* now began the formation of a properly organized army for the next campaign, which, it was believed universally on both sides, would be directed against Coquimbo. But in a few months the arrival of the new ships from Europe would reopen the struggle for command of the sea. The Congressional Party could no longer aim at a methodical conquest of successive provinces, but was compelled to attempt to crush the dictator at a blow. Where this blow was to fall was not decided up to the last moment, but the instrument which was to deliver it was prepared with all the care possible under the circumstances. Del Canto was made commander-in-chief, and an ex-Prussian officer, Emil Körner, chief of staff. Balmaceda could only wait upon events, but he prepared his forces as best he was able, and his *torpederas* constantly harried the Congressional navy. By the end of July Del Canto and Körner had done their work as well as time permitted, and early in August the troops prepared to embark, not for Coquimbo, but for Valparaíso itself.

The expedition by sea was admirably managed, and Quinteros, north of Valparaíso and not many miles out of range of its batteries was occupied on Aug. 20, 1891. Balmaceda was surprised, but acted promptly. The first battle was fought on the Aconcagua at Concon on the 21st. The eager infantry of the Congressional army forced the passage of the river and stormed the heights held by the Gobernistas. The killed and wounded of the Balmacedists numbered 1,600, and nearly all the prisoners, about 1,500 men, enrolled themselves in the rebel army, which thus more than made good its loss of 1,000 killed and wounded. The victors pressed on towards Valparaíso, but were soon brought up by the strong fortified position of the Balmacedist Gen. Barbosa at Viña del Mar, whither Balmaceda hurried up all available troops from Valparaíso and Santiago, and even from Concepción. Del Canto and Körner now resolved on a daring step. Supplies of all kinds were brought up from Quinteros to the front, and on Aug. 24, the army abandoned its line of communications and marched inland. The flank march was conducted with great skill, little opposition was encountered, and the rebels finally appeared to the south-east of Valparaíso. Here, on the 28th, took place the decisive battle of La Placilla. The splendid fighting qualities of the Congressional troops and the superior generalship of their leaders prevailed in the end over every obstacle. The Government army was practically annihilated. Valparaíso was occupied the same evening and Santiago soon afterwards. There was no further fighting, for so great was the effect of the battles of Concon and La Placilla that even the Coquimbo troops surrendered without firing a shot.

CHILE-PERUVIAN WAR (1879-82). The proximate cause of this war was the seizure, by the authorities of Bolivia, of the effects of the Chilean Nitrate Company at Antofagasta, then part of the Bolivian Province of Atacama. The first act of hostility was the despatch of 500 soldiers to protect Chilean interests at Antofagasta. This force, under Col. Sotomayor, landed and marched inland; the only resistance encountered was at Calama on the river Loa, where a handful of newly raised militia was routed (March 23, 1879). About the same time Chilean warships occupied Cobija and Tocopilla, and Sotomayor, after his victory at Calama, marched to the latter port. Bolivia had declared war on March 1, but Peru not till April 5: this delay gave the Chileans time to occupy every port on the Bolivian coast. Thus the Chilean admiral was able to proceed at once to the blockade of the southern ports of Peru, and in particular Iquique,

where there took place the first naval action of the war. On April 21, the Chilean sloop "Esmeralda" and the gunboat "Covadonga"—both small and weak ships—engaged the Peruvian heavy ironclads "Huascar" and "Independencia." After a hot fight the "Huascar" sank the "Esmeralda," but Carlos Condell in the "Covadonga" manoeuvred the "Independencia" aground and shelled her into a complete wreck. The Chileans now gave up the blockade and concentrated all their efforts on the destruction of the "Huascar," while the allies organized a field army in the neighbourhood of Tacna and a large Chilean force assembled at Antofagasta.

On Oct. 8, 1879, the "Huascar" was brought to action off Anagmas by the "Blanco Encalada," and the "Almirante Cochrane." Although hopelessly outmatched the "Huascar" made a brave fight. When she finally surrendered she had but one gun left in action, her fourth commander and three-quarters of her crew were killed and wounded, and the steering-gear had been shot away. The Peruvian navy had now ceased to exist. The Chileans resumed the blockade, and more active operations were soon undertaken. The whole force of the allies was about 20,000 men, scattered along the seaboard of Peru. The Chileans on the other hand had a striking force of 16,000 men in the neighbourhood of Antofagasta, and of this nearly half was embarked for Pisagua on Oct. 26. The expeditionary force landed, in the face of considerable opposition, on Nov. 2, and captured Pisagua. From Pisagua the Peruvians and Bolivians fell back along the railway to their reinforcements, and when some 10,000 men had been collected they moved forward to attack the Chilean position of San Francisco near Dolores station (Nov. 19). In the end the Chileans were victorious, but their only material gain was the possession of Iquique and the retreat of the allies, who fell back inland towards Tarapacá. The tardy pursuit of the Chileans ended in the battle of Tarapacá on the 27th, in which more men were killed than were wounded, the Chileans suffering a complete defeat. For some inexplicable reason the allies made no use of their victory, continued to retreat and left the Chileans in complete possession of the Tarapacá region. With this the campaign of 1879 ended. Chile had taken possession of the Bolivian seaboard and of the Peruvian province of Tarapacá, and had destroyed the hostile navy.

The objective of the Chileans in the second campaign was the Province of Tacna and the field force of the allies at Tacna and Arica. The invasion was again carried out by sea, and 12,000 Chileans were landed at Pacocha (Ylo), far to the north of Arica. Careful preparations were made for a desert march, and on March 12, 1880, the advanced corps started inland for Moquegua, which was occupied on the 20th. Near Moquegua the Peruvians, some 2,000 strong, took up an unusually strong position in the defile of Cuesta de los Angeles. But the great numerical superiority of the assailants enabled them to turn the flanks and press the front of the Peruvian position, and after a severe struggle the defence collapsed (March 22). In April the army began its advance southward from Moquegua to Tacna. Arica was also watched, and the blockade was extended north of Lima. The land campaign had in the meanwhile culminated in the battle of Tacna (May 26), in which the Chileans attacked at first in several disconnected bodies, and suffered severely until all their forces came on the field. Then a combined advance carried all before it. The allies engaged under Gen. Narciso Campero, the new president of Bolivia, lost nearly 3,000 men, and the Chileans, commanded by Manuel Baquedano, lost 2,000 out of 8,500 on the field. The defeated army was completely dissolved, and it only remained for the Chileans to march on Arica from the land side. The navy co-operated with its long-range guns, on June 7 a general assault was made, and before nightfall the whole of the defences were in the hands of the Chileans. Their second campaign had given them entire possession of another strip of Peru (from Pisagua to Ylo), and they had shown themselves greatly superior, both in courage and leadership, to their opponents.

The Chilean army was reorganized during the summer, and prepared for its next operation, this time against Lima itself. Gen. Baquedano was in command. The leading troops disembarked at

Pisco on Nov. 18, 1880, and the whole army was ready to move against the defences of Lima six weeks later. These defences consisted of two distinct positions, Chorrillos and Miraflores, the latter being about 4,000 yd. outside Lima. The first line of defence was attacked by Baquedano on Jan. 13, 1881. The defenders had 22,000 men in the lines, the Chileans engaged about 24,000. The battle of Chorrillos ended in the complete defeat of the Peruvians, less than a quarter of whose army rallied behind the Miraflores defences. Two days later took place the battle of Miraflores. Here the defences were very strong and the action began with a daring counter-attack by some Peruvians. Neither party had intended to fight a battle, for negotiations were in progress, but the action quickly became general. Its result was, as before, the complete dissolution of the defending army. Lima, incapable of defence, was occupied by the invaders on the 17th, and on the 18th Callao surrendered. The resistance of the Peruvians was so far broken that Chile left only a small army of occupation to deal with the remnants of their army. The last engagement took place at Caxacamara in Sept. 1882, when the Peruvians won an unimportant success.

CHILI or **CHILES**, the pods of several kinds of peppers, notably the capsicum, used as a condiment. In Mexico a dish of meat and beans, called *chili con carne*, is highly flavoured with chili. Chiles are generally considered too "hot" for northern dishes, but in tropical countries they are used in many ways to flavour native dishes.

CHILIA, a town of Bessarabia, Rumania, in the Department of Ismail, and on the Chilia branch of the Danube. Pop. (1924), 20,000. Chilia is a small fishing centre and port of some historical interest. Anciently known as Chilia, Chele or Lycostomium, it was a place of banishment for Byzantine political dignitaries in the 12th–13th centuries, a Genoese trading settlement 1381–1403, then Wallachian, Moldavian and Hungarian, and taken by Turkey in 1484. Under the Turks it was a strong fortress, with a largely Tatar population. It was taken by Russia in 1812.

CHILIASM, the belief that Christ will return to reign for a thousand years (from Gr. *χίλιας*, *χίλιοι*, a thousand), the doctrine of the Millennium (*q.v.*).

CHILLÁN, a city and the capital of the province of Nuble, in the southern part of central Chile, 246 m. by rail south-south-west of Santiago and about 56 m. direct (108 by rail) north-east of Concepción. Pop. (1920) 30,881. Chillán is one of the most active commercial cities of central Chile, and is surrounded by a rich agricultural and grazing country. Chillán was founded by Ruiz de Gamboa in 1594. Its present site was chosen in 1836. The original site, known as Chillán Viejo, forms a suburb of the new city. The hot sulphur springs of Chillán, which were discovered in 1795, are about 45 m. east-south-east. They issue from the flanks of the "Volcán Viejo," about 7,000 ft. above sea-level. The highest temperature of the water issuing from these springs is a little over 135°. The principal volcanoes of the Chillán group are the Nevado (9,528 ft.) and the Viejo. After a repose of about two centuries the Nevado de Chillán broke out in eruption early in 1861 and caused great destruction. The eruption ceased in 1863, but broke out again in 1864.

CHILL HARDENING, the process of hardening the surface of a metal by rapidly cooling it while it is molten or at a very high temperature. Usually the chilling is done by plunging the object in a bath of water or oil. In the case of railway and other wagon and car wheels, a "chill mould" is used, consisting of a sand mould with the outer part (which forms the rim) made of cast iron. When the wheel is cast, the rim cools very rapidly because the iron part of the mould absorbs and conducts away the

heat from it, and the consequent chilling hardens the rim. Chill hardening is sometimes combined with case hardening. (See FOUNDRY; CASE HARDENING; IRON AND STEEL.)

CHILLIANWALLA, a village of British India in the Punjab, situated on the left bank of the river Jhelum, about 85m. N.W. of Lahore. It is memorable as the scene of a battle on Jan. 13, 1849, between a British force commanded by Lord Gough and the Sikh army under Sher Singh. The loss of the Sikhs was estimated at 4,000, while that of the British in killed and wounded amounted to 2,800, of whom nearly 1,000 were Europeans and 89 were British and 43 native officers. An obelisk erected at Chillianwalla by the British Government preserves the names of those who fell. (See SIKH WARS.)

CHILLICOTHE, a city of northern Missouri, U.S.A., on the Grand river, 80m. N.E. of Kansas City; the county seat of Livingston county. It is on Federal highways 36 and 65 and 23 other roads, and is served by the Burlington, the Chicago, Milwaukee, St. Paul and Pacific, and the Wabash railways. Pop. 6,772 in 1920, and was 8,177 in 1930 by the Federal census. Coal and limestone abound in the vicinity, and much live stock is raised. The city has various manufacturing industries, and is one of the principal assembling points for dairy products in the State. The State industrial school for girls is here.

Chillicothe was settled about 1830. The town was laid out in 1837 on land granted by the Federal Government, and the city was incorporated in 1855. A famous tavern of the '50s, kept by "Uncle Johnny" Graves, is now a beautiful private residence. A tablet on the county Court-house commemorates the death, in 1868, of Nelson Kneass, composer of the music for "Ben Bolt," who drifted here with a travelling theatrical troupe.

CHILLICOTHE, a city of Ohio, U.S.A., on the Scioto river, 50m. S. of Columbus; the county seat of Ross county. It is on Federal highways 23 and 50, and is served by the Baltimore and Ohio and the Norfolk and Western railways. The population in 1920 (91.5% native white) was 15,831, and was 18,340 in 1930 by Federal census. Chillicothe is the trade centre of a rich agricultural region and coal and iron are mined nearby. The city has railway construction and repair shops, large paper-mills and other manufacturing industries, with a total factory product in 1925 valued at \$10,307,059. There are ancient mounds in a State park 4m. north. Chillicothe was founded in 1796, near the site of a village of the Chillicothe Indians which had been destroyed in 1787 by Kentuckians. It was the capital of the North-west Territory in 1800-03, and the capital of Ohio in 1803-10 and 1812-16.

CHILLINGWORTH, WILLIAM (1602-1644), English divine and controversialist, was born at Oxford in Oct. 1602. In June 1618 he became a scholar of Trinity college, Oxford, and was made a fellow of his college in June 1628. He was persuaded by a Jesuit propagandist to embrace Catholicism and went to study at the Jesuit college at Douai. But his godfather, Laud, then bishop of London, recommended him to make an impartial enquiry into the claims of the two Churches. After a short stay he left Douai in 1631 and returned to Oxford. On grounds of Scripture and reason he at length declared for Protestantism but declined a preferment offered to him in 1635 by Sir Thomas Coventry, lord keeper of the great seal. He was in difficulty about subscribing the Thirty-nine Articles. In a letter to Gilbert Sheldon, then warden of All Souls, he declared that he was fully resolved on two points—that to say that the Fourth Commandment is a law of God appertaining to Christians is false and unlawful, and that the damnatory clauses in the Athanasian Creed are false and schismatical. His principal work, *The Religion of Protestants a Safe Way to Salvation; or, An Answer to a Book entitled "Mercy and Truth"* etc., published in 1637, was undertaken in defence of Dr. Christopher Potter, provost of Queen's college, Oxford.

The main argument of the *Religion of Protestants* is a vindication of the sole authority of the Bible in spiritual matters and of the free right of the individual conscience to interpret it. In 1638 Chillingworth was promoted to the chancellorship of the church of Sarum, with the prebend of Brixworth in Northamptonshire annexed to it. In the Civil War he served in the king's army at

the siege of Gloucester, inventing a siege engine. Shortly afterwards he accompanied Lord Hopton, general of the king's troops in the west, in his march, and he was taken prisoner at Arundel Castle by the parliamentary forces under Sir William Waller. He died at Chichester.

Besides his principal work Chillingworth wrote a number of smaller anti-Jesuit papers, published in the posthumous *Additional Discourses* (1687); and nine of his sermons have been preserved. In politics he was a zealous Royalist, asserting that even the unjust and tyrannous violence of princes may not be resisted, although it might be avoided in terms of the instruction, "when they persecute you in one city, flee into another." Chillingworth advocated toleration in an intolerant age.

BIBLIOGRAPHY.—The *Works* of Chillingworth were published in three volumes (Oxford, 1838); The Lambeth mss. Codd. Miscell. No. 943, contain 18 papers by him. See a *Life* by Rev. T. Birch, prefixed to the 1742 edition of Chillingworth's *Works*; and P. des Maizeaux, *The Life and Writings of W. Chillingworth* (1725).

CHILLIWACK, a town of British Columbia, Canada, on Fraser river, 70 m. E. of Vancouver. Pop. (1931) 2,461. It is the terminus of the British Columbia electric railway from Vancouver, is served also by the Canadian National railways, and is connected by ferry with Harrison Mills on the Canadian Pacific line. Saw-milling and timber manufactures, canning, mineral water and dairy-produce works are of growing importance. The fertile district surrounding the town, growing small fruit, etc., has about 8,000 inhabitants, and has been extended by the drainage of Sumas Lake (30,000 acres).

CHILOÉ, a province of southern Chile, and also the name of a large island off the Chilean coast forming part of the province. The province, area about 37,000 sq.m., pop. (1920) about 247,500 (including Llanquihue), is composed of three groups of islands, Chiloé, Guaitecas and Chonos, and a large body of the mainland, including since 1928 part of the former province of Llanquihue. The population is composed mainly of Indians. The capital of the province is Puerto Montt, the former capital of the province of Llanquihue, pop. (1920) 9,751. Other towns are Ancud or San Carlos, at the northern end of the island of Chiloé, on the sheltered bay of San Carlos, once frequented by whalers, pop. (1920) 4,295. Castro, on the eastern shore of Chiloé, is the oldest town of the island.

The island of Chiloé is a continuation of the western Chilean formation, the coast range appearing in the mountainous range of western Chiloé and the islands extending south along the coast. Between this coast range and the Andes, the gulfs of Chacao, or Ancud and Corcovado (average width, 30m.) separate the island from the mainland. Chiloé has an extreme length north to south of about 118m., and an average width of 35 to 40m., with an area of about 4,700 sq.m. There are several lakes on the island—Cucao, 12m. long, being the largest—and one small river, the Pudeto, in the northern part of the island, is celebrated as the scene of the last engagement in the war for independence, the Spanish retaining possession of Chiloé until 1826.

CHILON, of Sparta, son of Damagetus, one of the Seven Sages of Greece, flourished about the beginning of the 6th century B.C. In 560 (or 556) he acted as ephor, an office which he is even said to have founded. According to Chilon, the great virtue of man was prudence, or well-grounded judgment as to future events.

A collection of the sayings attributed to him will be found in F. W. Mullach, *Fragmenta Philosophorum Graecorum*, i.; see Herodotus, i. 69; Diogenes Laertius i. 68; Pausanias iii. 16, x. 24.

CHILPERIC, the name of two Frankish kings.

CHILPERIC I. (d. 584) was one of the sons of Clotaire I. Immediately after the death of his father in 561 he endeavoured to take possession of the whole kingdom, seized the treasure amassed in the royal town of Berny and entered Paris. His brothers, however, compelled him to divide the kingdom with them, and Soissons, together with Amiens, Arras, Cambrai, Thérouanne, Tournai, and Boulogne, fell to Chilperic's share, but on the death of Charibert in 567 his estates were augmented. When his brother Sigebert married Brunhilda, Chilperic also wished to make a brilliant marriage. He had already repudiated his first wife,

Audovera, and had taken as his concubine a serving-woman called Fredegond. He accordingly dismissed Fredegond, and married Brunhilda's sister, Galswintha. But he soon tired of his new partner, and one morning Galswintha was found strangled in her bed. A few days afterwards Chilperic married Fredegond. This murder was the cause of long and bloody wars, interspersed with truces, between Chilperic and Sigebert. In 575 Sigebert was assassinated by Fredegond at the very moment when he had Chilperic at his mercy. Chilperic retrieved his position, took from Austrasia Tours and Poitiers and some places in Aquitaine, and fostered discord in the kingdom of the east during the minority of Chilperic II. One day, however, while returning from the chase to the town of Chelles, Chilperic was stabbed to death.

Chilperic may be regarded as the type of Merovingian sovereigns. He was exceedingly anxious to extend the royal authority. He levied numerous imposts, and his fiscal measures provoked a great sedition at Limoges in 579. He wished to bring about the subjection of the church, and to this end sold bishoprics to the highest bidder, annulled the wills made in favour of the bishoprics and abbeys, and sought to impose upon his subjects a rationalistic conception of the Trinity. He pretended to some literary culture, and was the author of some halting verse. He even added letters to the Latin alphabet, and wished to have the mss. rewritten with the new characters. The wresting of Tours from Austrasia and the seizure of ecclesiastical property provoked the bitter hatred of Gregory of Tours, by whom Chilperic was stigmatized as the Nero and the Herod of his time.

See Sérésia, *L'Église et l'État sous les rois francs au VI^e siècle* (1888).

CHILPERIC II. (d. 720) was the son of Childeric II. He became king of Neustria in 715, on which occasion he changed his name from Daniel to Chilperic. At first he was a tool in the hands of Ragenfrid, the mayor of the palace. Charles Martel, however, overthrew Ragenfrid, accepted Chilperic as king of Neustria, and, on the death of Clotaire IV. set him over the whole kingdom. The young king died soon afterwards. (C. Pr.)

CHILTERN HILLS or **THE CHILTERNs**, a range of chalk hills in England, extending from south-west to north-east through part of Oxfordshire, Buckinghamshire and Bedfordshire. They form a well-marked escarpment, facing north-westwards, with a long south-eastern slope, and run from the Thames in the neighbourhood of Goring to the headwaters of its tributary the Lea between Dunstable and Hitchin, the crest line between these points being about 55 miles. But these hills are part of a larger chalk system, continuing the line of the White Horse hills from Berkshire, and themselves continued eastward by the East Anglian ridge, a series which represents the edge of the chalk rising from beneath the Eocene deposits of the London basin. The greatest elevation of the Chilterns is found in the centre from Watlington to Tring, where heights from 800 to 850 ft. are frequent. Westward towards the Thames gap the elevation falls away but little, but eastward the East Anglian ridge does not often exceed 500 ft. There are several passes through the Chilterns, followed by main roads and railways converging on London. The hills were formerly covered with beech, and there is still a local supply of this wood for the manufacture of chairs and other articles in the neighbourhood of Wycombe.

CHILTERN HUNDREDS. An old principle of English parliamentary law declared that a member of the House of Commons, once duly chosen, could not *resign* his seat. This rule was a relic of the days when the local gentry had to be compelled to serve in parliament. The only method, therefore, of avoiding the rule came to be by accepting an office of profit from the crown, a statute of 1707 enacting that every member accepting an office of profit from the crown should thereby vacate his seat, but should be capable of re-election, unless the office in question had been created since 1705, or had been otherwise declared to disqualify for a seat in parliament. Before this time the only course open to a member desiring to resign was to petition the House for its leave, but except in cases of incurable ill-health, the House always refused it. Among the posts of profit held by members of the House of Commons in the first half of the 18th century are

to be found the names of several crown stewardships, which apparently were not regarded as places of profit under the crown within the meaning of the act of 1707, for no seats were vacated by appointment to them. The first instance of the acceptance of such a stewardship vacating a seat was in 1740, when the house decided that Sir W. W. Wynn, on inheriting from his father, in virtue of a royal grant, the stewardship of the lordship and manor of Bromfield and Yale, and *ipso facto* vacated his seat. On the passing of the Place act of 1742, the idea of utilizing the appointment to certain crown stewardships (possibly suggested by Sir W. W. Wynn's case) as a pretext for enabling a member to resign his seat was carried into practice. These nominal stewardships were eight in number, but only two survived to be used in this way in contemporary practice—those of the Chilterns and Northstead; and when a member wishes to vacate his seat, he is accordingly spoken of as taking the Chiltern Hundreds.

The Chiltern Hundreds formed a bailiwick of the ordinary type. They are situated on the Chiltern hills, Buckinghamshire. The appointment of steward was first used for parliamentary purposes in 1750, the appointment being made by the chancellor of the exchequer (and at his discretion to grant or not), and the warrant bestowing on the holder "all wages, fees, allowances and other privileges and pre-eminences." Up to the 19th century there was a nominal salary of 20s. attached to the post. It was laid down in 1846 by the chancellor of the exchequer that the Chilterns could not be granted to more than one person in the same day, but this rule has not been strictly adhered to, for on four occasions subsequent to 1850 the Chilterns were granted twice on the same day. The Chilterns might be granted to members whether they had taken the oath or not, or during a recess, though in this case a new writ could not be issued until the House met again. Each new warrant expressly revoked the grant to the last holder, the new steward retaining it in his turn until another should be appointed.

See parliamentary paper—*Report from the Select Committee on House of Commons (Vacating of Seats)* (1894).

CHILWA (incorrectly **SHIRWA**), 15° 15' S., 35° 40' E.; a shallow lake of brackish water in the Nyasaland Protectorate abutting on Portuguese East Africa. Its area varies with the rainfall, but never exceeds 100 sq. miles. Formerly, at a period of higher level, the lake appears to have drained northward to the Lujenda branch of the Rovuma. There are four islands, one rising 500 ft. above the water level. The lake was discovered by Livingstone in 1859.

CHIMAERA. This term is used in botany to apply to certain types of plants formerly known as "graft-hybrids." The term graft-hybrid suggests a plant which is a true hybrid produced by grafting, *i.e.*, a plant produced by the fusion of cells derived respectively from the two plants grafted together. Such a union of cells would be of the nature of fertilization (*see* Cytology) and the offspring, having the characteristics of the two plants grafted, *i.e.*, the stock and scion, would be of composite origin and so might properly be called a graft-hybrid. The development of a hybrid plant in such a way is, however, entirely unknown. It is true that plants composite in nature and having some of the characteristics of the two plants employed may develop from the graft, but they arise in an entirely different way without fusion of cells. The term graft-hybrid which used to be applied to them has therefore been dropped and they are now called "plant-chimaeras" or simply "chimaeras." A chimaera was a mythological monster of composite nature, having the head of a lion, the body of a goat and the tail of a dragon. The plant chimaeras are truly of composite nature and origin.

These chimaeras, though not under this name, have been known in gardens for some time, but it is only comparatively recently that their nature has been understood. In 1825 a French horticulturist grafted a shoot of *Cytisus purpureus* (the ordinary English broom, *Cytisus scoparius*, is an allied species) on the trunk of the ordinary laburnum, *Laburnum vulgare*. M. Adam was very surprised to find that a shoot developing at the graft was intermediate in character between the two parents or, rather, showed some characters of *C. purpureus* and others of *L. vulgare*.

The original composite plant has been propagated vegetatively and is fairly common in gardens, being usually called *Cytisus Adami* or *Laburnum Adami* after its producer. It was supposed to be a "graft hybrid" as were also the so-called *Crataegomespilus* forms which arose at Bronveaux in Lorraine as a result of a graft between two different genera *Crataegus monogyna* and *Mespilus germanica*. In both cases it was observed that certain shoots on the composite plant would revert or throw back to the original forms, i.e., to *L. vulgare* or *C. purpureus* in the one case or to *C. monogyna* or *M. germanica* in the other. Another supposed case of a graft hybrid was that of the Bizzaria orange which it was presumed had arisen from a graft between *Citrus aurantium* (the ordinary orange) and *C. media*.

The Discovery of the Nature of "Graft Hybrids."—In 1907 our knowledge of this subject passed into a new phase. In that year H. Winkler published in Germany some experimental work on grafting *Solanum nigrum* (a common British plant with black berries sometimes known as black nightshade) as scion on *Solanum Lycopersicum* (the tomato) as stock. After the graft had taken, a transverse cut was made through it at the junction of the stems. From the surface of contact of the stock and scion a number of buds developed which grew out into new shoots. Most of these were just shoots of tomato or of nightshade, but one of them was composite in nature, having the characters of tomato on one side and of nightshade on the other. Some of the leaves which arose at the junction of the two halves had partly the characters of one species and partly of the other. Winkler very appropriately termed this shoot a *chimaera* since it was half of one species and half of another. In 1908 Winkler published the results of an examination of 268 grafts, between the same two species, which bore more than 3,000 shoots when cut across in the way described. Of these, five were chimaeras of the kind described the year before, but one was intermediate between the stock and scion, being rather nearer to the nightshade than the tomato. This shoot Winkler believed to be a real "graft-hybrid" to which he gave the name *Solanum tubingense* since it was produced at Tübingen. Next year he claimed to have produced several more graft-hybrids to which he gave special names, *S. Darwinianum*, *S. Gaertnerianum*, *S. proteus* and *S. Koelreuter*. It was found, however, that seedling plants (arising of course sexually from these forms) always reverted to the nearer parent, never producing hybrid seedlings. Again if the new forms were crossed with the nearer parent-form the product was always pure tomato or pure nightshade. This is not the behaviour which one would expect from a true hybrid.

Work on Variegated Plants.—In 1909 E. Baur published observations on variegated plants which shed a new light on the nature of the so-called graft-hybrids. It is well known that the garden geranium (really *Pelargonium zonale*) often shows leaves with a white margin. When examined microscopically it is found that there are two or three layers of colourless cells covering the internal green tissue, and these tissues are separated right up to the growing point so that the variegated *Pelargonium* plant body consists of a green core surrounded with a white sheath. To such a plant Baur gave the name *periclinal chimaera*, i.e., a chimaera in which one component invests the other. He further suggested that Winkler's so-called graft-hybrids between tomato and nightshade were also periclinal chimaeras, i.e., plants with a tomato sheath over a core of nightshade tissue or a sheath of nightshade over a core of tomato tissue. This would explain why these forms produce seedlings of either tomato or nightshade, since the sexual cells arise solely from the central tissue, the outer cells not being concerned. Baur also examined *Cytisus Adami* and the *Crataegomespilus* "hybrids" and found that they also were periclinal chimaeras. *Cytisus Adami* has a core or body of *Laburnum*

CHIMAERAS, PLANTS OF COMPOSITE NATURE AND ORIGIN

A. Cross section of grafted stock through point of union
B. Periclinal chimaera
C. and D. Sectorial chimaera. The portion in black represents the tissue of the scion and the unshaded portion the tissue of the stock

vulgare with a skin (epidermis) of *Cytisus purpureus*. In the other case the chimaeras have either a *Crataegus* core with a *Mespilus* skin (epidermis) or vice versa. Winkler on examining his so-called *Solanum* "hybrids" in the light of Baur's suggestion found that Baur was correct in his surmise. *Solanum tubingense* has a nightshade core and a tomato skin one layer thick (see Plate). *S. proteus* has also a nightshade core and a tomato skin but the skin is thicker, having two layers (see Plate). *S. Koelreuterianum* has a tomato core and a nightshade skin one layer thick (see Plate).

Classes of Chimaeras.—Winkler produced his chimaeras experimentally by "cleft grafting" of main shoots, a tongue of the scion being inserted in a cleft in the stock. When the two shoots had united the graft was cut across transversely. The relation of parts would then be as shown in fig. 1a where the black area represents the scion and the light area the stock. The cut surface of the graft produces "callus" (see GRAFT) and from this buds develop. Most of these are "pure" in origin since they arise from callus tissue which has developed from either stock or scion; but some may arise from callus, which is partly of stock and partly of scion origin, and these may give chimaeras. The tissues in the shoots arising from the buds of mixed origin may be arranged as in fig. 1b, which is a *periclinal chimaera*, or as in fig. 1c, which is a *sectorial chimaera*, only a section of the tissue in cross-section (the black portion) being of scion nature. The first chimaera Winkler produced was of this type, though in that case the chimaera was a "half and half" one. The third type shown in fig. 1d was formerly considered as sectorial, but it is really an incomplete periclinal for which the term *mericlinal* has been suggested (see bibliography under Jorgensen and Crane). True sectorial chimaeras are very rare, the plant first obtained by Winkler being of this type, as are also a few *Pelargoniums*. The periclinal type is quite common, e.g., *Cytisus Adami*, the forms of *Crataegomespilus*, *Pelargonium*, *Bouvardia*. The chimaera may be a whole plant or a shoot only or only a smaller portion such as a flower or fruit. In plants such as *Bouvardia*, which is of the complete periclinal type, we have the interesting result that shoot cuttings and root cuttings produce plants of different types; in one case the new plant arises from one set of tissues, in the other case from the other set. It has recently been shown that chimaeras are more common than was suspected. The tubers of certain varieties of the common potato are shown to be chimaeras. If the shoots developing from the normal eyes are rubbed off, the new one developing arises from deeper tissues and so from the other component of the chimaera, thus giving shoots of a different type.

BIBLIOGRAPHY.—The literature of this subject is largely in German. H. Winkler, "Ueber Propfbastarde und pflanzliche Chimären," *Berichte der deutschen botanische Gesellschaft* (1907); *ibid.* (1908); "Ueber das Wesen der Propfbastarde, Periklinchimären, und Hyperchimären," *ibid.* (1910). There is a good review of the literature up to 1911 in the *Botanical Gazette* (1911). For later papers in English, see W. Bateson, "Root Cuttings and Chimaeras," *Journal of Genetics* (Cambridge, 1916 and 1921); C. A. Jorgensen and M. B. Crane, "Formation and Morphology of *Solanum* Chimaeras," *ibid.* (1927).

(V. H. B.)

CHIMAERA. In Greek mythology a chimaera was a fire-breathing female monster resembling a lion in the fore part, a goat in the middle, and a dragon behind (*Iliad*, vi. 179). She devastated Caria and Lycia until finally she was slain by Bellerophon (q.v.). In art the Chimaera is usually represented as a lion, with a goat's head in the middle of the back, as in the bronze Chimaera of Arezzo (5th century). The word is now used generally to denote a fantastic idea or fiction of the imagination.

Chimaera or *chimère*, in architecture, is a term loosely used for any grotesque, fantastic or imaginary beast employed in decoration.

CHIMAY, a town in the extreme south-east of the province of Hainaut, Belgium, dating from the seventh century. Pop. (1925), 3,366. Owing to its proximity to the French frontier it has undergone many sieges, the last of which was in 1640, when Turenne reduced it to ruins. The town is chiefly famous for the castle and park that bear its name. Originally a stronghold of the Cröy family, it has passed through the D'Arenbergs to its present owners, the princes of Caraman-Chimay. The castle, which in

1640 possessed seven towers, has now only one, which is in ruins; a château was built in the Tudor style in the 18th century. This domain carried with it the right to one of the twelve peerages of Hainaut. The church contains a fine monument of Philippe de Cröy, chamberlain and comrade in arms of the emperor Charles V. John Froissart, the chronicler, died and was buried here, and has a statue in the square.

CHIME. (1) Probably derived from a mistaken separation into two words, *chimbe bell*, of *chymbal* or *chymbel*, the old form of "cymbal," Lat. *cymbalum*. A mechanical arrangement by which a set of bells in a church or other tower, or in a clock, are struck so as to produce a sequence of musical sounds or a tune. (For the mechanism of such an arrangement in a clock and in a set of bells, see the articles *CLOCK* and *BELL*.) (2) From Mid. Eng. *chimb*, a word meaning "edge," common in varied forms to Teutonic languages, cf. Ger. *Kimme*, the bevelled rim formed by the projecting staves at the ends of a cask.

CHIME-BELLS, a mediaeval instrument consisting of a set of small bells of varying pitch which were arranged in a frame and struck with a hammer after the manner of a glockenspiel. They ranged in number from four or five up to as many as 14 or 15. The chime-bells were known also under the Latin name of *cymbalum*.

CHIMERE, in modern English use the name of a garment worn as part of the ceremonial dress of Anglican bishops. It is a long sleeveless gown of silk or satin, open down the front, gathered in at the back between the shoulders, and with slits for the arms. It is worn over the rochet (*q.v.*), and its colour is either black or scarlet (convocation robes). The origin of the chimere has been the subject of much debate; but it is practically proved to be derived from the mediaeval tabard, an upper garment worn in civil life by all classes of people both in England and abroad. It has therefore a common origin with certain academic robes (see *ROBES*, *Academic dress*). The word "chimere," which first appears in England in the 14th century, is of uncertain origin. It occurs in different forms in various languages (Lat. *chimera*, Fr. *simarre*, Ital. *zimarra*) and may possibly be derived from the Greek *χείμερος*, "wintry". This derivation is made plausible by the original character of the chimere; for the word properly applies to the sleeveless tabard which tended to supersede, from the 15th century onwards, the inconvenient *cappa clausa* (a long closed cloak with a slit in front for the arms) as the out-of-doors upper garment of bishops. The chimere was, moreover, a cold weather garment. In summer its place was taken by the tippet. In the Anglican form for the consecration of bishops the newly consecrated prelate, hitherto vested in rochet, is directed to put on "the rest of the episcopal habit," i.e. the chimere. The robe has thus become in the Church of England symbolical of the episcopal office, and is in effect a liturgical vestment. The civil quality of the garment still survives; the full dress of an Anglican prelate at civil functions of importance (e.g. in parliament, or at court) is still rochet and chimere. The continental equivalent of the chimere is the *zimarra* or *simarre*, which is defined by foreign ecclesiologists as a kind of *soutane* (cassock), from which it is distinguished by having a small cape and short, open arms (*manches-fausse*) reaching to the middle of the upper arm and decorated with buttons. In France and Germany it is fitted more or less to the figure; in Italy it is wider and falls down straight in front. Like the *soutane*, the *zimarra* is not proper to any particular rank of clergy, but for bishops and prelates it is ornamented with red buttons and bindings. It is worn by university professors. A black *zimarra* lined with white, and sometimes ornamented with a white binding and gold tassels, is worn by the pope.

BIBLIOGRAPHY.—See the *Report* of the sub-committee of Convocation on the ornaments of the church and its ministers, p. 31 (London, 1908); the Rev. N. F. Robinson, "The black chimere of Anglican Prelates: a plea for its retention and proper use," in *Transactions of the St. Paul's Ecclesiological Soc.* vol. iv. pp. 181-220 (London, 1898); Herbert Druitt, *Costume on Brasses* (London, 1906); G. CHIMKENT, a town in the Syr Daria province of the Kazak (Kirghiz) A.S.S.R. of the R.S.F.S.R., Lat. 42° 20' N., Long. 69° 40' E. Pop. (1926) 21,708, mostly Sarts. It lies in a fertile valley between the Alexander range and the Ala-tau, and is the centre of a grain, fruit growing and cattle rearing district, watered by streams from the Ala-tau. Above the town are the ruins of its citadel, stormed by the Russians in 1864. Its clear, dry air makes it a health resort for tubercular patients taking the kumiss (fermented mare's milk) cure. Its industries include the preparation of santolin, cotton, tobacco, oil and flour.

The construction of a branch line from the Orenburg-Tashkent Railway through Chimkent to link up with the Trans-Siberian Railway at Semipalatinsk has already (1928) proceeded as far as Aulie-Ata, and should restore to Chimkent much of its former trading importance.

CHIMNEY, that portion of a building by means of which smoke is conveyed from fires inside to the outside air. The necessity of a chimney appears only when braziers are abandoned in favour of large fireplaces. Thus in northern Europe in the 12th century the primitive hole in the roof yielded to a hollow flue leading from a fireplace by the wall to the outside; but a specific architectural form of flue was not developed until the 15th century. The 13th and 14th century type was a simple, round, vertical conduit of stone, with a conical cap and openings at the sides under the cone. A remarkable example occurs in the monastic kitchen of the Abbey of Fontevault, France, dating from the end of the 12th century. In the early 15th century the re-duplication of fireplaces led to the grouping of several flues inside a vertical, and generally rectangular, mass of masonry, which was carried well above the roof, and occasionally decorated. In France, in the latter half of the century, this decoration was of great richness, consisting of late Gothic pinnacles and niches, and in the châteaux of the Francis I. period, chimneys vied with dormers in their lavish detail. Heraldic ornaments, pilasters and entablatures abound. In England, decorative effect was obtained by grouping the flue tops as independent features, usually in brick, above a stone base; each flue was then treated as a separate shaft with base and cap, polygonal or twisted; e.g., Compton Wynyates and Hampton Court palace. In the early Renaissance, the flues were sometimes treated like little classic columns, as at Burleigh House. With the development of classicism, the chimney became simple

again, a mere rectangular mass of masonry. In colonial work in America, the chimney is either a large square mass in the centre of the roof or else developed as an important feature of the end gable walls. In the Italian Renaissance the chimney is merely utilitarian and, whenever possible, is hidden. (T. F. H.)

CHIMNEY AND FIREPLACE CONSTRUCTION

Correct chimney construction is absolutely essential to economical home heating. The ideal and most efficient chimney is vertical, with round flue and smooth interior surfaces (fig. 1). All chim-

neys should be built with "fire-clay" flue linings (not "flue-tile," "terra-cotta" or "clay" flue lining). Faulty chimney construction practically always shows its shortcomings by its effect upon some other feature of the plant. A lighted paper thrust in the bottom and sucked up and consumed with a roar is often erroneously taken to indicate a good draught. Chimney draught can be known definitely only by measurement with the proper instrument, a

or direction of wind, the amount of moisture in the air or the quality of the fuel may aggravate the trouble. A smoke test will prove leaks and every flue should be tested before a boiler is connected thereto, by building a paper, straw, wood or tar-paper fire at the base of the flue. When the smoke is passing in dense volume

FIG. 1.—EXAMPLES OF CHIMNEY CONSTRUCTION. A. ROUND FLUE; B. SQUARE FLUE; C. OBLONG FLUE; D. ELONGATED OBLONG FLUE. TYPE A IS THE BEST, TYPE B, SECOND BEST, TYPE C, NEXT PREFERABLE, TYPE D, POOR CONSTRUCTION

draught gage. Chimney height and temperature inside and outside the chimney determine intensity of draught in a correctly built chimney.

Factors that contribute to faulty chimneys are: (1) Insufficient height to assure proper draught and avoid interfering air currents (fig. 2); the top of a chimney should extend at least 3ft. above flat roofs and at least 2ft. above the ridge of peaked roofs; extensions, if used, should be fitted with air-tight joints; (2) omission of flue-lining to ensure continued tightness, so that heat and weathering cause mortar gradually to disintegrate and result in a leaky chimney (fig. 2); (3) offsets and bends are likely to reduce the chimney free area and present difficulties in construction that militate against tightness and inside smoothness; loose bricks and mortar may fall and lodge in such a way as to cause objectionable restricted areas and provide lodgement for dangerous soot accumulations (fig. 2); (4) careless and improper installation of the smoke pipe into the chimney (fig. 3); (5) openings into a chimney for other than the smoke pipe of the boiler; such should never be permitted, they are apt to check and interfere with the draught; (6) lack of a tightly-fitting cover for the clean-out door; (7) failure to support the chimney properly; it should never be based on timber construction and when resting upon the ground sufficient masonry foundation should be provided to prevent settling; (8) improper laying of brick; it should never be laid on edge, should be properly bonded and sufficient mortar used between the bricks to fill all voids. Size and height of chimneys depend upon the total heat demands of the structure to be served, the type and number of boilers and the fuel to be used. Reputable manufacturers specify draught requirements for their respective equipment and state the required flue areas, sizes and heights of chimneys; these should be observed. Irrespective of fuel used, the minimum effective area¹ inside the flue lining for any installation should be not less than 70 sq.in. and the short cross-sectional dimension should be never less than six-tenths of the greater dimension. The minimum chimney height above the grate should be 35ft. if erratic draughts are to be avoided.

A chimney that is not tight will fail to draw properly. Force

¹Effective area of a flue, broadly speaking, is the theoretical cross-sectional area occupied by the column of smoke and gases rising with spiral motion up the flue.

FIG. 2.—EXAMPLES OF CHIMNEY CONSTRUCTION. A. TOP TOO LOW, EDDY CURRENTS CAUSE DOWN DRAFT; B. TOP CARRIED PROPER HEIGHT; C. UNLINED FLUE BEFORE USE; D. UNLINED FLUE, LEAKS CAUSED BY HOT GASES AND WEATHERING; E. LINED FLUE, A PREVENTION AGAINST LEAKS; F. OFFSETS TO BE AVOIDED

if the stack be tightly blocked by laying a wet blanket over it, the leakage will be immediately evident by the appearance of smoke at the opening, or from an adjoining flue indicating leakage between the flue joints.

If a leakage is not obviously evident, further inspection by means of a mirror held at the proper angle at the base of a straight flue should be made for minor obstructions such as broken tile, mortar accumulations, birds' nests, partly burned paper, soot or tarry deposits; or removal may be accomplished by passing up and down the flue a weighted bag of hay or straw attached to the end of two ropes.

Fireplaces.—A satisfactory open fireplace requires: (1) a flue of proper area, (2) fireplace throat correctly proportioned and located, (3) a correctly built smoke shelf and chamber, (4) sufficient chimney height, (5) a shape for radiating maximum heat into the room. The area of a lined flue should equal one-tenth or more of that of the fireplace opening. For unlined flues, the proportion should be increased due to greater friction. For lined flue,

FIG. 3.—EXAMPLES OF SMOKE-PIPE CONNECTIONS. A. INCORRECT, LEAKY JOINT; B. INCORRECT, PIPE PROJECTS TOO FAR INTO CHIMNEY; C. CORRECT, PIPE MEETS EDGE OF FLUE AND JOINT PROPERLY SEALED

allow 13 sq.in. of clear flue area to each square foot of fireplace opening. The cross-sectional area should be the same throughout the entire length of the chimney.

Correct throat construction is essential, to avoid a smoky fireplace and to provide for proper velocity of the outgoing gases. The area of the throat should be not less than that of the flue, its length always equal to the width of the fireplace opening (fig. 4); the sides of the fireplace should be vertical until the throat is passed (fig. 4); and above the throat, the sides should be drawn in until the desired flue area is obtained; the throat should be not more than 4 or 5 in. in width and set 8 in. above the lintel of the opening (fig. 4). The use of a throat damper is advisable; if omitted, the throat opening should be 4 in. and the smoke shelf

FIG. 4.—FAULTY AND CORRECT FIREPLACE CONSTRUCTION. A. TOP OF THROAT DAMPER IS AT DD, SMOKE SHELF AT CC. SIDE WALL SHOULD NOT BE DRAWN IN UNTIL THE HEIGHT DD IS PASSED. IF DRAWN IN AS INDICATED BY EF AND EG, THE WIDTH OF THROAT BECOMES LESS THAN THE WIDTH OF THE OPENING AND CAUSES THE AIR CURRENTS TO PILE UP RESULTING IN A SMOKY FIREPLACE. B. CORRECT FIREPLACE CONSTRUCTION

always included. A smoke shelf and chamber are absolutely essential. The shelf is formed by setting back the brick work at the top of the throat to the line of the flue wall, making the shelf equal in length to that of the throat. No shelf should be less than 4 in. and may vary from this to 12 in. or more, depending on depth of fireplace; the level of the shelf should be 8 in. above the fireplace opening (fig. 4). The smoke chamber acts as a reservoir to hold accumulated smoke temporarily when a gust of wind across the chimney top momentarily dampers the chimney, as well as to lessen the down draft and prevent smoke being forced

into the room. All smoke chamber walls should be smooth inside. The back of a fireplace should pitch forward from a point a little less than half-way from the hearth to the top of the opening and the sides should be beveled, as straight back and sides do not radiate heat as well.

The use of a throat damper affords means for regulating a fire. The type with lid hinged at rear, rather than in the centre, directs better the outgoing smoke into the flue. Full opening is required for fast-burning pine; slow-burning hardwood logs require only 1 or 2 in. openings. Fireplace openings should be kept low, 30 in. minimum and 42 in. maximum height. The higher the opening, the greater the possibility of a smoky fireplace; the width of opening should be slightly greater than the height; a minimum depth of 18 in. is advisable although 12 in., in small fireplaces, will provide a good draft with properly constructed throat.

Efficiency of fireplace heating can be improved materially by the use of a fireplace heater which heats all incoming air before it enters the room. These devices consist of an intake air manifold, into which air from the outside is drawn and delivered into heat pipes lining the rear wall of the fireplace, from which it passes into a heated air manifold and is then delivered into the room directly above the fireplace openings at temperatures varying from 135° to 195° F. Tests have shown that the use of a proper fireplace heater is the means of increasing measurably the effectiveness of fireplace heating, through, (1) raising the room temperature $3\frac{1}{4}$ times as quickly as can be done with the bare fireplace, (2) maintaining a far more even temperature throughout the entire room, (3) avoiding cold air leakage through window and door cracks and (4) by producing a greater heating effect with less fuel than when no heater is used. (A. M. D.)

See J. J. Norman, *Design of a Brick Chimney* (1913); J. G. Mingle, *Draft and Capacity of Chimneys* (1925); A. Custodis, *Radical Brick Chimneys* (1924).

CHIMNEY-PIECE, in architecture, originally a hood, projecting from the wall over a grate, built to catch the smoke and lead it up to the chimney flue; later, any decorative development of the same type or for the same purpose; a mantel or mantel-piece. Like the chimney (*q.v.*), the chimney-piece is essentially a northern mediaeval development. Its earliest form, a simple hood, sometimes with shafts below, at the wall, is shown in the king's house at Southampton and at Rochester castle, England (12th century). Later, the spaces under the ends of the hood were made solid, so that the fireplace became a rectangular opening, and in some cases the fireplace was recessed into the wall. Late mediaeval fireplaces are of great size and richness, e.g. the triple fireplace in the great hall of the Palais des Comtes at Poitiers, and the earlier fireplaces in the château of Blois.

During the Renaissance fireplace openings were decorated with columns, pilasters and entablatures, and occasionally the front of the wall or hood above the overmantel was enriched. North Italian palaces are full of examples of great delicacy. In France the fireplaces at Blois and Chambord are famous. In England, the same formula appears in naïve and complex types, with the usual Elizabethan and Jacobean *mélange* of misunderstood classic and Flemish motives—strap work, gaines, etc. In France, after a brief classicism under Henry II. and Henry IV., the chimney-piece became a centre of fantastic design. Although the opening was usually small, the decoration was rich, and commonly characterized by the use of a great mirror as an overmantel. The detail assumed the classic extravagance of the Louis XIV. style, the swelling curves and bulbous shells of the Louis XV. and the distinguished restraint of the Louis XVI. styles, but almost always retained the same general proportions and the mirror. German design largely followed that of France; chimney-pieces are less numerous there, however, owing to the use of porcelain stoves.

In England the Renaissance chimney-piece was at first treated, with simple architraves, frieze and cornice, in such a way as to serve as mantel shelf, occasionally with rich panelling above, and much breaking or keying of the mouldings. Later, consoles, caryatides and columns were used, although occasionally a simple moulding of sweeping profile replaced the architrave, and the shelf was omitted. In the last half of the 18th century the char-

MODERN ENGLISH CHIMNEY PIECE BY COURTESY OF "THE AMERICAN ARCHITECT"

CHIMNEY-PIECES FROM THE 15TH TO THE 20TH CENTURIES

The early fireplaces of the Gothic period were enormous in order to permit the burning of large logs, but the manner in which they smoked led to a continued decrease in size, which reached a climax in modern English chimney-pieces designed for burning coal. The projection of the chimney breast has always been realized as a decorative opportunity and was developed in nearly all the Renaissance styles

acteristic English chimney-pieces, in the style of Robert Adam, owed much to Louis XVI. influence. In American colonial work, there is an almost exact following of English precedent, and occasional examples can be traced to definite plates in English architectural books.

CHIMPANZEE, the popular name (of native African origin) of the more widely distributed of the two genera of anthropoid apes of the African equatorial forests; the other being the closely related but larger gorilla (*q.v.*). The paramount interest of the chimpanzee lies in its resemblance to man. Though it walks on all fours, is covered with abundant hair and has a grasping hand-like foot, its zoological affinities are with man rather than with the tailed monkeys as abundantly attested by comparative anatomy, physiology and bio-chemistry. The chimpanzee is a forest dweller, associating in small bands, spending a large part of the time in trees where it constructs rude sleeping nests and feeds on fruits and other vegetable matter. It is easily distinguished from the other great apes by its flesh-coloured skin which, however, grows darker with age and by its large outstanding ears. The prevailing colour of the hair is black. An adult male may weigh 160 lb. and standing erect may be 4½ ft. in height.

The popular reputation of this ape for superior intelligence has been amply confirmed by elaborate experimental studies of its mentality by the psychologists W. Koehler and R. M. Yerkes. The results obtained indicate that the chimpanzee mind is more man-like than monkey-like in the mode of its operations, though in content or range it stands closer to the monkeys. The lack of capacity for speech seems absolutely to preclude the attainment of any culture or social inheritance.

The nomenclature of the chimpanzee is in a very unsettled state, chiefly owing to confusion with the orang-utan by earlier writers. The generic names which have had the widest currency are *Anthropopithecus* and *Troglodytes*, but the rules of nomenclature seem to indicate that the Linnaean name *Simia satyrus* (generally applied to the orang-utan) belongs rightfully to the chimpanzee. Several local variants have been described as species, but it seems probable that most of them are mere local varieties of one or, at most, two or three valid species (*see PRIMATES*).

CHIN, a Burmese term for a hill-man applied in particular to branches of the Kuki (*q.v.*) race, inhabiting the hills along the west bank of the Chindwin river south of Manipur.

CHINA, a vast country of Eastern Asia, the scene of the oldest contemporary civilization and the world's largest cultural unit. The official name is Chung-Hua Min-Kuo, *i.e.*, Republic of China.

See CHINESE ARCHITECTURE, CHINESE LITERATURE etc. The territory of China now comprises:

(a) **China Proper** with 21 provinces. Of these the three Manchurian provinces (Fengtien, Kirin and Heilungkiang), administered as a single entity were only incorporated in China Proper in 1907, and even under the Republic have distinct organization and development.

(b) **Mongolia**.—The term Mongolia, as used to denote a political or even a cultural entity, is now very misleading. There is a vital distinction between Outer and Inner Mongolia. *Outer Mongolia*, still essentially Mongol in race and character, is autonomous, with its own centre of government at Urga, and has asserted its independence. Its orientation is to the Trans-Siberian railway and the Union of Socialist Soviet Republics; but China has not relinquished its claims, and the Sino-Soviet Treaty of 1924 recognized that "Outer Mongolia" is an integral part of the Republic of China and respects China's sovereignty therein." Its precise international status must be regarded as still uncertain. *Inner Mongolia*, on the other hand, is becoming more and more linked with China. The area comprised within it, together with portions of the adjacent provinces of Chihli and Shansi, has been divided into three provisional provinces (Jehol, Chahar and Suiyuan) increasingly Chinese in character, and a special administrative district (Sitao), attached to Kansu province.

(c) **Sinkiang**, or the New Dominion, consisting of Chinese or

eastern Turkestan, Kulja and Kashgaria, *i.e.*, virtually the area between Outer Mongolia on the north and Tibet and Kashmir on the south. It is mainly inhabited by non-Chinese peoples but administered by Chinese officials. Connected with Sinkiang is the Altai administrative area, controlling the passes through the Altai mountains into Turkistan from Outer Mongolia.

(d) **Tibet**.—No more than Mongolia can Tibet be considered as a single political or administrative unit. The term in a political

A SMALL WAYSIDE SHRINE BUILT ON THE CHINA-TIBET FRONTIER

sense is now applicable only to that south-western portion of the country which is under the Lhasa Government, and whose relationship to China is like that of Outer Mongolia. Great Britain and Russia (1907) agreed to negotiate with Tibet only through China, and Chinese sovereignty is technically maintained. But the Lhasa Government is virtually independent and has closer relations with British India than with China. On the other hand China has actively asserted her interests in those peripheral portions of Tibet which can menace either China Proper or the vital corridor leading by way of Kansu province to Sinkiang and the Pamir passes. To protect China's interests on the Tibetan border two important administrative divisions under direct Chinese rule have recently been formed. 1. *Sikang* (Szechwan Marches) or *Chwanpien*, with Baifu (Batang) as its capital, formed by uniting eastern Tibet with the western mountainous part of Szechwan. This acts as a buffer between Tibet Proper and the Red basin of Szechwan. 2. *Tsinghai* or *Kokonor* embracing the Kokonor depression and the Nanshan mountains, the north-eastern ramparts of the Tibetan plateau, similarly protects the Kansu-Tarim corridor and presses back the Chinese frontier into what physically and racially is Tibet.

Stated in physical terms, the essential China consists of the middle and lower basins of the Hwang-ho, Yangtze Kiang and Si-kiang to the east of the high buttresses of the Tibetan and Mongolian plateaux. The Manchurian plain marks the continuation of the monsoon-watered lowlands beyond the sea-ward end of the Great Wall which delimited the original Chinese culture area. The three districts of Inner Mongolia denote the more fertile southern and eastern margins of the Desert of Gobi, open to colonization from China and Manchuria. The distant Sinkiang occupies the deep Tarim depression between the Kunlun, the lofty northern buttress of the Tibetan plateau, and the Tien Shan. Where these great chains converge in the mountain-knot of Kashgaria and the Pamirs occur the famous passes, which through all history have connected China with the West by routes following the northern and southern margins of the depression to Kashgar and Yarkand. The Tien Shan mountains and the grasslands of the Jungarian gate between them and the Altai, are also included within Sinkiang province which derives its main significance in relation to the land communications of China. The oasis-studded margins of the Tarim depression and the rich grasslands of Jungaria give it also agricultural importance.

Thus the outlying "dependencies" still held by China are very closely related geographically to the main scene of Chinese civiliza-

tion and are vital factors in her future, for colonization and communications. In contrast, Tibet, in the more restricted sense, and Outer Mongolia, now virtually lost, are geographically remote. The isolation and inaccessibility of Tibet are notorious. Outer Mongolia occupies the steppe zone and the forest border to the north of the broad Desert of Gobi and so turns its back on China.

The Chinese dominion in the widest acceptance of the term, including those parts of Mongolia and Tibet which are only technically subject to Chinese sovereignty, occupies an area estimated at 4,277,260 square miles. It is made up as follows:—

| | |
|--|-----------|
| China Proper (excluding Manchuria) | 1,532,420 |
| Manchuria | 363,700 |
| Mongolia | 1,367,600 |
| Sinkiang | 550,340 |
| Tibet | 463,000 |
| Provinces of Hwang-ho Basin | 522,260 |
| Provinces of Yang-tze Basin (including Chekiang) | 572,830 |
| Provinces of Sikiang Basin (including Fukien) | 437,330 |

Further important administrative changes were made in 1928. The three Inner Mongolian divisions of Jehol, Chahar and Suizuan have been given definite provincial status, and a further portion of northern Chihli (now known as Hopeh) has been incorporated with Chahar. Moreover, the military territory of Sitao together with the north-eastern part of Kansu has been constituted a province, called Ningsia. Tsinghai (Kokonor) and Sikang (Chwantsien) have also acquired the status of provinces.

I. THE COUNTRY

The immense terrain indicated in the preceding section is infinitely diverse. Even within China Proper there is great variety of structure, climate and vegetation.

THE GROUND PLAN

It is to middle and south-eastern China that the description of China as a land of river-valleys is most applicable. There the Yang-tze Kiang and Si-kiang occupy well-defined valleys, each of which is the focus of the population and of the activity of the basin and still serves as the principal artery of commerce within it. In contrast the Hwang-ho, the great river of the north, has no such well-defined valley. In its upper course it hurries through deep trenches and in its lower course it wanders over the wide open plain in a channel liable to shift bodily for hundreds of miles. Thus the Hwang-ho is clearly not the arterial line of north China as the Yang-tze is of middle China, and, in the absence of any such unifying influence, the natural division of the north is into the great plains of its eastern and the loess-covered plateaux of its western sections. Thus the initial distinction to be made is between the plains and loess-covered uplands which make up north China and the mountain and valley country of middle and south China. Between the two interpose, in the west, the high ranges of the Tsin-ling-shan, an eastern extension of the Kunlun and the sharpest climatic and vegetational divide in the whole of China. Eastwards the Tsin-ling ranges sink into the Fu-niu-shan and then the Hwai-yang-shan.

The loess-covered uplands of north-west China form a broad belt from Jehol to Kansu keeping north of the Tsin-ling divide. Loess, it is true, extends down from the uplands into the western margins of the north China plain, but it here lies too low to affect the topography in the same distinctive way as in the uplands, the loess-lands proper. These take the form of a girdle around Mongolia, a high rolling tableland, in places swept clean of any rock detritus, but in others piled high with sand-dunes, the most probable source of the wind-borne loess of north-west China. The loess mantle, leaving only the ridges exposed, yet with a thickness of rarely more than 200 ft., weathers because of a strongly developed vertical cleavage into a topography of cliff-edges and steep-sided terraces. The same vertical cleavage is responsible for the porosity of the loess which, while accentuating the dryness of the plateau surface, gives rise to a relative abundance of water in the numerous basins within it. The loess is, however, no more than a mantle cast over a pattern of relief independent of it.

The northern part of the belt consists of a parallel series of high broad-backed ridges separated by equally broad loess-filled

troughs, the whole trending from north-east to south-west athwart the routes between the north China plain and the Mongolian plateau. The route between Peking and Kalgan, the gateway into Mongolia, utilizes, however, the transverse valley of the Hun-ho and the easy Nankou pass. Southwards the ridges gradually sink beneath the plateau of south Shansi whose south-eastern part constitutes a coalfield of the size of Wales. Let down beneath the general surface of this plateau is a chain of exceedingly fertile loess basins stretching from Tai-yüan in the north by way of the Fenhö to the Wei-ho valley in Shensi. Leading from the plain into west China, this chain of basins was followed by the Imperial Courier road from Peking to the western province of Szechwan and from the establishment of Peking as capital until the advent of the railway, it was this rather than the Hwang-ho which formed the main artery of commerce in the southern loess-lands. The loess belt as a whole constitutes one of the most distinctive regions in all China and was the cradle-land of Chinese civilization.

The North China Plain.—The second major division of north China is the great plain which in the north communicates by a narrow lowland corridor with the plains of Manchuria and in the south-east merges imperceptibly with the delta of the Yang-tze. Rising partly out of the plain and partly out of the Yellow sea, on which the plain is steadily encroaching, are the broken uplands of Shantung. The Hwang-ho has passed at certain periods to the south and at others to the north of them. The drainage of the plain is, however, to a large extent independent of the Hwang-ho, the streams of the northern portion finding their outlet by the Hai-ho at Tientsin and of the southern by the Hwai-ho, much of whose basin was for long a vast swamp. Shifting of channels has spread river sand and gravel, and the plain is not so continuously fertile as the deltaic alluvium of the Lower Yang-tze.

The Shantung uplands are divided into two masses by a broad lowland now followed by the Shantung railway from Kiaochow bay. The eastern peninsular half faces the very similar peninsula of Liaotung. Both lie athwart the seaward approaches to the plains of Chihli and of Manchuria and their well-articulated coasts offer the best harbours in north China.

Thus in north China the loess and the plain give considerable uniformity of surface conditions and have always been in close relationship. In south and middle China mountain ridge and valley succeed each other apparently without end. The only large tableland is that of Yunnan in the south-west. The largest plains are simply expanded valley-basins and nowhere approach the bulk of the north China plain. Again, there is nothing to parallel the superficial uniformity bestowed on north-west China by the loess mantle. If the key-note of the surface of north China be uniformity, that of middle and south China is variety.

South China Highlands.—To the rugged dissected massif south of the Yang-tze the term South China Highlands is often applied. In the east high axial ranges overlook the broken country of the coastal provinces (Chekiang, Fukien and Kwangtung). In the west and south-west the characteristic form is that of massive and lofty plateaux. The intermediate country of south-central China is in the nature of a saddle between the eastern scarps and the western tableland, and across it the main routes from the Yang-tze valley pass to that of the Si-kiang. The approach from the Yang-tze is by way of the Siang and Kan valleys leading up to the Che-ling and Mei-ling passes respectively, the routes from both of which converge to pass down the Pei-kiang valley to the delta of the Si-kiang.

The Central Asian background of middle and south China is not the Mongolian plateau but high mountain ranges trending from north to south, the eastern border of the Tibetan highlands and the "march-lands" of Szechwan. These ranges confine the drainage in parallel longitudinal channels and of the great rivers which flow southwards from Tibet only the Yang-tze, by means of a complex series of gorges, escapes to the east. After this torrential descent from the Tibetan highlands the Yang-tze enters on the Red basin of Szechwan, the first of the chain of basins characterizing its later course. But, unlike those farther downstream, the Red basin is an upland basin so vigorously dissected into hilly country that the only plain of any extent, that of Chengtu at the

foot of the high ranges of Szechwan Marches, is due to quite special causes. The basin, almost completely ringed round by high mountain country, is a region apart, communicating with the rest of China mainly by way of the difficult route of the Yang-tze gorges cut through the mountain rim. Below the gorges the Yang-tze begins its true valley course. It is aligned alternately to the north-east when it is broad and open and to the south-east when it is confined and almost gorge-like, as it cuts through the north-east-south-west ridges of the eastern part of the south China highlands. In this valley course the Yang-tze first flows through the lowland alluvium-covered basin of Hupeh, on which converge the important river valleys of the Han from the north-west, the Yang-tze from the west, the Yuen and Siang from the south-west and south. The routes from north to south China, soon to be crystallized in the Peking-Hankow-Canton railway, here cross the west-to-east arterial route of the Yang-tze valley. This is pre-eminently the central basin of China. Below it the Yang-tze, though passing through several small basins as that of Wuhu and skirting the margin of the larger Po-yang basin of Kiangsi, does not itself flow through a basin of comparable size until its delta begins at Nanking. The delta is in the nature of an incompletely filled basin (the Chusan archipelago marks part of its eastern rim), but it is advancing seawards at the rate of one mile in every 60 years. As the Yang-tze has at this stage deposited all its coarser detritus, the delta consists much more uniformly of fertile silt than the central basin farther upstream.

South China.—The Si-kiang of south China has a facies very different from that of the Yang-tze. It has a normal valley course, without basins, through the south China highlands until it finally broadens out to form its delta. Its upper valley is entrenched in the south-easterly prolongations of the Yunnan-Kweichow plateau but its lower cuts through the scarped country of south-east China. The routes linking the Si-kiang with the rest of China, whether by land over the saddle between the south-eastern ranges and the south-western plateau, or by sea, all lead from Canton, the unmistakable focus of south China. The orientation of Canton, separated from the central Yang-tze basin by the whole breadth of the south China highlands and looking out over the sea towards the Indies, strongly contrasts with that of the north, encompassed by steppes and deserts. (See CANTON.)

The maritime provinces of south-east China, between the Canton and Yang-tze deltas, form a very distinct region dominated by the south-west-north-east ridges which culminate westwards in the high axial range of the Ta-sha-ling on the Fukien-Kiangsi border, the watershed between the Yang-tze drainage and the basins of several relatively small coastal streams.

This highly diversified region communicates with the rest of China more naturally by sea than by the difficult interior mountain passes. It is a little world apart, with a distinctive set of space-relations. (See FUKIEN.)

The deeply dissected plateau of south-west China stands apart from the scheme of river-basins here outlined, and as an immense watershed, forms another distinct entity. In Kweichow the plateau is lowest and most dissected by winding river courses, but it rises towards the west and in eastern Yunnan the rolling surface of the tableland is broken only by deeply trenched valleys and sunken lake basins. Farther west the trenches become deeper and the tableland between them narrower until, in western Yunnan the plateau disappears and there is left a succession of high, narrow north-south ranges and very deep river troughs, belonging to the system of parallel chains and troughs of west Indo-China. The approaches to the south-west plateau from the heart of China are tortuous enough, but these north-south ranges and troughs of West Yunnan make it almost inaccessible from the west. Hence its orientation is towards China with which it has been gradually incorporated, but it was the latest part of the country to be colonized.

Mineral Resources.—Coal measures of workable bulk occur at two geological horizons—the Permo-Carboniferous and the Rhaetic-Lias; the coals of the latter are commonly more friable and of generally poorer quality than those of the Permo-Carboniferous. There is an important difference, too, in their

distribution. The Permo-Carboniferous occur mainly in north, the Rhaetic-Lias mainly in south China. In both north and south China the larger fields lie towards the west, so that even the smaller fields near the sea have considerable significance.

The Permo-Carboniferous plateau of south-east Shansi forms by far the greatest Chinese coalfield; continued, in more broken form, on either side in the troughs of south-west Shansi and in the faulted blocks at the foot of the Tai-hang-shan. Coastal position gives significance to the small fields of Fushun in south Manchuria, Kaiping in Chihli, and, though less important, Poshan and Ihsien in Shantung. In south China the most accessible and most valuable fields lie in the Siang valley along the corridor route from the central basin to the Canton delta. These are of Permian and, at Pinghsiang, of Rhaetic age. In the west the Rhaetic coal measures cover immense areas in the plateau of Kweichow and west Kwangsi and underlie most of the Red basin of Szechwan. Their coals are, however, very friable, especially those of Szechwan. Many synclinal troughs of south-east China contain Permo-Carboniferous coal measures which owe their significance to their proximity to the coast.

In the distribution of metallic ores there are again real differences between north and south. In north China and in the lower Yang-tze valley iron is almost the only metallic ore of importance, but in south China there is a great variety of ores including tin, copper, lead, zinc, antimony, tungsten, manganese and mercury as well as iron. Of the iron ores four main types occur. Interbedded with both Permo-Carboniferous and Rhaetic-Lias coal measures are nodules and lenses of carbonate ores which must comprise an enormous reserve but occur under conditions unsuited to modern mining. The Archaean ores in the Liaotung massif of south Manchuria are similar in nature to those of the Lake Superior ranges though of lower grade. Scattered over north China but especially abundant along the line of the Lower Yang-tze, just outside the Sinian môle, there have been developed numerous magnetite-haematite iron ore bodies wherever granodiorite is intrusive into limestone. Although limited, they are important in the iron industry of the Far East owing to accessibility from the Yang-tze. About equal in bulk to these contact deposits along the Yang-tze are the oolitic haematites bedded in the pre-Cambrian of the "grill of Peking." Most of the larger deposits of other ores are concentrated into two areas: the first around the Nan-ling mountains on the border of Hunan with Kwangsi and Kwangtung and in upper Hunan; the second, in eastern Yunnan and adjoining parts of Szechwan and Kweichow. The Nan-ling is the centre of a number of tin-fields as yet largely unworked. Northwards the tin is replaced by the lead-zinc ores of Shui-kou-shan in the upper Siang valley, which in turn give way to the antimony of central Hunan. In Yunnan the tin also lies in the south, near Mengt'z, and the lead-zinc farther north in north-east Yunnan with Tungchwan as the centre. Even more important, however, in this region is copper. Yunnan indeed with its tin, lead-zinc and copper is the most important mineral region in China for ores other than iron.

CLIMATE

China has the essential monsoonal characteristic of a seasonal reversal of wind and a corresponding sharply marked seasonal differentiation of rainfall. The northerly outflowing winds of winter give its dry season, the southerly inflowing winds of summer its season of rains. Unlike India, hemmed in by the Himalayas, China is open to Central Asia by way of Mongolia from which strong and very cold winds sweep down in winter. So, too, in summer, China, unlike India, is not the single objective of the air circulation of a whole ocean and its monsoon consequently yields a less heavy and less concentrated rainfall spread much more equally over the interior. China, moreover, is a warm temperate rather than a tropical land, only its extreme southern fringes lying to the south of Cancer.

The winter monsoon sweeps over China from the north-west, but southwards it becomes first northerly in the Yang-tze delta and then, combining with winds blowing off the sea, north-easterly along the south China coast. North China experiences the north-

westerly and the south China coast the north-easterly régime during the whole winter monsoon (September to March). The intermediate Yang-tze delta is affected by the land-winds only from October to February; in September and again in March the prevailing winds are north-easterly from off the China seas. Between the winter and the summer monsoon comes a transitional period of calms (April and May) with light southerly breezes. The true south-east monsoon, never as strong as the north-west monsoon of winter, blows from June until August and, sweeping in from the sea, gives all China the bulk of its rainfall and also a striking uniformity of temperature, in strong contrast to the great regional variation in winter. Only locally, as in the Formosa channel, does the wind drift become south-west.

Exposed to the full blast of the north-westerlies from Central Asia, north China experiences exceptionally severe winters, the coldest in the world for its latitude (on the basis of temperatures reduced to sea-level). On latitude 40° N., Peking has an average January temperature of 23.5° F, St. Louis of 31.0° F and Naples of 46.8° F. The whole of China north of the Hwai river has at least one month whose mean temperature is below freezing-point. The Yang-tze valley is warmer, with temperatures in the depth of winter more like those of Britain, although the winter itself is much shorter. Yet the lake expanses of Tung-ting and Po-yang in the Yang-tze valley, in flood after the summer rains, are at times frozen over. South China has definitely warm winters, those of Hongkong being as warm as an English midsummer, although snow has been known in Canton. The winter, even in north China, is comparatively short and spring is nowhere long delayed. Summer uniformity is such that the midsummer temperature of Peking approaches to within 3° F of that of Hongkong (71.7°). The high temperatures are, however, much less prolonged in the north. It is agriculturally important that south China has temperatures of over 60° F practically throughout the year, the Yang-tze for six to seven months, and north China for five months. The Yang-tze valley has a "temperate" climate with neither the extremes of north China nor the uniformly high temperatures of the south, and this feature is most pronounced in the sheltered Red basin of Szechwan which, although far in the interior, has milder winters and cooler summers than the valley below the Gorges. (See SZECHWAN.) South-east China, ridged more or less at right angles to the monsoonal current, receives as a whole (the Fukien coast excepted) a higher annual rainfall—about 60 in.—than the plateaux of south-west China and the basin of Szechwan far in the interior, with about 40 inches. The average rainfall for the basins of the lower Yang-tze is slightly higher. The summer rainfall of southern China seems to be evenly distributed, save for exceptional precipitation on the southern coastal strip. High relief in south-west China counter-balances its interior situation, and so promotes this relative uniformity. North China, on the other hand, has a comparatively low relief and is a greater distance from the source of moisture. Hence while the Yang-tze delta has about 45 in., the plain to the north of the Hwai river receives from 20 to 30 and the loess plateau of north-west China less than 20; the rains die away altogether as the Gobi desert is approached.

Taking China as a whole, the rainfall is heaviest in the season of the south-east monsoon and least at the height of the north-west monsoon in mid-winter. Peking, as typical of north China, receives 75% of its precipitation during the summer months. But only 41% of the total fall of Shanghai occurs in that season. The Yang-tze Valley in winter receives occasional cyclones which draw in air from the south and from the sea on their southern flanks. These southerly winds temporarily replace the winter monsoon and bring rain. On the hilly coastlands of Chekiang and Fukien further precipitation occurs from condensation of moisture brought by the north-east monsoon. Thus the Yang-tze valley and the coastal provinces of the south-east have a more evenly distributed rainfall than any other part of China. (For climatic regions see below, *Natural Divisions of China*.)

VEGETATION

It is very difficult to reconstruct the primitive vegetation for

the face of nature has been greatly changed by long and intensive cultivation, and woods particularly have been destroyed. From the evidence of what remains, the natural vegetation of by far the greater part of China must have been woodland of peculiar richness and variety. The climate favours profusion of growth and the complex topography, especially of the south China highlands, where temperate and sub-tropical forms "dovetail" into each other, induces great variety of species. China has some 9,000 flowering plants, about half endemic, mainly in the valleys of the south-west. The Chinese flora, in fact, represents the overlap of the Indo-Malayan, the Palaearctic of the north European and Siberian plains and the Himalayan. The flora so compounded escaped any extensive impoverishment during the Ice age. In both North America and China plant-forms could migrate southwards more freely before the ice-sheets than in Europe, where they were crushed between the Scandinavian and Alpine ice and destroyed. The genera *Magnolia*, *Liriodendron*, *Menispermum* and *Nyssa* survive in both China and North America, though represented by different species, but they have been exterminated altogether in Europe.

The marked climatic rhythm of north China, which induces luxuriance of growth in summer but eliminates all but the hardier plants in winter, produces the supreme expression of the cool temperate, broad-leaved deciduous forest. The dominant trees, however, are not oaks and beeches, but more southern forms as the paulownia, catalpa and broussonetia, the paper-tree. But in north China the woodland covering must always have been scantier and less continuous than in any other region: in the loesslands only the better-watered ranges can have been forested and the north China plain probably consisted as much of heath and marsh as of forest. In the Yang-tze valley the milder and rainier winter imposes no such check on plant-life and broad-leaved evergreens replace deciduous trees. But deciduous and coniferous woods, though of a southern type, persist on the higher ranges and sub-tropical trees like camphor-wood, the tea-tree and the bamboo creep up the river valleys. The bamboo, which serves an enormous number of purposes, is, unlike any other, a cultivated tree, grown in groves throughout China south of the Tsinling. The variety of plant-life, typical of China as a whole, reaches its highest development in the Yang-tze valley and the south. Certain tropical forms, e.g., the tall palm and banana, are typical only of the lowlands of Kwangtung and Hainan, while others, e.g., the banyan tree, do not penetrate beyond the northern waterparting of the Si-kiang. The tropical forest of the valleys gives way on the lofty plateau of south-west China to grasses and shrubs, including many rhododendrons and trees and herbs of common European genera.

Even in the south China highlands de-forestation, though not so complete as in north China, has restricted the forests to the less accessible mountain slopes, long the refuge of pre-Chinese tribes; the more extensive are along the eastern edges of the Kweichow plateau and the axial ranges of the Fukien-Kiangsi border. They are made up of both deciduous (oak and chestnut) and coniferous trees (cunninghamia fir and sub-tropical pines). These woods supply timber to south China and the Yang-tze valley, while north China is dependent on the forests of the east Manchurian highlands. Throughout China there is urgent need for re-afforestation.

ANIMAL LIFE

Profusion of vegetation and variety of relief have fostered the development of a fauna of great diversity and have permitted the survival of animals elsewhere extinct. The diversity of the animal life is greatest in the ranges and valleys of remote western China and here mainly occur the forms peculiar to the country. Among these are the panda or cat-bear of the Tibetan border, the takin or goat-antelope of the Tsin-ling country, numerous species of pheasants and laughing thrushes, the little Yang-tze alligator (the only surviving alligator of the Old World), the giant salamander of central and south China, and several members of the carp family for which China seems to have been one of the chief centres of dispersal. The faunistic provinces are much less clearly defined than the botanical. While

in north China the steppe animals have Central Asian and the forest animals Siberian affinities, and into south China, Indian and Malayan forms have penetrated, in the Yang-tze valley a Palaearctic fauna persists on the mountain ranges, but the valleys between harbour the tropical oriental fauna. Although Palaearctic, the animal life of these ranges is Himalayan in its affinities whereas that of north China is Mongolian and Siberian. The Tsin-ling make a sharp divide between the forms inhabiting cool temperate and warm temperate latitudes in fauna as well as in flora. Owing to this overlap, increased by interpenetration of ranges and valleys, the Yang-tze valley has a varied fauna as well as a rich vegetation.

Summary.—From the data discussed under the previous headings it is possible to summarize the essential characteristics of each of the great natural divisions into which China falls from the standpoint of physical geography. Such a synthetic view is extremely helpful to the understanding of the human and economic conditions discussed in later sections: Manchuria and Inner Mongolia which lie beyond the Great Wall, the historic frontier of China Proper, are excluded from this summary.

I. North China.—A very distinctive major division. *Natural limits:* On the north-west and north the belt of scarps separating the northern apex of the plain from the rolling but relatively level Mongolian plateau. The outermost scarps, followed by the Great Wall, constitute a marked boundary. On the south-west and south the Tsin-ling-shan continued by the Funiu-shan and Hwai-yang-shan, forming the most decisive climatic, vegetational and economic divide in all China. To the south-east no clear delimitation, but historically the Hwai marshes were a great barrier.

Provinces within this natural division: Chih-li (Hopeh), Shantung, Shansi, most of Shensi and Honan, northern An-hwei, northern Kiangsu.

Essential characteristics: Light and mainly fertile soils, chiefly loess and alluvium: Cold, severe and dry winters with strong winds, often bringing dust storms from the north-west. Summers hot with a somewhat short rainy season; rainfall normally sufficient for agriculture but liable to fail. Rivers of little use for navigation (hence transport mainly by mule- or horse-drawn vehicles on sandy roads) and peculiarly liable to flood. Agriculture largely suspended in winter and precarious because of drought and flood. Famines common. Natural vegetation and cultivated products mainly "temperate." Essentially treeless.

Orientation of Region: Open historically to the mass movements of nomadic hordes from both Mongolia and Manchuria.

Chief sub-regions within the major division: loess plateau and associated basins, alluvial plain, Shantung highlands.

II. The Basin of the Lower Yang-tze.—*Natural Limits:* On the north the Tsin-ling-shan and its easterly continuations; on the south the Nan-shan (or Nan-ling), the divide between the Yang-tze and the Sikiang, and on the south-east the series of ranges known collectively as the Tayu-shan, the divide between the Yang-tze and the independent coast streams. On the west the Yang-tze gorges above Ichang.

Provinces included within this natural division: Hupeh and adjacent portions of south Shensi and south-west Honan, southern An-Hwei, southern Kiang-su with the northern fringe of Che-kiang, Kiang-si and Hunan.

Essential characteristics: Rich alluvial basins and valleys, separated by broken, hilly country, still in part forested. Winters mild to cool, with some cyclonic rains. Summers hot and wet. Meeting-ground of temperate and sub-tropical species, pines, chestnuts, maples on the one hand and some palms, camphor-woods, etc., on the other. Basis for a very wide range of cultivated products, northern cereals in winter, rice, cotton and tea in summer. Agricultural activity continuous throughout the year. A magnificent system of natural waterways.

Orientation of Region: The heart of China and the region most in touch with all other parts of the country.

Sub-regions within the major division: Numerous, the two most important being the Yang-tze delta and the Central (Hupeh) basin.

III. The Red Basin of Szechwan.—*Natural Limits:* Clearly

defined on all sides by lofty mountain chains. (Tapa-shan on north and north-east, Szechwanese Alps on north-west, west and south-west) or high plateau edge (Kweichow plateau on south) and steep scarps (south-east Szechwan).

Provinces included within this natural division: The whole of Szechwan save its high mountainous margins.

Essential characteristics: A large upland basin of red sandstone, dissected by river action into uplands and broad valleys whose sides lend themselves to extensive terracing. Climatic conditions similar to those of the lower Yang-tze, but with marked tendency to fog and cloudiness and very equable temperature régime. Rainfall assured. Famines due to drought or flood rare. Vegetation shows admixture of Himalayan forms. Range and character of cultivated products similar to those of Lower Yang-tze.

Orientation of Region: Isolated and self-contained. Slight and difficult contact with the rest of China by the Yang-tze gorges. The chief supply-base for eastern Tibet.

IV. South-east China.—*Natural limits:* The southern watershed of the Yang-tze, as defined above, on the north, the high edge of the Kweichow plateau on the west and the south China sea on the south and south-east.

Provinces included within this natural division: The maritime provinces of Che-kiang (except northern fringe), Fukien and Kwangtung together with Lower Kwangsi.

Essential characteristics: A core of very ancient rocks, crumpled into prominent ridges trending south-west-north-east; a sea of mountains, valleys and small basins. A long, faulted coastline, highly articulated, with many independent rivers, mostly unnavigable save in their lower courses. Topography fosters existence of many separate economic nuclei and great variety of dialects. Rainfall high and dry season short. Climate sub-tropical to tropical in the basins and lower valleys, permitting of two or more rice-crops, but winters in the highlands relatively cool.

Orientation of Region: Essentially maritime; close connections with Indo-China and Malaya; communications with rest of China on landward side very difficult.

Sub-regions: Numerous, including Canton delta and lower Si-kiang valley, Swatow, Amoy and Foochow valley basins.

V. South-west China.—*Natural limits:* On the north the Red basin, on north-west and west the lofty north-south ranges continuing the Szechwanese Alps through western Yunnan. On the north-east the basin of the lower Yang-tze; on the south-east the upper basin of the Si-kiang. The natural limits to south and south-west are beyond the political frontier of China, thus including within this natural region much of the Shan plateau of upper Burma and the Laos country of northern Siam.

Provinces included within this natural division: Kweichow, central and eastern Yunnan and western borders of Kwang-si.

Essential characteristics: A high tableland of sedimentary rocks, trenched by deeply incised valleys with torrential streams. Great climatic contrast between temperate character of high plateaux and sub-tropical to tropical conditions of valleys with jungle vegetation. Very distinctive plant species.

Orientation of Region: Very isolated and unlike the Red basin not in itself a focus. Essentially a borderland, difficult of access from any direction. Easiest maritime connection with Gulf of Tongking (French Indo-China) but on landward side the best approaches, although very tortuous, are from lower Yang-tze and Szechwan.

II. THE PEOPLE AND THEIR CIVILIZATION

China at the present time is passing through the most momentous transformation in her history; affecting every aspect of life: economic, cultural and political. The essential features of her traditional civilization were developed and established three to four thousand years ago in the basins of the Hwang-ho and the Yang-tze. The great isolation of this area of characterization—separated from the West by arid High Asia and from India by the lofty mountain chains and valley-jungles of Indo-China—accentuated and stereotyped social conceptions already strongly marked. It has been said of China that "no other nation with

NATIVE TYPES IN CHINA

1. A Manchu type
2. Chinese soldiers off duty
3. Three women; characteristic types of southern China
4. Boy of the middle class

5. A mixed type common on the northern and western borders
6. Young Pekingese of the middle class
7. Court of Pekingese temple; man of mixed border type
8. Peasants from the northern provinces of China

which the world is acquainted has preserved its type so unaltered . . . has developed a civilization so completely independent of any extraneous influences . . . has elaborated its own ideals in such absolute segregation from alien thought." This generalization underestimates the debt of early Chinese civilization to external sources, but in substance it is true, and enables us to appreciate the strength of the initial resistance to change when at long last this ancient culture was brought into active contact with the entirely different civilizations of Europe. Throughout the 19th century the European conception of the Chinese was of a people immobile, uniform, unchanging and virtually unchangeable. But the impact of Europe on China is relatively very recent. During the 19th century it affected little more than the fringes of the country and its external political framework. Now its influences have begun to penetrate to the foundations of Chinese civilization, foreshadowing changes in the social and economic fabric, and in the traditional philosophy and ethical outlook of the people of greater significance than the more dramatic changes in the political sphere. The ultimate effects on the structure of Chinese society of the changes in the material environment and on the Chinese mind and character of the flood of new ideas, at once disintegrating and liberating, are beyond prophecy, but no generalizations can be valid which do not allow for the great vitality and adaptability of the racial stock. In the consideration of the various aspects of Chinese life it seems better to stress those elements inherited from the past which count for most in the present and the future, and to indicate the character of the new forces than to attempt an adequate description of the traditional civilization.

Population.—It has been said with some force that estimates of the total population of China have "assumed the importance of an indoor sport, unencumbered by any definitely established rules." The highest reasonable estimate of recent years, the Post Office census of 1920, returned a total of over 427 millions for China Proper (including Manchuria). Allowing 11,000,000 for Mongolia, Tibet and Sinkiang we have a round total of 438,000,000. At the other end of the scale the census of the Board of the Interior in 1910, the year before the fall of the Manchus, put the figure for China Proper with Manchuria as low as 331 millions. Rockhill, admittedly one of the greatest authorities, is inclined to support this figure. The total population of China may be put at about 400 millions, but probably less rather than more. It is approximately one-fifth of the total population of the world. Particularly important is the extraordinarily uneven distribution and almost unparalleled density in certain large areas. The great bulk of the population of China is contained in the following regions:

(a) The central portion of the northern plain round the convergence of Chihli, Shantung and Honan on the alluvium mixed with loess of the lower Hwang-ho basin.

(b) The triangular tract of the Yang-tze delta with its apex at Nanking.

(c) A relatively narrow coastal belt extending southwards from the Yang-tze mouth through Chekiang, Fukien and Kwangtung to the Si-kiang or Canton delta, where it widens considerably.

(d) The Central (Hupeh) basin with the triple city of Hankow-Hanyang-Wuchang as its node and extending up the radial valleys converging on it (Han, Siang, Kan, etc.).

(e) The Red basin of Szechwan, isolated far in the west beyond the Yang-tze gorges.

In the first three of these regions the density of population can hardly be less than 1,000 to the square mile and in many districts it is very much more. The Famine commission estimates nearly 7,000 to the square mile in parts of the rice-growing provinces of Kiangsu and Chekiang (Yang-tze delta) and to 3,000 in parts of Shantung. The northern belt of maximum population is essentially one of peasant farmers, depending upon the land; large cities are rare and industries relatively few. In the Yang-tze delta, the coastal zone and the Canton delta, agriculture greatly predominates, but in addition there are industries old and new and active river or maritime commerce. The merchant classes form a bigger element and great cities are numerous. That

these great regions as a whole, but particularly the northern (Shantung) are supersaturated with human beings relative to the present means of subsistence there can be no question. It is attested by the appalling frequency of famines in the north (about one in every five or six years) and to a less extent in the Lower Yang-tze, and by a very low standard of comfort which yet allows of no margin. In some districts 50% of the families have incomes below "the poverty line."

Outside these limited regions which do not form more than about 15% of the total area of China, population is dense only in isolated valleys or small basins. In the provinces of the loess plateau (Shensi and Shansi) the density is moderate and the population fairly evenly distributed. The same may be said of the south China plateau as a whole. In both well-peopled valleys contrast with sparsely-occupied highlands. The south-western provinces (Kweichow, Yunnan and Kwangsi), Kansu, the new provinces which are being formed out of Inner Mongolia in the north-west and the three Manchurian provinces in the north-east have all at present distinctly low densities, and, although in different degrees and affected by different factors, present great opportunities for future colonization.

About 80% of the people of China are either farmers or closely dependent on the land. Recent estimates indicate that only about 6% live in cities of 50,000 or over, another 6% in towns of from 10,000 to 50,000 and the remaining 88% in places of less than 10,000. It is calculated that there must be in China at least 100,000 farm villages with a population of say 100,000,000 and at least 1,000,000 hamlets with a population of say 200,000,000.

The Chinese have been throughout their history a colonizing race, but the mobility of movement from congested and over-peopled regions to sparsely-occupied areas has been constantly held in check by the great reluctance, for reasons connected with their social philosophy (*see below*) to leave their ancestral homes. This is least true of south-east China. There has long been an increasing stream from Fukien and Kwangtung with their densely-peopled coasts to the rich peninsulas and islands to the south, where they have helped to develop the Far Eastern tropics. In Japanese Formosa they form three-fourths and in British Malaya nearly one-half of the total population. In the Philippines, in Java and Siam and many other parts of the East Indies and Indo-China their vigour, frugality and tenacity make them a prosperous and progressive element, and almost invariably that with the greatest natural increase. These same qualities often constitute a menace to the economic prospects of the less energetic native peoples. These important and thriving Chinese communities of the Far Eastern tropics, although generally, as in Malaya, contented citizens of an alien power, retain close contact with their ancestral provinces which receive large remittances from them and are influenced by them in many ways.

The peoples of the congested districts of the north in Shantung, Chihli and Honan have until recently been much less adventurous. The rich grasslands of Manchuria beyond the Great Wall only became available for agricultural settlement under the Manchu dynasty, and economic development was very slow until after the Russo-Japanese War of 1904-05. With the rapid development of railways, new cultures and industries Manchuria has now become a very attractive field. North China on the other hand has been devastated by famines and during the last few years, the ravages of civil war. The almost intolerable conditions of life in many districts have so weakened old prejudices that a tremendous mass movement is in progress. It is no longer a mainly seasonal migration of males, but a wholesale exodus of families. The increase of population in Manchuria in the four years 1923-27 is estimated at two millions and the exodus from north China during the summer of 1928 at 40,000 a week. The density of population in Manchuria according to the Post Office estimate of 1923 was only 61 per sq.m., and large areas of fertile land are still available, particularly in the north. Whatever the political status of Manchuria may be, its population will inevitably be overwhelmingly Chinese, a population, too, of the "selected" type associated with pioneers in a new country with a stimulating climate. To this great field of colonization in the north must be

added the adjacent districts or provisional provinces of Inner Mongolia on the Chinese side of the Gobi desert, with very considerable pastoral possibilities which the new Peking-Kalgan-Suiyuan railway is making accessible. Northern China has thus a real "land of promise" along her whole northern border and a much needed redistribution of population is in sight. The tendency to overpopulation, however, which is the root cause of the grinding mass poverty of so many districts, and which underlies so many of her problems, is due essentially to social causes and a modification in the traditional social philosophy of the people is alone capable of removing it.

Chinese Society.—In preceding paragraphs the diversity of China has been emphasized. But more significant than the diversity is the cultural unity which has held Chinese civilization intact for more than four millennia. M. Hovelague has expressed it in a very striking passage which, if somewhat exaggerated and, as descriptive of the modern position, somewhat misleading, rivets attention on the most salient feature of the historic China. "Everywhere," he says, "under the blazing skies of the far south as in the icy north, one feels the same weight of abstract and all-powerful influence which, stronger than any differences of climate, race, circumstance or destiny, inexorably mould mankind, imposing everywhere an identical civilization, an absolute moral unity in the diversity of a country which is in itself a continent. All China is thus present in every corner of its vast expanse and at every moment of its history: the mysterious force, which through thousands of years, has fashioned these myriads and immobilized them in their immutable habits is the supreme reality of this land: and this force is a social one" (Émile Hovelague, *China*, translated by Mrs. Laurence Binyon). The basis of this fundamental unity is the family system which has dominated Chinese society and permeated almost every aspect of economic and political life. The sanctity of the family corporation finds expression in ancestor worship, the oldest and most tenacious form of religious expression. It is the cornerstone of the Confucian teaching, accepted by 70 generations of Chinese, a teaching which gives first place to the virtue of filial piety and discourages children from going far away from their ageing parents. It is the *raison d'être* of most of the ceremonial prescribed by the "etiquette" to which Confucius and all his interpreters attached immense importance, and which, under the Imperial régime, a special Government department (the Board of Rites) existed to maintain: the elaborate and expensive rites connected with marriage and death, the maintenance of ancestral halls, the family reunions at fixed seasons, the erection of memorial arches to virtuous widows who refuse to re-marry and countless other symbolic acts. In comparison with the family the individual counts for little. To it he owes implicit loyalty. Marriage, for example, is a contract between two family corporations arranged without reference to the individuals concerned, usually when they are both young children and often without their having seen each other. The family in its extended form as a clan has served the function of insurance and benevolent societies in Europe and the provision of clan funds for education has enabled many a promising boy, by passing the classical examinations, to qualify for public office. The association of families in a community provided a system of local government enabling village and district life to maintain an effective organization even during periods of political anarchy. The group of elders, selected from the wisest and most experienced heads of families, combines many of the duties of an English parish council, board of guardians and bench of justices of the peace, and deals with the higher State officials. Their meeting place, the village temple, is the centre of social life. So, too, the offices connected with the affairs of the village are held in succession by the principal family heads. Thus the basis of the system of government is or has been patriarchal. The old China was in a sense a social democracy of myriad family corporations, whose relations were determined by an elaborate social code requiring obedience to an emperor who was himself regarded as at once the supreme patriarch and the "Son of Heaven," with power equalled only by his responsibility. If by his actions he incurred the wrath of the Spiritual Father on

the immense family which he represented, he had plainly "exhausted the Mandate of Heaven" and revolt against him was justified. The bureaucracy through which he worked was immensely complex, and intended to counter-weight local and provincial interests, but the same patriarchal conception is seen in the functions of and the attitude towards the district magistrate, the head of the *hsien*, the one State official with whom the masses in the countryside and smaller towns come into close contact. Popularly known as the "father and mother" official, the *hsien* magistrate, who survives all the recent changes, is entrusted with a great variety of duties, and under the old régime essentially represented to the people the paternal function of the emperor. In the city of Peking the Temple of Confucius, with a large hall preserving the ancestral tablet of the sage enshrined in an alcove, adjoins the Hall of Classics, where the emperor came on State occasions and whose courtyard contains 300 stone steles on which the complete texts of the "nine classics" are inscribed. The juxtaposition of two of the most famous buildings in the country symbolizes the intimate relationship between the massive social fabric based upon the family and the traditional scholarship of China. This scholarship of high antiquity and unique continuity furnished alike the sanction of the social system, its support and its cultural background. Ethical teaching about social obligations, summarized in the five relationships (sovereign and subject, parent and child, husband and wife, senior and junior, friend and friend) lay at the heart of a moral code already hallowed by antiquity when Confucius gave it coherence. It was largely through schools provided by the family or clan for its own members that the rudiments of its teaching were given to the rising generation. By a graded system of public examinations, proficiency in this learning in its more advanced aspects was tested as the qualification for public office on the principle that only those were fit to be entrusted with affairs of State who understood the foundations on which society rested. Thus the scholars were the governing class and formed the only aristocracy recognized in China since the abolition of the so-called feudal system in the 3rd century before Christ. They enjoyed immense prestige and ranked first in the four recognized groups (scholars, farmers, artisans, traders). They could not transmit their offices to their children, but in practice retired officials had exceptional means for giving them the necessary education, so that many families had at once wealth, usually invested in country estates, and literary traditions, and constituted the *litterati* or gentry, the notables of the countryside and small towns. Yet they were never a caste apart, and their ranks were open to any peasant's or craftsman's son who could qualify. The recognition of an aristocracy of learning, the recruitment of the civil service by competitive public examinations (from the time of the Han dynasty) and the absence of caste distinctions were three outstanding features of the old Chinese civilization complementary to the patriarchal system and adapting it to a complex State organization. They are among the finest elements of the inheritance which has to be adapted to meet the changed requirements of modern China.

But the most important aspect of adaptation concerns the family system itself. To it China undoubtedly owes the remarkable social stability which has enabled her to survive the many shocks which the political fabric has received and to outlive many far more highly organized communities. Many of the most attractive aspects and some of the most fundamental virtues of the Chinese character are almost indissolubly bound up with it. Yet the cult of the family is the primary cause of the intense pressure of population on the land. In the long formative period of Chinese history, when cultivation in the midst of undrained swamps and forest jungles called for the maximum of co-operative effort, there was a strong economic justification for the propagation of large family groups to which ancestor worship, and later the Confucian teaching, gave a sanction and force of religious intensity. But this sanction has long outlived that phase of economic development and there is left what J. O. P. Bland has called "the procreative recklessness of the race, that blind frenzy of man-making, born of ancestor worship and Confucian-

ism, which despite plague, pestilence, famine . . . persistently swells the numbers of the population up to and beyond the visible means of subsistence. By means of polygamy, early marriage and the interdependence of clans, the Chinese people struggle to fulfil at all costs the inexorable demands of their patriarchal system." The first result of this chronic tendency to over-population, in a country so largely composed of peasant proprietors and where no law of primogeniture exists, is naturally the excessive subdivision of land. According to the Famine commission's investigations in certain districts of north China and the Yang-tze delta, 33% of the family holdings were of less than one acre and 55% of not more than one and a half acres in extent, and the significant comment is added: "the average size of the families who have as much as one and a half acres is 5.7 and the number in the families increases with the size of the holdings." The abnormally low standard of living and the absence of a reserve explain in their turn the existence of a "submerged tenth" of desperate men, ready to adopt brigandage. Hence the contrast between the singularly peaceful and law-abiding character of the Chinese as a whole and the frequent disorder and terrorism in country districts when authority is relaxed. Hence, too, the ease with which armies can be raised in a country essentially unwarlike and the extreme difficulty of disbanding them once they have come into existence. Excessive emphasis on the family is also a potent cause of China's political weakness, since family-interests have been constantly preferred to those of the State. Nepotism in fact has been described as a religious duty in China, an obligation to use public office for the benefit of the family group as the supreme object of loyalty. Many individuals have attained to a larger vision but usually there has been a marked contrast between the admirable honesty and trustworthiness of the Chinese in their individual and trade relations and the corruption which has tended to characterize their public life and to ruin large-scale undertakings lying outside the traditional group organizations. The State, as such, has until recently meant very little to the vast majority of the Chinese people. The vast size of the country, the relative uniformity of her culture, the absence until modern times of rival political organizations in close contact with it, all militated against the development of a sense of nationality as understood in the West. China has been a civilization rather than a national entity in the European sense. The loose association of family and other groups permeated by this civilization are only now becoming conscious of a larger unity as the result of the poignant experiences of the last century of their long history. China, as the sub-title of a recent study aptly suggests, is "A nation in evolution." That is perhaps the best description of the slow, painful and fateful transition now in progress.

Many influences are at work in modern China to reduce the importance of the joint-family and to disintegrate the traditional structure of Chinese society. The most important effects of industrialism are at present localised in the cities of the Yang-tze and Canton deltas, the central basin, at nodal points along the main railways and at several of the sea-ports, but its indirect influences spread much farther afield. In these cities there is now a large and increasing class of industrial workers of a type quite new to China. They are losing touch with the corporate life of the countryside and are increasingly detached from the traditional social heritage. A large proportion of them are women, and the entrance of women into large-scale factory industry implies at once their growing economic independence and the break-down of the clan system. Nor is that all. Industry and commerce in China were formerly almost entirely controlled by the guild system. The guilds are group organizations of various types but like the family organization all make the well-being of the individual dependent on his obedience to the code governing the interests of his craft or trade or, in the case of provincial and city guilds, of his locality. In the main they have been essentially democratic and have emphasized not the separate interests of employers and employed but the solidarity of the trade. Loyalty to them, as for example in the matter of submitting books for inspection by guild officials, has been as conspicuous as loyalty to the family. Large-scale industries of

Western type employing the new class of artisans are for the most part outside the guild system, and the workers, often living under conditions similar to those of the factory towns of England in the early days of the Industrial Revolution, are open to the appeal of new influences such as the Western trade union movement and Communism. That the old capacity for combination is capable of taking new forms is shown by the many examples in recent years of relatively successful strikes and boycotts.

China may in time work out a new form of industrial democracy consonant with the spirit of her ancient institutions. The segregation of classes is wholly alien to her traditions and the idea of the class war was expressly repudiated by Sun Yat-sen, the founder of the Kuo-min-tang or people's party, regarded by most reformers as the father of the new China. The guilds have not yet lost their vitality, and some experiments have been made in combining separate trade-guilds into larger industrial unions adapted to the modern business world. Much will depend upon the relationship of the guilds to the chambers of commerce, a new and significant feature of commercial organization in China. These chambers are primarily associations of business men and form one of many evidences of a growing solidarity and steadying power of merchant opinion. They herald the emergence of a middle class, whose links, however, with the mass of the workers are at present much closer than in most Western countries, and which has by no means lost the conception of social solidarity. Promotion of good relations between employers and workmen is an avowed object of the chambers and in some cases they represent the guilds.

Of the new cultural forces the most outstanding are the modern educational system, the student movement and the penetration of new ideas from Europe, America and modernized Japan. The sudden abolition of the old classical system of examinations in the last years of the Manchu dynasty marked a dramatic break probably more fundamental in effect than the abolition of the Imperial Office six years later. In the final section on Administration an outline is given of the new national scheme of education which, though still in an early and experimental stage, has been launched in the face of infinite difficulties during troubled years. The most revolutionary of its social influences are (1) the granting of educational facilities to women and the introduction of co-education in primary schools. In conjunction with the economic forces already noticed this is producing a remarkable change in the status of women, a most significant fact. (2) Western science, at present very imperfectly organized in China, but implying a mental discipline of a kind quite foreign to the old literary training. (3) The ideal of mass education. In respect for learning no country has excelled China, but in the past it has always been associated with a relatively small group of scholars. A long time must elapse before there is a sufficiently large number of adequately staffed primary schools; but there are few more promising features in modern China than the almost passionate enthusiasm with which the students and teachers of Government schools and colleges have organized the popular educational movement, devoting evenings and parts of vacations to the conduct of free schools, for poor children and adults. The popular vernacular (*Pai-hua*) of the Mandarin dialect is being made the accepted medium for new literature, in place of the old classical and "dead" language, which presents far greater difficulties. The change, virtually accomplished, is comparable in character and importance to the adoption of the vernacular as the medium of literary expression in place of Latin in Chaucer's England and Dante's Italy. Further, out of the vast number of Chinese characters, 1,000 (or even 600) of the most essential have been selected for use in the people's schools—hence often called "foundation character schools"—and are exclusively used in the writing of appropriate popular books. The alternative method of a phonetic alphabet, in which extensive experiments have been made, seems likely to be discarded in its favour.

These important linguistic reforms, especially the development of the new national language (*Pai-hua*) are to a large extent the outcome of the remarkable movement known as "the new tide"

or Chinese renaissance. This movement, associated with the new "intelligentsia" in the chief centres of thought, such as the National university at Peking, owes its origin to returned Chinese graduates of foreign universities (especially Paris and certain American universities), and in particular, on its literary side, to Dr. Hu Shih, often called "the father of the Chinese renaissance." It witnesses to an intellectual ferment similar in many ways to that of the renaissance and reformation period in Europe. On the literary and linguistic side it has been essentially constructive. In most other respects it is at present mainly destructive and critical. Especially notable is its vigorous and unsparing attack on the inferior status of women, child betrothals and costly expenditure on funeral rites. On its more speculative side it is concerned with what its exponents describe as a "revaluation" of Chinese thought and philosophy in the light of Western science and knowledge. In the sphere of religion it is for the most part sceptical and rationalistic and, in conjunction with the political agitation of recent years, has helped to give birth to a widespread but probably rather transient anti-Christian movement in the ranks of "Young China." At the same time the movement in many of its aspects includes some of the most distinguished of the leaders of Chinese Christianity.

This movement has had great influence on the large student class. The counter-attraction of political agitation has no doubt recently absorbed an excessive proportion of student time and energy, much of it misdirected. With the development of more stable political conditions and better international relations, this may turn out to be but a passing phase and "the student movement" may be re-orientated to its real task of social, cultural and economic reconstruction. For, in the absence of a class of hereditary leaders, such as carried through the transformation of Japan, the pioneers of reconstruction in China must inevitably be drawn from the student class, and it is almost impossible to exaggerate the part which they can play. Their leaders inherit the prestige which was always enjoyed by the old-time *literati* and the absence of caste distinctions brings them into far closer and more intimate contact with the peasantry than in most oriental countries. In the last analysis the wise direction of education underlies all specific reforms. The disintegrating effects of the new influences inevitably invade the religious sphere, but in certain respects the break with the past is less complete and revolutionary than in other aspects of life. This is due to two main causes: (1) The fact that religious beliefs in China have never been held with the same tenacity, certainty and fanaticism as in India or Mohammedan Asia. China has been strikingly free from religious bigotry and from wars of religion. Anti-Christian movements and occasional persecutions have been inspired rather by fear or misunderstanding of foreign influence. (2) The nature of the prevailing religious systems. Of the three historic religions of China (*see under History*), Taoism in its later phases has been little more than a congeries of superstitions which must gradually lose their vitality. The same may be said of the cruder side of popular Buddhism, especially in its northern form (Lamaism), but in its more philosophical aspects Buddhism has a definite adaptability and is by no means a negligible factor. Confucianism, although it has a religious aspect, denotes a social code and an attitude towards life, rather than a religion. Although obviously no longer adequate to the changed conditions it retains great vitality; it forms the mental background and in part orientates the lives of many educated Chinese who hold no religious beliefs at all definitely. There is little in Confucianism which is incompatible with either Buddhism or Christianity. The China of the future is likely to provide a relatively free field for religious propaganda of many kinds. The average attitude of the majority of educated Chinese may probably be described as agnosticism, coloured and softened by Confucian and Buddhist tendencies. The influence of Christianity is considerably greater than the relatively very small number of its adherents would indicate, and the marked tendency to adapt it to Chinese modes of thought and organization will almost certainly increase it. The Christian community has already played a part in the public life of China out of all proportion to its numbers; nor is the influence of the missionary

schools and colleges to be measured by the sum total of professed converts. Against stark materialism, which in a China unrestrained by the ancient loyalties but fortified by modern science would be the greatest menace to the world, Christianity can join forces with all that is noblest in Buddhism and Confucianism alike.

Thus in modern China "the old order," stable for four millennia "changeeth, yielding place to new" and the time-honoured social grouping of scholars, farmers, artificers and merchants must grade into a much more complex society. Yet many-sided as is the revolution through which the country is passing, prolonged as must be the social turmoil and difficult the new integration, there are many valuable elements in the heritage of the past still vital and making for stability. If these can be preserved and reorientated to serve the purposes of a new national life, inspired by a widened scale of social values, China may yet eclipse her greatest achievements under the most famous of her dynasties.

III. PRODUCTION, COMMERCE AND COMMUNICATIONS

Even on the most generous estimate of industrial prospects, China will remain a preponderantly agricultural country. The future relationship, however, of agriculture and manufacturing industry is a matter of great interest. Development of electric power and improvement of transport would render possible diffusion of small-scale industries better suited to Chinese traditions and genius than the large-scale factory system, and, if accompanied by the growth of co-operative agencies, may greatly improve the conditions of the countryside.

AGRICULTURE

Characteristics of Chinese Agriculture.—Chinese agriculture is primarily distinguished by its intensity. It supports the greatest number of people per unit of land in the world, estimated at five persons for every two acres as compared with one person per two acres in western Europe. This is only made possible by the unremitting labour which the struggle for existence demands and the traditional skill born of 40 centuries of transmitted experience. The maintenance of soil fertility under constant intensive cultivation for such an immense period is in part secured by replenishment with canal mud, as in the Yang-tze delta, or by the silt deposited by river-floods (otherwise disastrous), but in the main by the use of "night soil" and every possible kind of manure, applied to the land in primitive but effective fashion. Soil is composted with organic matter and ashes and then dried and pulverized to form a plant-food. De-forestation has taken place not simply to make room for more arable land but as the result of a constant quest for green manure. In hilly districts, such as the loess plateau and the Red basin, the fields on the valley slopes are terraced and rimmed so that the run-off may be retained until the suspended matter has settled. Again, in crop rotations legumes have always been grown for fertilizing the soil. So the growing season is lengthened and a system has been evolved whereby two, three or even four crops are grown in the same ground-space each year, while as many as three crops, each in a different stage of development, grow simultaneously in one field. In few countries has the practice of multiple cropping been so perfected. The great traditional skill of the Chinese has raised their agriculture to the level of an art; they show, moreover, remarkable ingenuity in adapting means to ends, as in the many uses to which they can put bamboo or millet. Their implements, too, are effective, if primitive. On the other hand, the typical Chinese farmer knows nothing of science as applied to proper seed selection, experiments in better crop rotations or animal breeding. His methods are essentially conservative and traditional and, except in Manchuria, little use is made of chemical fertilizers. Notwithstanding great industry at certain seasons, there is much unutilized idle time in winter, especially in the north, which the development of small rural industries on a co-operative basis would employ to great advantage in the farming community. As yet there is little combination for the purchase of seeds or implements or for the marketing of produce. Some important experiments to remedy these defects are definitely connected with provincial effort, as notably in Shansi and Kiangsu; others are associated with agricultural colleges or

departments, such as those maintained by the University of Nanking (an American union missionary college) for the development of scientific sericulture and cotton cultivation. In parts of north China co-operative village banks have made a very promising beginning and the mass education movement is becoming an important factor. Development on the lines associated with the Danish folk school movement, so closely linked with the success of the co-operative societies, is the ideal of many workers in China.

Agricultural Regions.—The salient characteristics of the major agricultural regions can most easily be summarized in relation to the scheme of the natural divisions of China already discussed, except that the essential features of crop production and farming methods in the Red basin closely resemble those of the lower Yang-tze valley.

(1). The Tsin-ling mountain complex delimits the agricultural "province" of north China. Here severe winters and the short and rather uncertain rainy season preclude winter crops. It lies beyond the limit of the cultivation of wet rice, which as a staple crop is replaced by millets and wheat. Rice, it is true, is a subordinate crop in favoured districts of north China; it is known, however, as small rice and is really a glutinous millet. Most people live on wheat and millet, while meat (other than pork) and potatoes play a part. There are differences between the loess plateau and the alluvial plain.

(a) The soils of the loesslands are of unusual fertility owing to their fine texture, their porous and friable nature and the presence in them of soluble mineral matter for plant nourishment. On the other hand, the region is the driest in China, and, except in the basins, is incapable of manual irrigation. Arable cultivation is therefore often precarious and there is greater reliance on sheep and cattle. In the extreme north-west pastoral products and some associated manufactures of coarse woollens and cloths are the principal products. Here occurs the greatest concentration of sheep, raised primarily for wool. Cattle, elsewhere in China almost exclusively draught animals, are raised in the north-west for grazing and dairying; there are distinct prospects for the dairy industry in Inner Mongolia and for extensive developments of leather and woollen manufactures in many parts of the loess belt. In the loess basins such as Taiyuan-fu and Tatung-fu, where well-irrigation and terrace cultivation reduce the risk of crop failure, the harder cereals are often accompanied by fruit culture (apples, pears, plums, walnuts, apricots, strawberries and the jujube) and also by cotton. Recently a large proportion of the land in Shensi and Kansu has been under the opium poppy. (For agriculture in the north-west see INNER MONGOLIA, SHANSI and KANSU.)

(b) The plain of north China east of the Tai-hang-shan, which forms the edge of the loess plateau, has a slightly higher rainfall but risk of flood is much higher and the great problem is the control of the Hwang-ho, Hwai and the northern rivers. The main reliance is on wheat, barley, millet, buckwheat and maize, together with vegetable crops, especially beans and peas. Rice is grown in southern Shantung and northern Kiangsu, *i.e.*, on the borders of the Yang-tze "province," and cotton in Shantung and Chihli, but there is little room for any but subsistence crops. In Shantung there are three crops in two years, the usual rotation being wheat in spring, beans in autumn and finally millet, which is gathered in the following September. Or as an alternative, wheat or barley in winter and spring may be followed by large or small millet, sweet potatoes, soy beans or peanuts in summer. Animals are less important than in the north-west, but in the parts of Chihli adjacent to Mongolia there is the largest concentration of horses, mules and draught animals to be found in China proper.

(2). The Yang-tze "province" with rich alluvial basins, relatively high, well-distributed rainfall, seasonal rhythm of moist sub-tropical summers and mild winters and magnificent natural waterways, is one of the most favoured agricultural regions in the world and the premier granary of China, supporting nearly half of her total population. The combination of summer "wet" crops and winter "dry" (temperate) crops give it a marvellous range of production, and most of the staple products of China, whether subsistence or commercial crops, find here their optimum conditions.

It is easily first in the production of rice, the chief food of all central and south China, the order of the leading provinces being Kiang-su, Hunan, Hupeh, Anhwei, Kiang-si, Szechwan, Che-kiang, Kwangtung. If Chekiang be included, it produces over 68% of the total output of silk, the oldest and most famous of Chinese commercial products, and about 60% of that of cotton, one of the chief factors in the new industrial development. It is also the largest centre of tea production. In some districts, as in parts of the Yang-tze delta and the central basin, the rotation is determined by the needs of a special crop. In the normal agricultural year barley, wheat, beans and peas are sown early in winter and harvested in May (wheat in June), followed by sesamum, sown after the wheat harvest and ripe early in September, while rice may be either an early crop, planted early in April and ready for harvesting 90 days later, or a late crop planted in early June and harvested after 110 days. If rice is grown for commercial purposes it receives special attention and the fields are ploughed and prepared in early winter. Cotton lands also require special preparation. While this is the régime of the lowland basins, the uplands of central China, especially between the Tung-ting and Po-yang lakes, are associated with the cultivation of the tea plant and the tallow tree.

(3) The south-east China highlands are not unlike those of central China and the ranges of Fukien form the second great tea-district, but the valleys and basins, with more abundant rainfall and warm winters, can grow sub-tropical crops all the year round. In the most favoured regions such as the Canton delta there are two or even three rice crops in the year and the sugar-cane finds its optimum conditions. Almost confined to this section of China are the pine-apple, spice-yielding plants as cinnamon and cassia, ginger and aniseed. The southern coast of Kwangtung and the island of Hainan, with an exceptionally high rainfall and uniformly hot conditions, are particularly associated with these tropical cultures. On the other hand the climate of south-east China is too moist for cotton and for the "dry" cereals which form the winter crops of the Yang-tze valley.

(4) The south-west is the least developed of all the major regions of China. The high plateaux are scenes of pastoralism and sporadic cereal and poppy cultivation, but the deeply-cut and generally narrow valleys, with a damp, unhealthy climate, and often still choked with luxuriant jungle vegetation, have not been intensively developed as have the more open and accessible basins of the south-east.

Special Products and Associated Manufactures.—Of necessity subsistence crops are of far greater importance in China than commercial products, and this is strikingly shown by the fact that the three greatest food-crops—rice, wheat and millets—occupy 69% of the cultivated area.

Rice, the staple food in central and south China, takes up no less than 28% and has first choice of the land. More than half the land under cultivation in Kiangsu, the richest province, is devoted to it. Yet only four provinces, Hunan, Anhwei, Kwangsi and Kiangsi have a surplus over local needs, and although the average annual production in China reaches the enormous total of 400,000,000 piculs (of 133½ lb.), large imports have to be made each year from French Indo-China, Siam and Korea.

Wheat comes second to rice in importance, and replaces it as a food crop in north China owing to climatic conditions. In some northern districts it occupies 40% of the cultivated land. The normal annual crop is estimated at 600,000,000 bushels (of 60 lb.) but there must be considerable imports of wheat and flour. The number of wheat-eaters is steadily increasing in northern China, especially in the towns. The annual output, however, can be much increased through both extension of the wheat area by "dry" farming in the marginal lands of Inner Mongolia and Manchuria and an increase of the rate of yield, at present low. Flour-milling has made notable advances, especially in Manchuria, and in 1925 there were about 150 modern mills.

Millets and sorghum, whose distribution is rather wider than that of wheat, occupy 20% of the cultivated land area of China. They are dominant in Chihli (Hopeh), Shantung and Honan where they take up one-third of the agricultural surface. Apart

from the grain, their by-products are of great value, and in north China the stalks and fibre of the *kao-liang* replace, for many purposes, bamboo which reaches its northerly limit in the Wei-ho valley.

Tea has long been the chief beverage in China, and since at least the 8th century A.D. the cultivation of the tea plant has been a great agricultural industry, localized mainly on the uplands of central China and on the ranges of the maritime provinces, but important also in Szechwan. Black, green and "brick" teas result from different processes of manufacture. The tea plant in China is mainly grown in patches round the homestead, and the methods both of cultivation and preliminary preparation after the picking of the leaves (usually in April, mid-May and August) are traditional and not based on scientific knowledge. Mainly for this reason the chief European markets for black tea were largely lost by China in the later 19th century, when the plantation system, with its associated scientific processes of manufacture, was developed in India and Ceylon. Of the 400,000 piculs of black tea exported from China in 1924 Great Britain took 164,000. Brick tea, made by pressing damp leaves into a brick-like mould, finds its chief market in Tibet and interior Asia. The chief ports for tea-export are Hankow (black and brick tea), Kiukiang and Foochow (black tea), Hangchow, Ningpo and Kiukiang (green tea). Experimental stations and investigation bureaux for more scientific cultivation and preparation of tea have been opened in the Yang-tze valley and at Foochow, and a small beginning has been made with the plantation system.

For sericulture, the most far-famed and ancient of her industries, China has many natural advantages, including the two or more leafings of the mulberry, as compared with one in the Mediterranean countries, and abundant cheap and traditionally skilled labour in the manipulation of the cocoon and in weaving. In the production of raw silk there are many regional specializations in accordance with the variation of soil and climatic conditions. The silk of the north (Shantung and Manchuria) is chiefly "wild," the product of silk-worms fed on oak leaves and manufactured into coarse-textured tussahs and pongees; the Canton delta, where there are as many as six or seven leafings of the mulberry, produces soft Canton silk and Szechwan a special yellow variety. But the most renowned silk region is the lower Yang-tze valley, the finest white silk in the world (tsatlee) coming from around the Tai-hu Lake. The aggregate output of raw silk in China is estimated at 25% of the world's supply, but the exports to European and particularly American markets, although considerable, have in recent years been surpassed by those of Japan, which has added scientific technique to the natural advantages for silk production which she shares with China, where the industry is carried on by the peasants on traditional lines. Serious efforts are now being made by special departments of several colleges and by the International Committee for the Improvement of Sericulture in China to improve the mulberry plantations and to eradicate silk-worm diseases, which greatly impair the prosperity of the industry. A more revolutionary change is indicated by the development of large steam filatures and weaving mills at Canton, Shanghai, Soochow, Hangchow, Hankow, Chefoo and Chinkiang and other towns. There are indications that, with improved methods, China may be able to challenge the dominant position of Japan in the American silk market. Even under present conditions, raw silk and cocoons form over 18% of the total value of Chinese exports and come second only to that of beans and bean products. In contrast, tea, which in 1820 constituted 75% and in 1867 60% of all Chinese exports, accounted for little more than 3% in 1926.

The most remarkable agricultural development in China during recent times has been the rapid growth of the bean industry. Beans have long been grown as an article of food, but the development of the culture on a commercial basis is quite modern and is due to the realization of the many valuable qualities of the soya variety, which is admirably adapted to north China, and particularly Manchuria. On the one hand, it has a higher food value than any other seed which, in conjunction with its cheapness, makes it an effective substitute for milk, meat or the staple

grain foods of north China; on the other its by-products—bean-oil as a cooking sauce, as a base in soap-manufacture and as a lubricant for various purposes, and bean-cake as a fertilizer and cattle food—are of great commercial value. Beans and bean products now amount to one-fifth of the total exports of China and are one of the principal factors in the rapid economic development of Manchuria. (See MANCHURIA.)

Of the purely industrial crops of China, cotton is the most important, and its future development will be followed with great interest. China is now the fourth largest producer of raw cotton in the world and the soil and climatic conditions of many districts of the Yang-tze valley and the adjacent parts of the plain of north China approximate to those of the cotton belt of the United States. But the industry at present suffers from many disadvantages: the short staple of the native varieties, primitive methods of seed selection and cultivation, lack of transport and of banking and credit facilities to deal with the movement of crops, and the existence of provincial and inter-provincial *likin* taxes, which greatly raise its price. Much important work is now being done both by provincial associations and college departments (notably the University of Nanking) to improve native varieties and to acclimatize and then distribute seeds of American cottons. It would now seem to be established by experiments that late-maturing American cottons will not succeed in the Yang-tze delta, with its humid early autumn climate, but can be acclimatized in the central basin and parts of north China where September and October are normally dry, sunny months. The endeavour is being made to produce longer-stapled Chinese cottons for the deltaic area.

The great development of cotton mills in China in the last 20 years is the most important aspect of the new industrialism. They are, however, very strictly localized. Of 118 cotton mills in China in 1927, 58 were in Shanghai, the great textile centre, and half the remainder in the Yang-tze delta and the central basin. Of the grand total 72 were Chinese-owned, with 2,218,588 spindles and 12,409 looms, 42 Japanese-owned with 1,302,678 spindles and 9,625 looms and 4 British-owned with 205,320 spindles and 2,348 looms. Over three-fourths of the raw cotton consumed in these mills is of Chinese origin, and practically all the rest comes from India and the United States. The piece-goods produced compete in the huge Chinese market with those of Japan, India and Great Britain. As yet, labour in the mills is very cheap and regulations as to hours of labour, employment of women and children and safeguarding of machinery are almost non-existent. But a movement to improve the conditions of factory labour is gathering force and the workers themselves are beginning to organize. (It is estimated that the total number of workers engaged in large-scale industries of all kinds throughout China is about four millions.)

The opium poppy is still (1928) one of the chief and most widely-distributed products of China's fields, and the area devoted to it, reduced to a minimum by the prohibition orders of 1906 and subsequent years, greatly increased during the period of civil war, with its military exactions of illicit revenues.

Other important Chinese products, which cannot be separately described, include fibre crops, especially ramie in the Yang-tze valley, tobacco (very widely distributed), ground-nuts, many kinds of vegetable-oil, cane sugar and a great variety of medicinal plants and spices.

So great is the need for subsistence crops in China that grazing grounds for sheep and cattle are virtually confined to the dry north-west and to mountain pastures. In the rest of China there is no dairy industry and cattle are used primarily as draft animals. On the other hand, animals such as swine, goats and poultry, which can subsist on by-products of the farm, are kept in large numbers. Of scientific animal breeding there is at present very little. Reference has already been made to the meagre resources of modern China in timber. Schemes for re-afforestation have been promoted in certain provinces, notably Shansi and Kiangu.

China has an important source of wealth in her sea and river fisheries, which are rich and varied and supplemented by arti-

ficial breeding in tanks. The coastal fisheries of Shantung, Chekiang and Kwangtung are especially valuable, and they include some of the world's greatest fishing centres. The annual yield of Chinese fisheries is estimated at \$200,000,000, and fish, both fresh and salted, is a staple article of diet in many districts.

Mineral Wealth and Mining.—The distribution and character of the varied mineral wealth of China in relation to the structure of the country have already been discussed. It remains to examine briefly the economic aspect. Coal is by far the most important item but there is as yet no certainty regarding even the approximate amount of China's coal reserves. The revised estimate (1926) of the Chinese geological survey of 217,058 million tons (M.T.) while much higher than its first estimate, admittedly very conservative, is still far short of the 994,987 M.T. submitted to the International Geological Congress in 1913. Yet they indicate a bulk which is: (1) infinitely the greatest in the Far East; (2) undoubtedly sufficient to form the fuel basis of industrial development in China, however extensive it may be. Of the total amount of the revised Survey estimate Shansi alone is responsible for more than one-half.

While every coalfield has outcrop or adit workings to supply local consumption, about 75% of the total production of 25.7 M.T. is now furnished by large-scale concerns. These are all intimately related to the existing railway systems mainly concentrated in north China, and are therefore chiefly located on the small fields scattered around the edges of the north China and south Manchurian plains. The only really important mine in south China is that of Pinghsiang among the hills of the Hunan-Kiangsi border, and this too is linked with the railway system. Much the largest concerns are the Japanese Fushun and the Sino-British Kailan, whose fields, though small, have each an important strategic position, being in close contact with the railway foci of south Manchuria and of north China respectively. The production of Fushun, now exceeding 5 M.T., is the larger of the two. From these and from other mines in Shantung and along the eastern fringes of the Shansi coalfield, coal is exported along the railways and by coasting steamer to the commercial and industrial centres, of which the Yang-tze delta is the chief. Chinwangtao, the property of the Kailan concern, has a larger coal-shipping trade than any other port east of Suez. There is also a considerable trade, in which exports exceed imports, with Japan.

China's resources of iron are more meagre than those of coal. Tegengren, for the Chinese Geological Survey, estimates the

reserve of ores suited to modern large-scale methods (and exclusive therefore of coal-measure ores) at only 952 M.T., and holds out little hope of the discovery of new deposits. These may be insufficient to form the permanent basis of an iron industry of the magnitude of that of America, but, on the other hand, the Chinese industry has as yet a capacity of only one million tons of pig iron and an actual output of but one-third of that amount. Thus there is room for very considerable expansion. Mining is most active along the lower Yang-tze valley whose mines (Tayeh in particular) account for two-thirds of a total ore production of 1.5 M.T. Next to it in production as an iron-field is south Manchuria, and these two regions are also the chief centres of iron smelting. To both coke has to be carried some distance, but China has no lack of coking coal. It is a noteworthy fact that by various means Japan has acquired virtual control of 90% of the utilizable iron resources of China, and imports fully half of both the latter's iron ore and pig iron production.

Of fuels other than coal, such as petroleum and oil shale, China possesses only limited amounts. This is also true, among the metals, of lead-zinc and of silver, but the resources of copper and tin are by no means insignificant. Small deposits of all these metals have long been worked in many parts of the country. The most important copper and tin mines all lie in Yunnan and adjacent south-west Szechwan. Of some rarer metals, particularly antimony and tungsten, China is the leading producer of the world. In conclusion it may be said that, while the impressions, so widely prevalent in the 19th century, of China as a country of almost unparalleled mineral resources are clearly without foundation, she yet has an ample margin for assured industrial development, and with improved transport facilities and more favourable economic conditions will develop great mining activities. (*See SHANSI, CHIHLI and MANCHURIA.*)

FOREIGN TRADE

The origin and characteristics of the system by which the foreign trade of China has been organized from the middle of the 19th century down to the present time (1928) are explained in the section on *History*. Some impending changes of great importance are indicated below. The following tables showing the total foreign trade for 1926 according to the returns of the Chinese Maritime Customs may be taken as fairly typical of the

TABLE I. *Foreign Trade of China, 1926*

| Principal articles imported (net) from foreign countries. Percentage of total value of imports indicated in brackets | | Principal articles exported to foreign countries. Percentage of total value of exports indicated in brackets | |
|--|---------------------------|--|---------------------------|
| | In thousands of Hk. taels | | In thousands of Hk. taels |
| Cotton goods (excluding cotton yarn and raw cotton) | 177,217 (15.76%) | Beans and bean products | 175,778 (20.34%) |
| Raw cotton | 93,751 (8.34%) | Raw silk, cocoons, etc. | 159,025 (18.40%) |
| Rice | 89,844 (7.99%) | Eggs and egg products | 38,174 (4.42%) |
| Sugar | 82,753 (7.36%) | Silk piece goods | 30,858 (3.57%) |
| Kerosene oil | 56,595 (5.03%) | Groundnuts and products | 29,821 (3.45%) |
| Metals and minerals | 52,347 (4.66%) | Raw cotton | 29,399 (3.40%) |
| Tobacco and cigarettes | 46,578 (4.15%) | Skins, hides, leather | 28,848 (3.34%) |
| Woollen goods | 29,653 (2.64%) | Cereals | 28,722 (3.32%) |
| Cotton yarn | 28,250 (2.51%) | Seeds and seed-cake | 26,583 (3.08%) |
| Fishery and sea products | 27,824 (2.47%) | Coal | 26,189 (3.03%) |
| Paper | 27,669 (2.46%) | Tea | 26,165 (3.03%) |
| Coal | 26,933 (2.40%) | Cigarettes | 15,416 (1.78%) |
| Gums, oils, soap, candles, etc. | 25,854 (2.30%) | Wood oil | 14,962 (1.73%) |
| Flour | 24,820 (2.21%) | Hair, feathers and wool | 14,895 |
| Cereals, seeds, etc. | 23,623 (2.10%) | Cotton goods (excluding yarn) | 13,298 |
| Chemicals | 21,039 (1.87%) | Cotton yarn | 10,812 |
| Hemp, flax and jute goods | 19,936 (1.77%) | Bristles | 10,469 |
| Wheat | 17,965 (1.60%) | Wood and timber | 10,314 |
| Machinery | 16,738 (1.49%) | Tin in slabs | 8,738 |
| Timber | 16,144 (1.44%) | Other merchandise | 165,829 |
| Other merchandise | 218,688 | | |
| Total net imports | 1,124,221,253 Hk. Taels | Total exports | 864,294,771 Hk. Taels |

The Haikwan tael, an uncoined weight of silver used in the collections and statistics of the Chinese Maritime Customs, was equivalent to $3\frac{1}{2}$ d. in English money in 1926.

position during recent years, in spite of the disturbed political conditions.

TABLE II. *China's Foreign Trade with Principal Countries, 1926*

| Country | Direct imports (gross) (in thousands of Hk. taels) | Per-centage of total imports | Direct exports (in thousands of Hk. taels) | Per-centage of total exports | Excess of | |
|--------------------------|--|------------------------------|--|------------------------------|-----------|----------|
| | | | | | Im-ports | Ex-ports |
| Japan | 336,909 | 29.43 | 211,741 | 24.50 | 125,168 | .. |
| United States of America | 187,647 | 16.39 | 150,113 | 17.37 | 37,534 | .. |
| Hongkong | 124,473 | 10.88 | 93,802 | 10.85 | 30,671 | .. |
| Great Britain | 116,269 | 10.16 | 55,836 | 6.46 | 60,433 | .. |
| Russia and Siberia | 22,712 | 1.98 | 64,120 | 7.42 | .. | 41,408 |
| French Indo-China | 51,796 | 4.53 | 18,434 | 2.13 | 33,362 | .. |
| Germany | 45,678 | 3.99 | 17,760 | 2.05 | 27,918 | .. |
| Other countries | 259,163 | 22.64 | 252,489 | 29.22 | 6,738 | .. |
| Total | 1,144,647 | .. | 864,295 | .. | 280,352 | .. |

1. In certain respects the returns for 1926 were exceptional owing to the Cantonese boycott of Hongkong during the greater part of the year which tended to swell the returns of direct Chinese imports from other sources. In 1924 both imports from and exports to Hongkong were nearly double those of 1926. It should be realized that while Hongkong is a "foreign country" from the standpoint of the Chinese Maritime Customs it is essentially a transshipment centre. (See HONGKONG.)

2. The balance of trade is considerably in China's favour in the case of Singapore, France, Russia, Korea, Persia, Turkey and Egypt.

TABLE III. *Tonnage of Vessels Engaged in Carrying Trade from and to Foreign Countries and between the Open Ports of China, 1926*

| | Tons | % |
|-------------|------------|-------|
| British | 47,645,090 | 35.38 |
| Japanese | 38,948,844 | 28.92 |
| Chinese | 28,393,631 | 21.09 |
| American | 6,496,351 | 4.83 |
| Other Flags | 13,175,690 | 9.78 |

TABLE IV. *Percentage Contributed by Principal Ports to Maritime Customs Revenue, 1926*

(Total collection Hk. taels, 80,435,962)

| | % |
|---------------------|-------|
| Shanghai | 41.81 |
| Tientsin | 10.15 |
| Dairen | 8.72 |
| Hankow | 6.60 |
| Canton | 5.74 |
| Kaiochow (Tsingtao) | 4.27 |

Of the total shipping engaged 117,319 were steamers with an aggregate tonnage of 132,249,000 and 41,677 were sailing vessels (almost entirely Chinese junks) with an aggregate tonnage of 2,410,000. An important feature shown by the first two of these tables is the considerable excess of imports over exports and, with the exception of certain years in the eighties, this has been a constant characteristic of Chinese foreign trade since 1869. The interpretation of this excess is by no means easy. It cannot be explained as in the case, for example, of Great Britain, by so-called "invisible" exports in the form of shipping services paid for by imports or by interest on capital invested abroad, which again swells the import list. China has, however, an important asset, which is in some respects comparable to the latter, in the extensive remittances made to their ancestral homes by emigrants to Malaya, the Philippines, the Dutch East Indies, Indo-China, the Americas and Europe. On a calculation recently made by the Bureau of Economic Information from an estimate of the Yokohama Specie Bank for 1925 the aggregate total reaching China from this source in various forms amounts to about

\$160,000,000. This certainly more than counterbalances the swelling of the export figures by the net profits of foreign residents in China and of foreign shipping and insurance companies. But, important as this factor is, it does not seem sufficient to cover what the official returns describe as an "unfavourable balance," reflecting the present economic position of China. To quote the Maritime Customs' report on the foreign trade of China (1926): "one must conclude that the Chinese people are dependent on foreign countries for a very great quantity of goods which they cannot produce as yet, while their own products meet with a very strong competition by similar products from other countries in foreign markets." The heavy import of food-stuffs in a country so predominantly agricultural is particularly significant, for it is precisely by the export of these and of raw materials that most agricultural countries pay interest on the loans made by foreign capitalists to assist their industrial development. In the case of China many of these loans have been secured on railways and other national assets, with resulting political complications, and under the most favourable circumstances a long time must elapse before China can completely free herself from the entanglements which this indebtedness involves.

The organization of Chinese foreign trade is now entering on a new and momentous phase. By the Treaty of Versailles Germany surrendered her concessions at Hankow and Tientsin, and Russia, too, as a result of the World War, lost and later renounced her treaty privileges. At the Washington Conference (1921-22) the Nine Power Treaty on the Chinese customs tariff decreed *inter alia* "a general revision of the tariff, to make it a more effective instrument of revenue, with the authority to increase it in return for the abolition of *likin*." Under Resolution IV. of the Washington Conference, the Commission on Extraterritoriality met in Peking in Jan. 1926 and in September of that year the representatives of 13 Powers signed the report recommending that, when certain conditions were satisfied, the Powers concerned should relinquish extraterritorial privileges, on the understanding that their nationals would then have the right to reside, trade and enjoy civil rights in all parts of China. The British memorandum on China of Dec. 1926, the British communication to the League of Nations with regard to China of Jan. 1927, and the important speech on China by the British foreign secretary on Jan. 29, 1927, re-affirmed the intentions of Great Britain regarding the relinquishment of extra-territorial rights and the concession of tariff autonomy; a similar declaration on the policy of the United States was made by the secretary of State in the same month. With the establishment of the Nationalist Government at Nanking, claiming authority throughout China, the fulfilment of these pledges is now under discussion (July, 1929.) China was negotiating separate trade treaties with the various powers concerned and a new tariff, freed from the old restrictions, was being prepared. Many difficulties remain and not least those concerned with the special interests of Japan, but it may with some confidence be anticipated that in the near future China will recover her tariff autonomy in exchange for the abolition of the hampering *likin* duties, and that, subject to certain guarantees, the privileges of extraterritoriality and the system of treaty ports will be abandoned.

Transport Conditions and Communications.—For the most part freight is still moved in China, as it has always been, by human labour, with animals as supplementary carriers. The wheelbarrow and carrying-pole are the commonest means of transport for small merchandise. In north China wheeled vehicles, mostly the springless Pekingese cart, are used to a considerable extent on the sandy tracks, while in the centre and south the sedan-chair is still in evidence, and rickshas are in general use in and around the larger cities. The Tsin-ling mountain belt roughly defines the northern limit of the general use of water-transport, which in north China becomes subordinate to the cumbersome cart, drawn by horse, mule, bullock or mixed team. In the utilization of inland waterways no people have excelled the Chinese. The natural routes provided by the Yang-tze and its great tributaries and to a less extent by the Si-kiang and other rivers of south-east China bear an enormous amount of junk traffic, while

steam boats, large and small, are increasing, especially in the Lower Yang-tze. From an early stage of Chinese history the rivers have been supplemented by canals, the beginnings of the famous Grand canal, now largely derelict owing to the migration of the Yellow river, going back to the 6th century B.C. In central and south China the great bulk of inland trade is carried on by water-ways, and many millions of Chinese spend their lives in boats. At various periods of Chinese history, notably under the Yüan (Mongol) dynasty, extensive systems of "imperial" highways have been constructed, radiating from the capital, but these have seldom been kept in repair for long and now are mostly mere tracks. In recent years, however, the "good roads movement," launched at Shanghai in 1921 and strongly supported by the merchant class, has made considerable progress, and round many of the more progressive cities broad macadamized thoroughfares, capable of carrying heavy traffic, are being constructed. Motor services are coming into existence, the longest being that from Kalgan to Urga (700 miles). The gradual displacement of human by motor transport in the neighbourhood of great cities like Shanghai and Hankow which has already begun, and must involve important social consequences.

The programme of railway construction, which in the early years of the century was making fair progress, has been almost entirely held up during the period of civil war. The outstanding feature of the railway system, so far as it has been completed, is the concentration in north China and the lower Yang-tze valley with Peking-Tientsin as the base line. Thence diverge: (1) The Peking-Kalgan-Suiyuan-Paotowchen line (597 miles) which ascends the scarps leading to the high Mongolian plateau and is intended to develop the pastoral and potential agricultural resources of Inner Mongolia and north-west China. This line is notable as having been constructed and maintained by the Chinese without external assistance. (2) The two great trunk railways traversing the plain of north China from north to south. (a) The Peking-Hankow railway, whose route lies along the western border of the plain, will become, when completed to Canton, the north-south artery *par excellence*. From Wuchang opposite Hankow it has already been finished as far as Chuchow south of Changsha in Hunan, and work on the Canton side has been completed to Shiu-chow in the Pei-kiang valley, leaving for future construction the intermediate section through the Che-ling pass. (b) The Tientsin-Pukow railway running through the eastern part of the plain links Peking with the Shanghai-Nanking line and the lower Yang-tze valley. (3) The Peking-Tientsin-Mukden railway, traversing the coastal sill between the edge of the Mongolian plateau and the sea, joins the two great northern centres with the metropolis of south Manchuria and makes contact with the complex and rapidly expanding railway system of Manchuria. (See MANCHURIA.) In a few years there will be direct railway communication between Canton and Harbin and so via the Trans-Siberian with Europe.

The most important transverse line is the east-west Lung-hai railway which from the new port of Haichow in northern Kiangsu crosses both the north-south trunk lines and runs through Suchow and Kai-fêng to Honan-fu and Ling-pao in western Honan, its present terminus. Apart from small branch lines, mainly tapping coal-fields, there are two important railways connecting with the main systems: the Shantung railway joining Tsinan-fu with Tsingtao (Kiao-chow) and the Shansi railway linking the Peking-Hankow line with Tai-yüan-fu.

Shanghai is the focus of a distinct system:—(1) Shanghai-Nanking (see above), (2) Shanghai-Hangchow-Ningpo, (3) Shanghai-Woosung (the first railway opened in China, 1876).

In the south, Canton has a similar role. Apart from the Canton-Shiu-chow line, already mentioned, short railways connect the southern metropolis with Kowloon, opposite Hongkong, and with Samshui. The only other important railway in China is the trunk-line, completed by the French in 1909, which runs from Haiphong in Tong-king to Yunnan-fu in south-west China, 200 m. of its course being in Chinese territory. There are short local lines running inland from Amoy, Swatow and Macao respectively, and one connecting Kiukiang and Nanchang.

Five provinces (Kansu, Shensi, Szechwan, Kweichow and Kwangsi) have no railway mileage, and several others very little. In all China (excluding Manchuria) there are about 7,500 m. of railway, or 1 m. of railway to 204 sq.m. of territory, as compared with 40 in India, 16 in Japan and 12 in the United States. Of the grand total about 73% is subject to the control of the Ministry of Communications and 27% is represented by concessioned railways. Among projected railways likely, if conditions are favourable, to be undertaken in the near future the most important are: (1) The completion of the trunk line to Canton on which the present Nationalist Government lays great stress; (2) the extension of the Lung-hai line westwards towards Sian-fu and Lanchow and, perhaps, ultimately into Sinkiang; (3) the construction of the long contemplated Szechwan railway, linking the great and remote western province with Hankow. It remains to be seen whether, now that the capital has been moved to Nanking, an attempt will be made to counterbalance the present railway centrality of Peking.

The postal service of China has been greatly improved in recent years and there are now about 12,000 post offices open and nearly 1,000 telegraph offices. As a result of the Washington Conference and in acknowledgment of the efficiency of the Chinese postal service, all the foreign Powers concerned agreed to withdraw their postal agencies from China on Jan. 1, 1923. Wireless is already fairly widely distributed, even as far afield as Urga (Outer Mongolia) and Kashgar (Sinkiang).

ADMINISTRATION

Since the revolution of 1911, which abolished the Imperial Office and the time-honoured machinery of administration, China has passed through a bewildering series of political changes and civil wars (see under *History*). A quieter phase has now supervened and constructive forces are obviously at work, but the factors in the political situation are still extremely complex and the legacy of militarism, which the civil wars have bequeathed, increases the difficulty of administrative reconstruction. A Constitution has recently been promulgated (autumn, 1928) embodying certain principles to which, in theory at any rate, all Chinese Nationalists adhere and the outlines of a new system seem to be appearing. It would be rash to assume that its foundations are stable or that there is any finality in the present arrangements. None the less they exhibit certain tendencies which will probably have a greater degree of permanence since they reflect the mental attitude of a large section of the educated class. The new Constitution and the administrative arrangements which it contemplates are the work of the Kuomintang or People's Party, which is not only supreme in China but is the only party whose existence is recognized. Dr. Sun Yat-sen, the founder of the Kuomintang, has since his death been regarded in some sense as its patron saint and his will or statement of three essential principles is regarded as a kind of instrument of government. It is far too long to be quoted *in extenso* or even summarized here, but certain features of it, especially those which have a direct bearing on the new Nanking Constitution, may be briefly noticed. The "three principles of the people" have been translated as:—

- (1) Nationalism ("National emancipation and racial equality").
- (2) Democracy ("Political rights for the people").
- (3) Socialism ("Economic rights for the peasants and workers").

Under the first principle ("Nationalism") Dr. Sun states what is necessary for the development of a strong national consciousness so that China can escape from the position of being "a colony of every Great Power." One of the steps on which he insists is that "we must organize our people into one strong organic group. This can be accomplished only by utilizing such strong units as clans and local organizations." Many old characteristics must be revived, including "our old learning as found in the *Great Learning*" and "we must revive our creative power, the power which we once had in inventing new things." He adds "we must do all these things, but, aside from that, we must also go out to learn what is best in the West." Under the second principle ("Democracy") Dr. Sun first states the case for democracy and maintains

that China in this respect has little to learn from the West, since "the West has, in the last century, progressed much more rapidly in material things than in those that concern man and his welfare. In politics, very little advance has been made." He makes the interesting point that whereas the Western peoples had formerly too little personal freedom and had to fight hard for liberty, in China "our people have had too much personal freedom" and, as a result, "have become a plate of sand . . . helpless in the face of foreign imperialism and its economic conquest." "So what we need now is not to fight for more personal freedom, but to sacrifice some of our personal freedom, in order to gain our national freedom." China has to face two problems, in the solution of which, he maintains, she is helped neither by her own nor by Western experience: how to have a strong central government and at the same time to remove the fear of the people of such a government. To build up a powerful Government machinery and to enable the people fully to exercise their power and control of the machinery two things are essential: (a) The organizing of government "on the five principles—legislative, judicial, executive, entrance to public office by examination, and censorship"; (b) safeguarding the people with "the power of election, power of recall, power of initiation of new laws, and power of revision or abolition of old laws."

Under the third main principle ("Socialism") Dr. Sun insists that "we must centre all our problems around the welfare of the people" and avoid the Western mistake of taking "material problems as the central point in human history." "None of the forms of Socialism developed in the west are fitted for our own country." China has to avoid the dangers of industrialism. "Our great and immediate problem is not economic inequality but economic poverty, not a fight against capitalists, but the prevention of the rise of capitalists in the future. Our method of solving this problem is to develop State industry." He enumerates a series of measures for increasing production and concludes: "on the one hand there is an urgent need of improving our old methods of raising raw materials. On the other hand, we have to develop our own textile industry as rapidly as possible. This is at present hindered by the treaties which forbid us to have tariff autonomy. So our first step in solving the problem (of clothing) is to remove all unequal treaties so that we may carry out a policy of protection."

The official programme of the Kuomintang, passed at a plenary session of the central executive committee, with delegates from all provincial committees, in Oct. 1926, at Canton, is essentially an elaboration of the main points and an application of the abstract "principles" contained in the famous will (the quotations cited are from the translation of Dr. Sun Yat-sen's will given in an appendix to Sir Frederick Whyte's *China and Foreign Powers*. The same appendix contains the programme of the Kuomintang).

The administrative areas (1931, Jan.) include 28 provinces, namely, Kiangsu, Chekiang, Anhwei, Kiangsi, Fukien, Hupeh, Hunan, Kwangtung, Kwangsi, Szechwan, Kweichow, Yunnan, Shantung, Honan, Hopeh (formerly Chihli), Liaoning (formerly Fengtien), Kirin, Heilungkiang, Shansi, Shensi, Kansu, Sinkiang, Hsikiang, Chinghai (or Kolonor), Ninghsia, Suiyuan, Chahar, Jehol and five special municipalities under the control of the Executive Yuan, namely, Nanking, Shanghai, Tientsin, Hankow, Tsingtao. There are in addition two special administrative districts, namely, Eastern Provinces special district (Chinese Eastern Railway zone) and Wei-hai-wei. The provinces are subdivided into 1915 districts and 11 municipalities.

The actual framing of the Constitution, in accordance with the theoretical aims which have been briefly surveyed, has been conditioned both by: (1) divergence of view as to the interpretation of the doctrines, since within the Kuomintang are both conservative and extremist groups; (2) The power of the great military chiefs and groups who assisted in the triumph of the Nationalist party. The organization of government is as yet (Dec. 1930) by no means complete. Historic divergencies between the North, the Yang-tse-kiang Basin, and the South break out when the central power is weakened and these differences, combined with rivalries of Tu-chuns or Provincial Governors, are important sources of difficulty. Late in 1930 a Manchurian War Lord, Chang-hsieh-

liang, assumed control of Peking and the northern provinces. The Constitution gives the views of the moderate or conservative side of the Kuomintang to which the "Kwangsi party" is opposed. The following are the chief features of "the organic law of the National Government," as ordained by the Kuomintang:—

1. A government council consisting of not more than 15 members, vested with supreme power. It is to control the army, navy and air force and is alone competent to declare war, conclude peace and negotiate treaties with foreign States. Its chairman is the official head of the State, representing the nation in international affairs, and at the same time is commander-in-chief of all the forces.

2. Five *yüan* (or councils) for the following functions:—executive, legislative, judicial, examination and control (i.e., censorship or supervision). Of these the executive *yüan* is the highest organ of the national government "and shall establish Ministries to which will be entrusted various executive duties." The presidents and vice-presidents of the five *yüan* are to be appointed from the government or state council, which shall also settle disputes arising between the *yüan* themselves. It will be observed that the five *yüan* or councils are in accordance with Dr. Sun's proposals under his second essential "principle." The control or supervisory *yüan* revives the functions of the censorate under the Imperial régime. So too is revived the system of public examinations as the test of admission to public office, and a special *yüan* comes into existence to supervise it, but whereas in the old days the State was concerned only with the conduct of examinations, it is now responsible for a national system of education. This, indeed, has been in existence for several years, and notwithstanding the dislocations caused by the civil wars, has made considerable progress. The system, first established during the last years of the Manchu dynasty, has been twice re-organized under the Republic, first on the Japanese and later on the American model. It now consists (subject to revision by the Nanking Government) of:—

1. A six-year primary school course (covering approximately the ages six to twelve) divided into two grades: lower and higher primary, each of three years duration. In theory this is obligatory, but only in one or two provinces has the ideal as yet even approached realisation.

2. A six-year middle or secondary school course (12-18), similarly divided into lower and higher grades, the higher tending to be vocational in character.

3. A four-year university course. In some cases there are industrial higher primary and middle schools, which are parallel and alternative to those mentioned above. There are also normal schools both lower and higher for the training of primary and middle school teachers respectively, and also higher professional or technical colleges of various types.

The educational programme of the Nanking Government contemplates a revision and extension of this scheme and the devotion of a high proportion of public revenue to the schools and colleges. Two new features are the introduction of military training and the compulsory registration under Chinese law of all missionary schools and other schools established by foreigners.

While the machinery of the Government has thus been "ordained," that part of Dr. Sun's programme which indicates popular control through "power of election" and "power of recall" has yet to be worked out, and it is precisely on this subject that the differences between the moderates and extremists are most acute. Presumably the local branches of the Kuomintang will choose representatives for provincial assemblies and from these the delegates to a national "parliament" will be selected. The extent to which the Kuomintang local branches can be related to the existing village and clan organizations may be a question of great importance. The system of village government by the council of elders, with the *Hsiang-chang* (village headman) as its elected representative, still survives and is perhaps the most important legacy of the old China. Revolutionary as he was, Dr. Sun had certainly a real respect for the ancient institutions of his country and desired, as some of the quotations which have been given from his will suggest, that the new organization should spring from the old

foundations. It is indeed difficult to imagine that any political superstructure can be stable or command for long the confidence of the people unless it rests on the system of local self-government which has been from time immemorial the bedrock of Chinese society.

ETHNOLOGY

Although man probably existed in China before or at the beginning of the deposition of the loess (*see* CENTRAL ASIA: *Racial History*) there is at present no certain evidence of palaeolithic man in China. Two specimens have been found which have been considered to point to early man. A sacrum, undoubtedly human, was found in Honan, and described by Matsumoto, who failed to realize that its characters were rather akin to those of the modern Chinese. In 1921 Dr. Andersson discovered in a rich fossiliferous deposit at Chou Kou Tien, south-west of Peking, a number of specimens including a premolar and a molar tooth. Black considers these to resemble in general form a fossil molar or "dragon's tooth" bought in Peking by a German palaeontologist called Schlosser. Fossil bones ground to powder are much

used as medicine by Chinese and no data appear to be forthcoming as to the origin of Schlosser's specimen. While Black is convinced that the teeth represent "archaic hominid fossil material," other palaeontologists are less certain and the matter still awaits definite confirmation.

Apart from these doubtful specimens nothing of remote antiquity has been found in China. The earliest discoveries by the people themselves of whom there is definite knowledge are associated with the chalcolithic culture, and although differing in some respects from modern Chinese, are of essentially the same racial stock. Traditionally the Chinese are said to have come from the Tarim basin and to have spread down the valley of the Wei Ho into the great plain. Their extension into southern China is a matter of recent history and is still proceeding. While the cultural evidence for this extension seems to be satisfactory, the racial characters of the chalcolithic skeletons make it possible that the Chinese claim to have come from outside China and to have driven out the barbarians, some of whom still lingered even in Honan until recent times, may not be so true racially as it is culturally. In any case the oldest culture known in China, and it probably is not of a very early date, shows affinities with the West, while the people living in China at that time were like the Chinese to-day; on the other hand the Mongols, whose culture is entirely alien to the Chinese, are physically akin to the peoples of the West.

The true home of the Chinese, whatever their original centre of dispersion, seems to be the basin of the lower Hwang Ho; but they have dominated, racially and culturally, both the original 18 provinces, and Manchuria, Korea, and to some degree Japan. There seem to be two physical types, a northern and a southern, though the differences between them are not very great, the northerners being generally somewhat taller.

These northerners themselves probably consist of a blend of two minor types, one akin to the Kham Tibetan—tall, long-headed, big-boned, mainly proto-Nordic in origin. The second stock is similar if not identical with the southern Chinese, who are smaller and more roundheaded. They represent that branch of Yellow Man designated "Pareoan," meaning the people from beside the dawn. It is probable that there is in China a mixture of many stocks; not only have the Chinese invaded aboriginal territory and absorbed the inhabitants, but China itself has been

A CHINESE WEDDING, WITH THE BRIDE WEARING A SEMI-OCCIDENTAL DRESS

continuously invaded especially from the north. The skin colour is generally light yellow, the hair is dark and straight. The Mongolian eyefold is conspicuous. The stature is medium and the head-form ranges from long to round; the nose is of medium width. Here and there are fair, light-eyed, wavy-haired groups, evidence of the alien stocks which have penetrated into this area.

Social Organization.—The basis of Chinese social organization is a closely knit and highly organized family. The house father is directly responsible for all who live under his roof, including his wife and unmarried children, his married sons and

their wives and children, his servants and probably other dependents. He is personally responsible for the economic and moral welfare of this miscellaneous group, which includes on an average between five and ten persons, and is liable legally for their misdemeanours. This system spreads upwards. The official was held to be the "father and mother" of his people, and the emperor was himself directly the head of a patriarchal family, the Chinese nation, for whose welfare and the success of the crops he was directly responsible to heaven. Much of the cohesion of China is due to this amazing social system, though it tends to exalt the family at the expense of the State. Owing to the necessities of ancestor worship the raising of male progeny is a sacred duty of every Chinese, a fact which may account for the early marriage and the large number of children. Polygamy is permissible, but it is naturally a luxury of the wealthy rather than a general practice among the poor. Marriages are arranged by the parents of the prospective couple, but secondary marriages are usually "love matches." Where no sons are born the practice of adoption is used, both among rich and poor. By the rule of exogamy marriages were forbidden between persons bearing the same family name.

BY COURTESY OF THE BOARD OF
FOREIGN MISSIONS
A MANDARIN IN OFFICIAL
ROBES

With the exception of a few families, notably the descendants of Confucius, China has no aristocracy. Position depended entirely on success in the great examinations for literary degrees, from the successful candidates of which officials were chosen. Side by side with the official class there has always been a merchant class enjoying the advantages of wealth. The levelling effects of dependents have probably contributed much to these democratic conditions. The higher a man pushed himself up the more numerous became his household, and it was a necessity under the old Chinese system that a magistrate should never hold office in his own province, otherwise his duties to his family would have outweighed his official duties.

Religion.—The three great religions of China are Confucianism, Taoism and Buddhism (*q.v.*). The special feature of local religion is ancestor worship, though Taoism incorporates much that belongs to primitive religions. In China the dead form an important part of every household. A third son is always a third son, even if his elder brothers are dead. The head of the house, living or dead, is always the head of the house. To his tomb his descendants come, and they have mortgaged much of their scanty acres in erecting grave mounds which must never be ploughed till the family is forgotten. Against such a calamity every precaution is taken by adopting children when sons fail.

In addition to the worship of ancestors, which overshadows even the food quest in China, geomancy and other forms of magic play an important part. It is necessary for every enterprise, old or new, that it should possess the necessary *fêng shui*—literally "wind and water"—roughly "luck." Considerable opposition has often been raised to the building of railways and other foreign inventions because perhaps a certain cutting might disturb the spirits and so spoil the luck of a city. Fortunately, spirits particularly like a valley girt about with hills, and to this we owe the preservation of such lovely pieces of scenery as the tombs of the Ming emperors near Nankow.

The Chinese are much addicted to the *sortes* and will cast lots before undertaking any enterprise, throwing down two pieces of bamboo root till they turn up in a favourable manner.

Buxton, *The Peoples of Asia* (1925); J. Mallory, *China the land of famine* (1926); S. King, *Farmers of Forty Centuries* (New York, 1927).

Aboriginal Tribes.—Chinese men of letters have classified the aborigines of China in a four-fold artificial manner, calling them by names which are more or less the equivalent of the Greek *barbaros*. It is probably more correct, however, to divide

them into three groups, the Miao, the Lolo, and the Chung Chia. Their distribution is approximately as follows: there are Black Miao and Chung Chia in Hunan, and the city of Chung-teh, near Tungting lake records the presence of aborigines in its neighbourhood. The Chung Chia extend across the border into Burma, where they are known as T'ai (*q.v.*). The Black Miao live north of these peoples. The two classes of Flowered Miao live in west-central Kweichow, and north-eastern Yunnan. Originally their distribution was probably much wider. Physically all these peoples seem to represent an intermediate type between the long-headed peoples of the Near and Middle East and the Nesiot of south-eastern Asia. They are all mixed to a greater or lesser degree with Pareoceans. Culturally they are mostly agriculturalists, but everywhere they have been much affected by the surrounding Chinese.

ARCHAEOLOGY

The study of prehistory in China is particularly difficult owing very largely to the geographical structure of the country. Three areas may be enumerated, the great prairie region, which includes much of Mongolia and part of western Manchuria, northern China, including the great plain and the lowlands of Manchuria, and thirdly, southern China. This latter region, which is in the main extremely mountainous has at present been little studied archaeologically, and its prehistory is almost unknown.

Thus there are many gaps in our knowledge, but none the less great credit is due to those explorers who have contributed the knowledge which we already possess. In the northern region the country is sparsely inhabited mostly by wandering nomad tribes. Distances are great and, except on the borders of China proper, few discoveries can be made without the aid of elaborate expeditions such as that of the American Museum of Natural History, which discovered the Dinosaur's eggs in Gobi, and has already found abundant traces of Neolithic man in surface deposits. The southern part of this region and nearly all northern China is covered with fine wind-deposited loess. The discoveries of Pères Licent and Tielhard make it probable that the remains of early man are hidden beneath this yellow covering, which is so thick in some places that exploration is impossible except where the loess has been cut through by the action of water in river valleys, and the older strata have thus been exposed. Such canyons in the loess have proved in a few cases to be most fruitful. In the plain itself, however, these deep river valleys are non-existent for the streams run at a level which is actually higher than the plain. All along the fringe of the plain there are found the natural conditions necessary for the formation of deep valleys. The mountains of northern China also possess caves, so fruitful a source of finds for the prehistorian, which though so far only productive of a somewhat recent culture, offer promise of important discoveries.

Sites.—The Palaeolithic sites so far discovered fall into three groups, all of them in the north. The first site is situated in the south-west corner of the Ordos bend of the Hwang Ho (Yellow river), and is called from a central spot *Shuitungkou*. The ancient floor of the principal site is about 18 in. thick, and between 3 and 6 ft. above the conglomerate at the base of the loess. The inhabited site is about 60 ft. long. No human bones have been found but the ground was literally strewn with implements and there were a very large number of animal bones, undoubtedly kitchen refuse. The bones belonged principally to the wild ass and possibly a horse, the woolly rhinoceros (*Rhinoceros tichorhinus*), *Bos primigenius*, gazelle, hyena and a type of ostrich (*Struthiolithus*) whose egg-shells are abundant in the loess. The implements, most of which are worked on one face only, are usually of considerable size. They show little refinement of technique and are mostly rather crudely made. Their abundance and form can be explained by the nature of the material at hand. There are plentiful supplies of flinty stone, of a rather coarse grain, which does not allow careful or exact workmanship.

This crude character and large size of the implements found are of considerable importance in making comparisons with other sites. The implements are difficult to place typologically. The majority suggest an Aurignacian industry, others are more reminiscent of the Magdalenian. The comparison between the finds made at the type site and on other hearths in the neighbourhood, at different levels, suggests that the area was inhabited by palaeolithic man for the greater part of the time during which the loess was in the process of formation.

The second series of sites in the Ordos country is different from *Shuitungkou*. Finds have been made along the course of the Sara-osso-gol. This river, which is a tributary of the Hwang Ho, flows from the loess-covered mountains of the province of Shensi and traverses the south-eastern angle of the Ordos country. It has cut a ravine which is sometimes over 200ft. deep. The sides of this ravine show clearly the succession of strata which have filled up the basin which formerly existed in this region at the beginning of quaternary times. Man lived on an old floor and since Palaeolithic times there has been the following succession of strata. First, dunes accumulated over the old floor, then a lake, then new dunes, then there was a new lake, until finally the level of the modern steppe was reached. Neolithic finds have been made in the black soil at the top. In the levels associated with the presence of man the fauna is extremely rich, but implements are small and infrequent. The fauna in many ways resembles that from *Shuitungkou*. The woolly rhinoceros is very abundant, remains of elephant were found, probably *Elephas nomadicus*, not the mammoth (*Elephas primigenius*). The wild ass and *Bos primigenius* also occur, while gazelles abound. Numerous antlers of deer were found, apparently used as some form of weapon or tool. A very large camel also appeared. The big and small animals found in this deposit are in great contrast. The small mammals are without exception the same as those found to-day in the same regions. Among the big animals many types are represented which have either become totally extinct or are no longer found in the same area. These large animals show remarkable affinities with the fauna of Europe in Middle Quaternary times, and appear to have had a wide extension over northern and central Asia at the time of the formation of the loess. The implements are extremely small and present unusual forms. The largest implement is under 3in. long. This implement presents a close parallel to some of the scrapers from *Shuitungkou*. Similarly some of the smaller implements from that place suggest the Sara-osso-gol specimens. It seems probable that we are not dealing with different cultures. The Sara-osso-gol neighbourhood is singularly deficient in any form of pebbles and it is probably due to this geological condition and not a difference in culture that the explorers of the site were only able to collect a mere handful of implements, whereas on the other site their finds ran into many pounds weight. The Sara-osso-gol culture appears to have had a wide extension in space. At present no implements have been found in the strata above the Palaeolithic. There is therefore a complete absence of any form of transitional period between the Palaeolithic age and the surface Neoliths.

The Palaeolithic industry has also been studied by the same authors in the loess of northern China. Owing to the rapid erosion to which this soil is subjected this has been possible, and two principal sites have been examined, *Kingyan* in Kansu and *Yu-jengtou* in Shensi. All these sites probably belong to the same period, that is the base of the loess.

The distribution of the finds so far made is restricted to the southern part of the Ordos country, the north of eastern Kansu, and the north of Shensi. Nothing Palaeolithic has been discovered either in eastern Gobi or beyond the north-western border of the Ordos country, possibly due to the fact that the correct strata have been eroded, but it is curious that animal bones have been found in deposited strata. In the more southerly regions no thorough search has as yet been made in those places where the base of the loess is exposed.

The chronology is as yet uncertain, a comparison of the fauna and of the types of the implements suggests that probably this

early culture was approximately contemporary with the Mousterian and the earlier part of the Aurignacian period. The importance of the finds depends on several factors. First they show that the Palaeolithic industries spread right across the Eurasian continent, indeed some of the implements show analogies with implements found by Buxton in the north Arabian desert. Secondly, the finds at the base of the loess suggest that man was inhabiting China at a period before the deposition of that great yellow covering which is to-day the most characteristic feature of that country. The finds also help to throw light on the date of the loess.

The remarkable character of this culture is its apparently abrupt ending. The old floors are clearly defined. There are other strata superimposed upon them, but no traces of human handiwork between the Palaeolithic and the Neolithic have so far been discovered *in situ*. Up to the present the Mesolithic, *i.e.*, the age between the Palaeolithic and the Neolithic is entirely absent with the exception of certain finds in Gobi. Nelson, a member of the staff of the Third Asiatic Expedition of the American Museum of Natural History claims to have discovered certain implements on the surface of the desert which are Azilian in form, but as they are unrelated to any definite stratigraphy it is not possible at present to express any definite views on them.

Implements from other parts of China have also been claimed as being either Palaeolithic or Mesolithic but a closer examination has failed to substantiate the claims put forward, although at first sight some of them do bear a close resemblance to Palaeolithic implements.

Neolithic Remains.—The remains of the Neolithic period are widely scattered over the whole of China and Mongolia. Surface finds have been made in many provinces. In the extreme south, in the province of Kwangsi, which lies to the west of Canton, stone axes are said to be very commonly found. Associated with them is the folk tale, so widely spread over the world, attributing their origin to thunderbolts, and indeed in one region they are said to be particularly abundant near the temple of the Thunder God. A similar story, associated with finds of numerous Neolithic axes, also comes from Yunnan, the most south-westerly province of China. Grooved stones for polishing axes have also been reported from Kwangsi. Few reports have been made of finds from the central provinces of China, but specimens, undoubtedly Neolithic, exist in private and public collections in Shanghai.

Far the richest finds have been made in the north. The Gobi region and much of north-eastern China and Manchuria have proved to be extremely rich in Neolithic remains. Surface finds are extremely abundant over most of the whole region. In some cases, especially in regard to arrow heads of stone there may well be some doubt as to their age, as the Chinese were well aware of the use of these implements, which may have continued to serve barbarous tribes until well within the historic period. In certain parts of Mongolia, however, implements have been found *in situ*, not as surface finds, and can therefore be definitely dated.

The Neolithic implements nearly always occur in a bed of black sands, from 3–12ft. deep superimposed on the Quaternary sands, which in Mongolia replace the Chinese loess. The Neolithic here appears to succeed the Palaeolithic without any transitional period and is very widely spread. One of the most remarkable sites so far explored is at *Linsi* (approximately 116° E. 44° N.). Here most of the implements are extremely rude, not unlike those of Palaeolithic date, but some fine and very delicately worked implements were also discovered. A few grindstones were found but no green polished celts. The pottery is very rude and was not made on a wheel. No painted pottery has been found on these Neolithic sites. Among the finds at *Linsi* certain flattened pear-shaped implements were found, and a similar instrument was obtained by Andersson at *Kalgan*. These stone implements are very important. Not dissimilar implements occur in other parts of Asia, but the closest parallel is North America. There can be little doubt that they were rude ploughshares and it is possible that they form another link between north-eastern Asia and North America. In any case there is every reason to believe

that this Neolithic culture was extremely widely spread over a wide region in the Far East.

Some of the finds suggest that climatic changes have taken place since the Neolithic Age. If the implements are, as suggested above, really ploughshares some at least come from regions which to-day are devoted to pastoral nomadism, and the presence of agricultural implements suggests that in Neolithic times the climate was somewhat different. Further, quite a large number of Neolithic implements have been found in regions which to-day are extremely poor steppe. They may be the remains of a merely temporary occupation, but the evidence is at least suggestive of a considerable change in climate.

Chalcolithic Remains.—These finds, Palaeolithic and Neolithic, represent but the beginning of discovery. The most revolutionary discoveries in prehistoric China are those made by Dr. Andersson of a culture which, though it may be termed Neolithic, because on most sites there is an entire absence of metal, more properly belongs to the transitional period between stone and bronze which is termed by archaeologists "Chalcolithic."

Dr. Andersson's finds cover a wide area, extending from the extreme east to the extreme west of China. The most easterly site is a cave at Sha Kuo T'un, in the province of Fêngtien, of which Mukden is the capital, in Manchuria. No Chalcolithic remains have as yet been found in the metropolitan province of Chihli, of which Peking is the principal city, but to the west a site has been discovered at Paotê in Shansi, at Fuku in Shensi, and finally abundant remains of a Chalcolithic culture have been found in Kansu, the province which lies in the extreme north-west of China. Thus sites have been found all along the northern border. To the south at present only one province, Honan, which lies in the very heart of China, has yielded any results. Here four sites have been explored, Yang Shao Tsun and Pu Chao Chai, in the district of Mien Chih, Ching Wang Chai and Chih Kou Chai in the district of Ho Yin.

The site at Yang Shao Tsun in Honan occupied a very big area, being over 600yd. long and about 500yd. broad. The deposits which are nearly 10ft. thick are slightly covered by arable soil. The stratum on which the remains rest has been in places excavated into large pits, often as much as 6ft. deep and of the same width. The deposits consist mainly of a mixture of soil and ashes, and apart from a few graves contains mostly the débris of an inhabited site. The fauna of the site has not yet been published in detail, but apart from the porcupine it does not appear to include any interesting wild animal. As in modern China the domestic pig appears to have been abundant.

The finds in Fêngtien province in Manchuria were made in a small cave close to the railway between Tientsin and Mukden, about half way between those two towns. The cave was only about 20ft. long and 10ft. broad. It contained, however, over 6ft. of deposits, which consisted of a filling of clay alternating with three bands of charcoal which were extremely rich in ancient remains. In a layer, about half up, of broken and calcined human bones Black recognized the remains of about 45 individuals. Apart from differences in the implements due to the available raw material there is no reason to doubt that the Honan and the Fêngtien sites belong to the same culture.

In Kansu, Andersson has explored certain parts especially in the west of the province round the city of Lanchow. He has found numerous sites, both inhabited and burying places. On the basis of the pottery he has grouped the sites into different sub-periods of which the three lowest correspond to the sites from other parts of China, whereas the upper ones appear to belong to the Copper or early Bronze Age. The pottery from Kansu is both abundant and of very fine workmanship, whereas the implements are both poor in workmanship and relatively infrequent. The best pottery has been found in the graves. Most of the bodies were found extended, the head being turned towards the north, but in two graves the skeletons had been placed on the left side in a contracted position. A large number of the bones were covered with red ochre.

At present no exact information appears to have been published on the associated fauna, but the domestic pig appears, as in the

other sites, to have been extremely abundant.

Except for the sites in Kansu no metal has as yet been found on any of these sites. Either the people were unacquainted with the use of metal, or alternately, and less likely, metal objects have so far escaped the eyes of the excavators. The artifacts may be divided into three classes, stone objects, bone objects and pottery.

Stone Implements.—The implements made of stone show a considerable variety. First there are rough implements made of chert or chalcedony. Many of these implements are very rude in form. Secondly there are a large number of stone celts and other axes and chisels. Some of the celts are very flat in section, recalling in many ways some celts from America, but this resemblance is possibly due rather to the material out of which they are made than to any real relation. The arrowheads which have been found present certain features of interest. Torii in reports on early sites in Manchuria thought that he was able to distinguish between two types of arrowheads, which he called Manchu and Mongol respectively. The Manchu type is made of slate or some similar material and is polished. The Mongol type, on the other hand, is of chalcedony and is flaked. The two types both occur in the Chalcolithic deposits, the flaked arrowheads occur in Manchuria, while the so-called Manchu type is found on the ancient sites in Honan on which only one flaked implement was found, an extremely important obsidian knife. Andersson regards the difference between the two types as probably due not to any ethnological differences but to the different varieties of material which could be obtained. In any case the arrowheads are of little value for archaeological purposes because as late as the T'ang dynasty which ruled China from A.D. 618–906 there are records that arrowheads of chalcedony were given by some of the tribes of Manchuria to the emperor of China.

Rings of stone and of mussel shell were also found. Their meaning is somewhat obscure. They may have had a magico-religious purpose. Parallels to such stone rings can be found in various parts of the world, but at present they have not been sufficiently studied to throw any light on this intricate problem. Bone needles and awls have been found by Andersson in some abundance. One he believes to be almost identical with a specimen from the Danish kitchen-middens. The resemblance was probably due rather to the limitations imposed by the material than to any actual cultural connection.

Pottery.—The pottery forms the most important element in the finds from the scientific point of view, is of great beauty and from the technique employed shows clearly that the makers must have been the inventors of, or the heirs to, a comparatively advanced civilization. Some of the pots are somewhat crude and undecorated, and may be paralleled by Torii's finds in Manchuria. This crude pottery may be local ware, possibly surviving from the true Neolithic period and widely spread over the Far East. Such survivals of old wares for domestic purposes are by no means uncommon, just as other tools, or the use of stone for implements, may survive long after the culture with which they were originally associated has been superseded by a more advanced civilization.

The most characteristic pottery, however, from the Chinese sites consists of a very fine ware decorated with painted designs. In some cases the surface of the pot has been treated with a fine washing of clay, technically known as a slip, before the paint has been applied; in other cases the paint has been put direct on to the finished surface of the pot. The colour of the paint is usually either red or black and red. An examination of the fabric of the pots has shown that they are the product of a relatively advanced industry. They are made of a loess clay, the most readily obtainable material in northern China, which is not available south of the Yangtze Kiang; so that future finds south of this river, even if of the same culture, are likely to differ in technical details. The clay has been very well washed and freed from plant remains and other impurities, and probably worked into a paste. To this mixture some quartzite or other flinty material was added to give strength to the pot and to prevent it collapsing during the process of manufacture. Some of the wares are of different colours. These differences are due to the amount of iron oxide

and to various degrees of burning. It is probable that the addition of iron was made in order to affect the colouring, and possibly also the potters were able to control the firing, but on the whole these differences, striking as they are, must be considered largely as the result of semi-accidental factors. The classification by colours is therefore not an essential feature. The nature of the ornament is quite otherwise.

Ornamentation.—Two main types of ornaments may be distinguished. In the Kansu ware there are various more or less realistic paintings of animal form, or, more technically, zoö-morphic. The sherds and pots from the more easterly and southerly sites, on the other hand, are conventional or geometric. These ornaments consist of spiral bands and lines, of triangles, often fantastically exaggerated, of circles, sometimes single, sometimes concentric, and of discs, *i.e.*, circles whose interior has been filled in to form a solid. A kind of lattice pattern is extremely common, and is used either as a band all round the pot or as the filling of a triangle. This lattice ornament and the spirals are the most characteristic. In the Kansu finds an interrupted and a continuous Meander pattern is also found.

Most pottery was made on the wheel and the firing was carried out with considerable skill. The forms can seldom be reconstructed owing to the fragmentary condition in which they were found, but at least three classes appear to be represented. The painted pottery includes, first, bowls, which are either hemispherical or rather flat and basin-like. Secondly, there is a group of tall pear-shaped pots. These have a comparatively narrow base and gradually increase in size for about two-thirds of their height, after which they again decrease in diameter, but are provided usually with a projecting rim. The unpainted ware includes a series of tripod jars of considerable interest. A vessel which probably had a narrow neck like so many water pots used in the East to-day was also found, but the exact shape of this vessel is uncertain as it was much broken. Pots with pointed bottoms have also been found.

Tripod vessels are not uncommon in south-eastern Europe and occur as early as the first city of Troy. The pear-shaped vessels show an undoubted analogy with similar pots, sometimes painted, sometimes plain, which have been found in the Danube-Dnieper region, although there are certain differences in the form of the rim. On the other hand the small bowls show affinities with others found at Anau and Susa, in the earliest strata on those two sites (Anau I. and Susa I.). The pots with pointed bottoms have a wide distribution, and parallels could be cited from Troy, Egypt, and even India, and therefore provide little evidence for the solution of the real connection of the culture. A further parallel with Troy is, however, found in a pot with a perforated bottom, a type of pot also found in Persia and Egypt. At present, parallels with other regions of the Far East are lacking, but some of the objects from Manchuria, described by Torii as pottery handles, may turn out to be the legs of tripod pots.

The decoration on the pottery throws further light on the problem. At a date which probably coincides with the 3rd millennium B.C. (though there are divergent opinions on this question) the use of painted pottery was widely spread over south-eastern Europe and western Asia. The technique is similar, but certain differences in design have led some writers to question the association of all the Chinese finds with those of the West. There can be no doubt on general grounds that all the pottery belongs to the same family and that it has a very wide distribution in Eurasia, at the period covering the transition from the Stone to the Copper and Bronze ages. Although the distance is very great there are no marked geographical boundaries except deserts in the region which stretches from the Aral-Caspian basin to the Pacific Ocean. There have been trade routes across this region from time immemorial and there is reason to believe that in former times the deserts did not constitute the barriers which they do at present owing to different climatic conditions.

In the extreme West, painted pottery has been found on various sites in south-eastern Europe, namely at Tripolje (in south-west Russia), at Petreny (in Bessarabia), at Schipenitz (in Bukovina), and on various other sites in Transylvania, Galicia and Moldavia.

The painted pottery penetrates as far south as Thessaly and had a wide distribution over the whole of the area mentioned. Both in form and in the types of decoration the Chinese ware is very suggestive of this Danube-Dnieper culture. The pottery of Asia Minor on the whole is less reminiscent of the Chinese ware, but elsewhere in western Asia close parallels can be found.

Main Parallels.—Two areas are important, a northern and a southern. In the north Pumpelly conducted excavations at Anau near Askabad in Turkistan in 1904. He found four different cultures called respectively Anau I., II., III., IV. The last culture was of Iron Age date. In the earliest period copper was relatively rare, but pottery was abundant, and the pots were hand made, painted, often polished and decorated with geometrical designs. In Anau II. copper is abundant, but most of the ware is monochrome. It is therefore mostly with Anau I. that parallels with the Chinese pottery must be found. There are certain agreements; lattice work designs are common to both and in the straight-line patterns there appears to be a close parallelism. At Anau, however, curves are very rare and circles do not occur. There is therefore a disagreement in what appears to be one of the most marked characteristics of the eastern Chinese ware. Pots which resemble the Anau I. have been found near Nachitzewan in Transcaucasia, a site which can be dated at probably about 2500 B.C., and the artifacts in which represented a highly developed Copper Age.

In the southern area parallels can be found with the Chinese pottery in Mesopotamia, Persia and Baluchistan. The Persian sites include Susa, the capital of ancient Elam, and the mounds of Pusht-i-Kuh, about 100 m. west of Susa, the most important site being Tepe Mussain. The earliest pottery from Susa may be divided into two classes, of which the first and most ancient shows certain resemblances with the eastern Chinese pottery, but it should be noted that copper implements are found in all strata at Susa. A closer parallel is found, however, at Tepe Mussain, which in date probably coincides with the transition from Susa I. to Susa II. In the pottery from this site all the motives are found which occur in the eastern Chinese pottery, except the meander, which is limited to the finds from Kansu.

The finds of painted pottery from Mesopotamia, notably at Kish and Jemdet-Nazr by Langdon, in the north and by Campbell, Thomson and Woolley in the south provide the necessary link between Anau and the Persian sites.

The pottery from Baluchistan, published by Noetting, resembles very closely the Honan pottery, and indeed is closer to it than any other of the western material except possibly some of the Mesopotamian wares.

Links Between East and West.—These parallels, however, striking as they are, are by no means conclusive. At present the links between China and the West have not been fully established. There is a unity between the Persian and the Caucasus region, but between this area and China there is a long gap. Some suggest that the Honan finds should be considered as an early purely Stone Age culture and that China is the original home of copper working, which spread thence westwards. This seems unlikely. Secondly, others think—and Arne seems inclined on the whole to support this hypothesis—that there have been two great waves of immigration. The first was so early that either it did not bring copper with it or it became so quickly isolated from the West that the metal did not come through by means of trade. Arne also suggests that the presence of copper objects in the graves at Sining and Chênfan in Kansu may mean that this culture is somewhat younger. Frankfurt, on the other hand, believes that the painted pottery with a spiral design is a local growth, but suggests an analogy between the Persian ware and some of the finds from Kansu. He states that "some sherds recently found in China might suggest that the knowledge of copper-working perhaps also spread to the East from the Persian Caucasian region." He admits "significant indications" but considers the material too scanty for a definite pronouncement. The different views then appear to be: the origin of copper working in China, a series of immigrations from the West, and the possibility of copper-working spreading from the West, but a local growth for the Chinese painted pottery.

First, the mass of evidence is against the suggestion that copper-working took its origin in China and it seems more probable that it began in the Near East, although the exact location is unknown at present. Secondly, the evidence of graves makes it unlikely that the spread of painted pottery was due to any large migration (*see CHINA, Racial History*), as such skeletons as have been examined belong to a type which is not very different from the modern Chinese, whereas the users of painted pottery in the Near East belong to an entirely different racial type. In whatever way the use of painted pottery spread, whether by trade or by the introduction of a superior culture by conquest or other method, the people who introduced it were able only to spread the culture but not to alter the physical type of the Far East. Thirdly, a definite distinction must be made between the prehistoric pottery from Kansu and from the rest of China, as hitherto discovered; they can hardly be in the same line of evolution. It seems unlikely that there should be two independent sources of invention of such characteristic pottery and it seems reasonable to suggest that both represent successive waves of migrations of culture from elsewhere. The more eastern pottery has characters of its own in addition to those features which it shares with the Near East. It may, therefore, represent a local development, due possibly to isolation, of a technique originally acquired from outside. Such an hypothesis might serve to explain the absence of metal objects in the sites examined.

Chronology.—The dating assigned to these finds in China necessarily depends to a large extent on the view taken as to its origin. First we have two separate strata, some of the Kansu finds which may well prove, as has been suggested by Andersson, to be later, and the finds from other parts of China which appear to be earlier. If we accept their association with the painted pottery from the Near East the dating in China will depend to a large extent on the chronology accepted for the Near East. Gordon Childe suggests that in Elam and Egypt vases were being painted as early as 5000 B.C., while in Thessaly and in the Ukraine it is unnecessary to go back much beyond 3000 B.C. In Mesopotamia on the whole the consensus of opinion suggests the middle of the 4th millennium B.C. Some authorities suggest a very much earlier date. Gordon Childe on this basis considers that the earliest Chinese finds are really undatable. Arne believes that they belong to the first half of the 3rd millennium B.C., "perhaps very near 3000 B.C." He bases this dating on the assumption that the Chinese finds are more or less synchronous with Susa I. We have, however, no warranty that this assumption is justified. Indeed, the special character of the Chinese pottery suggests that it had time to develop on its own lines. Further he admits that Chinese prehistory has at present an incomplete sequence. The gulf between the Palaeolithic and the Neolithic has not yet been bridged, nor has it been possible to fill in the gap between the true earlier Neolithic and the painted pottery culture. The earliest date of this latter must therefore at present be considered entirely undefined, if we base our chronology on earlier cultures, and on this basis Arne's suggestion of 3000 B.C. is perhaps as probable as any.

Recent evidence, produced by Teilhard, may serve as a *latest* possible date, *i.e.*, the painted pottery may be dated by what came after it, not by what came before. In Honan itself inscriptions written on shell and ivory have been found which appear to belong to the Shang or Yin dynasty. These finds may probably be dated about the middle of the 18th century B.C. (*c.* 1760 B.C.). If this date is correct then in the earlier half of the 2nd millennium B.C. the inhabitants of mid-China not only possessed a system of writing in hieroglyphic characters, but also used ivories and richly decorated bronzes. Neither of these features appears in the painted pottery culture. Therefore the latest possible date for this period is the end of the 3rd millennium B.C. Even this date, however, must be received with a good deal of caution; with our present evidence, however, it seems the most reasonable. Thus the latest finds from Kansu would belong to the end of the 3rd millennium B.C. and the other painted pottery would be earlier; the culture probably existing in China during most of the 3rd millennium B.C. (3000-2000 B.C.), though in view of the marked differ-

ences between the Chinese painted pottery and that from elsewhere it may have had its beginning at an even earlier date. No absolute chronology can be formulated until further evidence has been provided, especially in China and in Sinkiang (Chinese Turkistan).

The evidence so far discussed provides abundant evidence of relations between prehistoric China and the West but throws no light on relations between that country and the Far East. Recent work by the Geological Survey of Indo-China has revealed the existence of a well developed Neolithic culture in that area, which extends to the south, probably over most of south-eastern Asia, but whose northerly extension, as far as it is known at present, appears to lie on the borderland of China. This Indo-Chinese prehistoric culture appears to be entirely separate from any Chinese culture so far known and to constitute an entirely separate archaeological province. That there should have been no form of culture contact is unlikely, but at present it is quite impossible to suggest any definite analogies between this culture and the cultures which have been discussed above. Possibly the geographical conditions and the dense vegetation of tropical south-eastern Asia provided an insuperable barrier, possibly the apparent lack of connection is due entirely to our lack of suitable explored sites.

To the north, however, we have more exact information. Japan has always been closely connected geographically with China and there is every reason to believe that the painted pottery culture of China was not without its influence on Japan. Most of the Japanese Neolithic pottery depends for its ornament either on incised patterns or on relief. It is also characterized at least in one stage by the presence of figurines of quite a different type from anything so far found in China. The development of this early Japanese ware can be traced throughout the Stone Age in Japan and appears to represent a culture which is entirely independent of China, although it shows certain resemblances to some of the early ware from Manchuria and Korea. Painted pottery, however, does occur, although rarely. It seems not unlikely that such specimens represent either imported wares or possibly a local imitation of Chinese ware. It is probable therefore that there was a certain amount of relation between Japan and China in Chalcolithic times. On the other hand fairly extensive excavations have been made in Japan so that it is probable that if the painted ware culture ever existed in Japan it would have been discovered. But there are indications that there was a close connection between Neolithic Japan, at a certain stage and part of the mainland opposite. North-eastern China may, therefore, possibly represent a different cultural province from the rest of northern China, but here again we must wait for further excavations before any definite light can be thrown on the question. There are indications that at least part of this region remained in the Neolithic stage of culture when China itself, or at least the plain of China had developed a high civilization.

Relations Between Chalcolithic Culture and Chinese Civilization.—Andersson, to whom the discovery of this chapter in Chinese prehistory is due, suggests that many features of Chinese civilization are directly descended from the Chalcolithic culture. First, he has suggested that the Li character is directly descended from a pictographic representation of a tripod pot. Arne, however, seems inclined to think that although the development is striking the tripod pot may have been introduced into China once more with true Chinese civilization, from the West. Secondly, the knife at present used by knife-sharpeners in Peking is alleged to be directly descended from a knife found in the Neolithic sites. A type of knife, akin to this form is used to-day to reap Kaoliang (a type of millet). Thirdly, the adze used to-day in Peking appears to be descended from the stone celt by way of the bronze celt. The question of the origin of wheat in China is too controversial and not sufficiently supported by evidence to be included here, but it is at least suggestive that its earliest recorded use is in conjunction with painted pottery in the Near East, so that wheat-growing may be part of the same culture complex of which painted pottery is such a conspicuous element.

We thus have evidence of a Palaeolithic phase, represented by implements and hearths of the middle and upper Palaeolithic

periods. This is followed by a widely spread Neolithic. Presumably at a later date, from analogies elsewhere, there was in China a widely spread culture associated especially with painted pottery, a period which can probably be divided into two parts. But little in this culture can be considered to be definitely Chinese. Certain elements of it seem to have survived in the Chinese culture of the historic period, and as far as we know at present the possessors of this culture did not differ essentially in their physique from the inhabitants of modern north China. Side by side with this culture there seems to have persisted in the north-eastern part of the Chinese dominions a type of Neolithic culture, which probably persisted among barbarous tribes well into the historic period.

DEFENCE

Historical.—Up to the date of the reforms of 1905-06 the Chinese constitution provided for two sorts of military organization, the Manchu army and several armies in the provinces. When the dynasty of 1644 was originally established the victorious troops, mostly composed of Manchus, but including a few of other races, remained in Peking as a hereditary national army. Every adult male was entitled by birth to be enrolled as a soldier under one of the eight banners and, after enrolment, to draw an allowance of tribute rice, whether employed on active service or not. Some were sent to garrison such places as Canton, Foochow, Hangchow, etc., but the bulk of them, both in Peking and elsewhere, lost all military value. The other military organization, the provincial forces, was styled the army of the Green Standard, and resembled a local constabulary rather than an army. They were poorly paid, practically untrained, and badly armed. So matters

THE GREAT WALL OF CHINA

Erected about 225-210 B.C. to keep out the northern barbarians, this wall winds for 1400m. over mountain, valley and river. It consists of a facing of brick, or granite, filled in with earth and, reaching an average height of over 20ft., forms a roadway on the top 13ft. wide. At regular intervals of about a hundred yards it is fortified with a tower

went on, with the soldier and his art held in low repute, until the war with Japan in 1894-95 brought a rude awakening. In Korea, at Port Arthur, and before another fortress, also supposed to be impregnable, at Wei-Hai-Wei, the Chinese troops formed an easy prey for the better led, better organized, and more formidably armed Japanese forces, with their modern equipment and years of training under German expert advice. After the war, some of the corps of "braves" or irregulars were quartered near Peking and

Tientsin and became spoken of generally as the Army of the North. By 1900 this was the only real fighting force which China possessed. After the Boxer rising of 1901 an Imperial decree ordered the reorganization of the military forces of the Empire and something was accomplished on provincial lines, especially in Chihli, but little was done towards establishing an army on European lines until after the Russo-Japanese War of 1904-05, when various military schools and training organizations were established (or provided for on paper). By 1910 some progress had been made towards evolving an efficient body of officers. An army board was organized, and progress made with a general staff. Service, mostly voluntary, was for three years with the colours, three in the reserve, and four in the territorial army. Reservists were called up annually for training, and territorials once in two years. The Japanese system of training was followed. Nine divisions and seven mixed brigades were formed with a total strength of about 60,000 with 350 guns, one-third stationed in Manchuria, the remainder elsewhere. The above-mentioned Green Standard army had been brought under the Minister of War, given a battalion organization, and so on, by an Imperial edict of Sept. 1907, but its duties had remained much as before.

China, although a belligerent on the side of the Allied and Associated Powers, took no effective part in the victory which they achieved over the Central Powers group in the World War of 1914-18. The country was in the throes of internecine strife. In the spring of 1919 the Governments of Great Britain, Spain, Portugal, the United States, Russia, Brazil, France and Japan agreed "effectively to restrain their subjects and citizens from exporting to or importing into China arms and munitions of war and material destined exclusively for their manufacture until the establishment of a Government whose authority is recognized through the whole country." The Governments of the Netherlands, Denmark, Belgium and Italy adhered to the agreement subsequently and the diplomatic body appealed to the Chinese Government to prohibit imports. No effective action has been taken, and the Russian Soviet Government has added its activities to those of the nationals of some of the Signatory Powers in carrying on this traffic, with deplorable results. The import of war material, of which a large surplus remained for disposal in belligerent countries at the time of the Armistice, has been largely supplemented from the resources of the numerous arsenals and factories in Chinese territory, such as those at Mukden, Peiyang, Paotingfu, Tehchow, Tsinanfu, Taiyuanfu, Kaifêngfu, Kunghsien, Sianfu, Hanyang, Nanking, Kiangnan, Changsha, Chêngfu, Foochow, Canton, Swatow, Kiungchow, Yunnanfu and Kalgan.

Present Army.—It can at the present time be said with some truth that no one, even in China, can give a complete and authoritative account of the present-day armies in China. Probably about 2,000,000 Chinese are under arms. An estimate of the military strength (for the moment) of the various forces in the field in Oct. 1927 showed Manchurian forces with Honan allies as numbering 240,000. Chihli-Shantung and Sun Chuan-fang's forces at 150,000; total of the Ankuo-chun group, 390,000; the "National" army (a title which all seem anxious to assume) in various groups, 107,000 under Tang Shêng-chi, 149,000 under Li Tsung-jen, 20,000 under Chang Fa-Kuei, 40,000 under Li Chi-shên; making a total for Kuomintang of 356,500. To these totals must be added 100,000 for Kuominchun and Honan allies, 100,000 Shansi troops, 20,000 (estimated) for Chin Yun-ao and allies, and about 515,000 not at the time taking active part in conflict, including 305,000 Szechwan (nominally Kuomintang) troops.

To write definitely, under such conditions as these about the higher command, the recruitment and service, peace distribution (where there is no peace), military education, and other such matters affecting the Chinese army would be as difficult as it has been to obtain reliable statistics about its exact strength. The higher command, as affecting the Chinese army as a whole, can briefly be described as *nil*. As affecting the organization of armies in the field, it is probable that there are more men serving in "mixed brigades" than there are in "divisions." The term "army corps" is misleading, the term "army" with some descriptive prefix being substituted in China, and such armies being grouped together for

a time under such names as "Thief-Suppression Army," and so forth. A normal mixed brigade may be taken to mean two regiments of infantry, one regiment of cavalry, one battalion of engineers, one or more machine-gun companies, with the necessary transport and auxiliary units. A smaller unit, the "mixed regiment" organized on similar lines for detached service may also be encountered. A division may still, perhaps, be taken as being made up of two infantry brigades, each of two regiments, one cavalry regiment, one artillery regiment, one company of engineers, one of transport, two or more companies of machine-guns, military police, sanitary detachment, field ambulance and band. Say, 748 officers, 10,436 rank and file, and 1,328 followers, but there is no stability in such matters. Some leaders, to avoid raising new units, overfill their ranks. With others, the effectives are far short of the establishments. In theory, Chinese divisions were calculated not long ago as numbering 12,512 of all ranks. Rifles of numerous types of home and foreign make are in the country, and home-made and other machine-guns are popular weapons. Trench mortars are in use and pieces up to 6-in. calibre are said to have been made at Mukden.

Air Forces.—Air forces have been established in various areas on a small scale, machines of various types being in use. The Chinese pilots have been well reported on by foreigners, but the mechanics not so well. Neither are considered satisfactory from the disciplinary point of view. A few aeroplanes are in foreign ownership. 140 aeroplanes in flying condition can be accounted for in the North, about 30 in the South, and a few sea-planes. A fair estimate for the whole number in China has been put at a few more than 1,000.

Foreign Troops.—Though not strictly germane to the subject of Chinese armies, it is important, in connection therewith, to take note of the presence of foreign troops in various parts of China. In the North, Peking and Tientsin, they have the right, by Protocol of 1901, to put the legation quarter in a state of defence, and to occupy selected points between Peking and the sea. Japan keeps troops in the Southern Manchurian railway zone under a treaty of Dec. 1905 with the former Chinese Government. Foreign garrisons in the North, distributed between Peking, Tientsin, Tangku, Tongshan, Chinwangtao and Shanhaikwan, were strongly reinforced in 1927, during the conflict between North and South. The total number at the end of 1927 was 11,880, compared with 4,740 in 1926. The nationalities, in order of numbers, were American, French, British, Japanese and Italian. The Shanghai Defence Force, amounting to a mixed division with armoured cars and attached troops, was in 1927-28 gradually reduced in strength to about a brigade. The Shanghai Volunteer Corps, founded in 1854, is highly efficient. It consists of infantry, machine-gunners, field and light artillery. The total strength is about 1,400, or 1,600 with its reserves. The nationality of the members is British, American, Italian, Japanese, Portuguese and Chinese.

BIBLIOGRAPHY.—See *The China Year Book* for 1928. (G. G. A.)

Navy.—The beginning of a navy in China dates from about the year 1881, approximately the same period as that which saw the introduction of the telegraph into the country. An arsenal at Foochow turned out a few small composite gunboats and a training ship was bought and placed under the command of a British officer. Several armoured cruisers were ordered from England, while naval bases were fortified at Port Arthur and Wei Hai Wei. Forts were also built and guns mounted at Foochow, Shanghai, Canton and other points which appeared vulnerable from the sea. Money for these purposes was forthcoming from the customs duties on foreign trade.

The Chinese fleet had not, however, developed into a formidable force when, in 1884, France had occasion to take reprisals against that nation for attacks by irregular troops in Tonking. A wretched collection of craft, the chief of which was the "Yang-Woo," a composite cruiser, was practically wiped out by a French squadron in seven minutes in the river Min, where it had taken cover, near Foochow.

In 1898, when China found herself at war with Japan, the former country had an appreciable fleet, in fact one which on paper was stronger than her adversary, but owing to the dis-

organized state of administration, only one out of the four squadrons into which it was organized took part in the hostilities. This squadron consisted of two small battleships, the "Chen Yuen" and "Ting Yuen," built in Germany, five other small armoured vessels and six sloops. It had attained a good standard of discipline and efficiency under Captain W. M. Lang of the British Navy, but after his departure and by the time war broke out, the ships had deteriorated and the personnel had relapsed into their normal state of inefficiency. The squadron was defeated by the Japanese fleet at the battle of Yalu.

In 1909 an effort was made to re-establish a fleet and a naval commission under Tsai Hsün, a brother of the Emperor Kwang-sü, was sent to Europe to obtain the necessary information and advice. Various societies had already started in several provinces to collect funds for naval purposes. At this time the fleet consisted of four armoured cruisers, some modern gunboats built in Japan, a few miscellaneous vessels and some old torpedo boats, but the efforts of China to create and maintain a navy have never been crowned with much success, chiefly owing to the corruption of the Government and the irresponsibility of the officers.

In 1928 the Chinese navy was composed of two small armoured cruisers, the "Ying Jui" and "Chao Ho" (two 6 in. and four 4 in.), completed in 1911, four old protected cruisers completed in 1897-98, three old destroyers, a few torpedo boats, a number of river gunboats and auxiliary vessels. Its state of efficiency was decidedly poor, while the internal disruption of the country precluded any prospect of it developing into a force to be regarded seriously in the near future. During the internal struggles of 1926-28, warships changed sides with much impartiality, according to the monetary inducements held out by the various temporary leaders. (E. A.)

HISTORY

Introduction. The Influence of Physical Environment.

Throughout its course the history of China has been profoundly affected by physical environment. In the first place, what is known as China Proper is singularly fitted for a large and civilized population. Fertile valleys, the loess soil, great alluvial plains, a fairly large supply of minerals, a favourable climate and a rainfall which is usually adequate, combine to make the region a natural seat for powerful and highly cultured peoples. In the second place, the mountains and rivers within China Proper offer no insuperable obstacles to the union of the region under one rule. This is especially true of the part of China embracing the Yangtze valley east of the Gorges and the valleys of the Yellow, the Huai and the North rivers. China is fairly easily welded into an empire. On the other hand, these internal barriers, especially those in the west and south-west, are sufficiently marked to stimulate a strong provincial feeling and dialectical differences. Not infrequently—often for centuries—they have permitted political division. In the third place, the great plateaux, deserts and mountains by which China Proper is surrounded have been sources of periodic invasions. The sturdy dwellers in these relatively inhospitable wastes naturally looked with covetous eyes upon the fertile and wealthy plains to the south and east. The necessity of defence against them was constantly with every government of China. Hence the Great Wall. Hence, too, the attempt to control them by the conquest of their homes—Tibet, Sinkiang, Mongolia and Manchuria. Hence, too, the periodic infusion of new blood and the highly mixed character of the present Chinese race. In the fourth place, these land barriers, together with the ocean, until the last hundred years or so prevented many intimate contacts with other seats of culture—India, Persia, Mesopotamia, the Mediterranean and Europe. Some contributions have come from without, notably Buddhism, but on the whole Chinese civilization has been indigenous and until recent times the source of the cultures of all peoples whom the Chinese knew well. This may account in part for the intense pride and conservatism of the Chinese. The breaking of these barriers by the West is responsible for the stupendous revolution of the last few years. In the fifth place, the Chinese have not been a seafaring people. The lack of suitable harbours in the north, the absence of near-by large

nations with whom profitable commerce could be maintained, and especially the great expanse of desirable land in China itself—enough to engross the energies of the Chinese—discouraged maritime enterprise. Not yet have the Chinese occupied all the soil within their natural boundaries, and only within the past 200 years or less have they begun to migrate in numbers across the seas. By their geographic environment, then, the Chinese were encouraged to become a numerous, highly civilized, fairly well unified but mixed race, isolated and self-contained.

Origins.—The origins of the Chinese people and civilization are still undetermined. Many conjectures, some of them very engaging, have been advanced, often with great positiveness. The hypothesis of an Egyptian source no longer finds support. Within the last generation, however, we have had scholars who have maintained that the first Chinese came from the Tigris-Euphrates valley, bringing with them Sumerian culture. Others have held that the Chinese and the earliest civilized inhabitants of Mesopotamia originated in Central Asia, the ancestors of the Chinese moving east in successive waves into the valley of the Hoang Ho, and the Sumerians west and south. Others, basing their arguments chiefly upon the analysis of primitive Chinese written characters, have urged that the first Chinese culture came from the south and south-east. Still, others are inclined to insist that primitive Chinese culture was autochthonous.

The sources of information at present available do not enable us to determine with certainty which, if any, of these conjectures will finally prove to be true. Our oldest Chinese historical literature, that in the *Shu Ching* (*Canon of History*)—parts of it the so-called ("ancient text")—a late forgery, and the earliest extant collection of ancient songs and poems, the *Shih Ching* (*Canon of Odes*), cannot be depended upon for information earlier than the second millennium B.C., and much of that is by no means uncontested. The earliest documents in even these books show a civilization which is already far removed from primitive conditions and contain no certain proof of either a native or a foreign origin of the Chinese. Archaeology has only begun to help us. Researches in Central Asia have disclosed extremely ancient seats of culture east of the Caspian and have suggested the strong probability of migrations from what is now Sinkiang and Mongolia and possibly from farther west, and also the likelihood of very early transmission of some art forms from western Asia and south-eastern Europe. Recently members of the Geological Survey and others have brought to light remains of a neolithic culture in Honan and elsewhere with vessels and implements resembling those in use by the Chinese in historic times. Whether these neolithic peoples were the ancestors of the Chinese and the founders of Chinese culture is at present undetermined. Palaeolithic remains have also been discovered, but their full significance is not yet known. The analysis of early Chinese written characters—even with the aid of the "oracle bones" of Honan, bearing early forms of the characters—is as yet a quite unreliable guide to geographic origins. All that we can say with certainty is that Chinese culture, when we first know it, had its centres in the present Honan and Shensi, that it was already fairly old, and that it and the people who possessed it were probably the result of several strains from different parts of Asia.

Mythical and Legendary Period.—The Chinese, like other peoples, have accounts which attempt to trace their history to its beginnings. Chinese myths speak of gods and demi-gods in what is now Kansu and Shensi, of a first man P'an Ku, who was endowed with supernatural powers and was the first ruler of the world, and of several series of emperors who were followed by Sui Jên, the "Fire Producer," who learned how to kindle fire by watching a bird produce sparks by pecking at a tree.

The Chinese believe that they are on more nearly certain ground when they come to Fu Hsi. They regard him as having introduced matrimony, substituting the patriarchate for the matriarchate, as the inventor of the *pa kua*, or trigrams, much used in divination, as having taught his people hunting, fishing and the care of flocks, as the originator of musical instruments, as having substituted a kind of hieroglyphs for a system of knot-writing previously used, and as having arranged a calendar. Fu Hsi is sup-

posed to have been followed by Shên Nung, to whom is ascribed the introduction of agricultural implements and the tilling of the fields, and the discovery of the medicinal properties of plants. Shên Nung in turn was succeeded by Huang Ti, or the Yellow Emperor, who is held to have extended the boundaries of the Empire, to have regulated the calendar, to have been the first builder of houses and cities, to have organized a board of historiographers and to have improved commerce. His consort is said to have invented the manufacture of silk. Various dates are assigned to these last three rulers, but most chronologies agree in placing them somewhere in the third millennium B.C. Whether these emperors ever existed is uncertain. At best they are but legendary figures.

Huang Ti is supposed to have been followed by four other rulers, and these in turn by the famous rulers, Yao, Shun and Yü. These three are the first monarchs mentioned in the *Shu Ching* and were regarded by Confucius as models. Dates and details are still extremely uncertain, for most of those usually given are of late origin. Even the historicity of the three is to be viewed with some doubt, but they are usually regarded as authentic—even if vague—figures and as belonging to the latter part of the third millennium B.C. Yü is held to have dealt successfully with the problem of draining away the waters of a great flood and to have founded the first dynasty, the Hsia.

Hsia and Shang.—The Hsia dynasty (to which are ascribed the doubtful dates of 2205–1766 B.C.) is said to have come to a close with the reign of an intolerable tyrant, Chieh Kuei, and to have been overthrown by T'ang, who in turn founded another dynasty, the Shang or Yin. The Shang dynasty is said to have lasted from 1766 to 1122 B.C., but again the dates are debatable. Its rulers are reported to have fought, as did the monarchs of so many later dynasties, against the barbarians on the north and west. The Shang dynasty, like its predecessor, is said to have been brought to its end by the misdeeds of its last ruler, Chou Hsin, who was dominated by an infamous concubine, Ta Chi.

The Chou Dynasty.—Condign punishment was inflicted on Chou Hsin by the rulers of the principality of Chou. Chou was on the western frontier, a buffer against the constant pressure of invaders who would seize the fertile plains. It may itself have been founded by a fresh wave of immigrants from the north-west closely related to those controlled by Shang and Hsia. One of the rulers of Chou, Wên Wang, who had, so the records claim, devoted himself to governing well his little state, protested against the cruelties of Chou Hsin and was incarcerated for his pains. While in prison he is said to have produced the *I Ching*, or *Canon of Changes*, a volume based upon the trigrams, and later viewed with great veneration and incorporated into the Confucian Canon. The book is, however, undoubtedly of much later origin. Wên Wang's son, Wu Wang, eventually obtained his father's release and then, after his father's death, with the aid of a coalition of princes, overthrew Chou Hsin and established himself as the first monarch of the Chou dynasty. Wu Wang was greatly aided by his distinguished brother, Chou Kung, or the Duke of Chou, whose regency during the minority of the second emperor of the dynasty is held by orthodox historians to have been ideal. The Chou dynasty was to last until 249 B.C. and so was to have a longer life than any other which has held the throne of China.

The nearly nine centuries of the Chou dynasty witnessed many important developments. First of all, the area of the empire was greatly extended. Expansion carried the Chinese and their culture to the sea on the east, to the Yangtze river on the south, and to the eastern borders of Szechwan. The "barbarians" in these regions appear to have adopted Chinese culture and to have been assimilated by the conquerors. This expansion was for the most part not due to any leadership provided by the imperial house. After the death of its founders, the dynasty produced few monarchs of outstanding ability. One, Mu Wang, is reported to have been a great traveller and to have extended his journeys to the mysterious "Royal Lady of the West" (Hsi Wang Mu). Most of the emperors, however, were distinctly mediocre and some are remembered chiefly for their folly. Yü Wang, for example, to amuse his mistress, had the beacon fires kindled, which were set

to give notice of forays by the barbarians. When at last the barbarians came and the fires were set in earnest, the chieftains, disgruntled, refused to respond and Yü Wang was slain. Such rulers could not lead in foreign conquests. The spread of Chinese power was due chiefly to the energies of adventurers and to heads of subordinate principalities.

In the second place, the empire, as it expanded and as the quality of the Chou declined, tended to break up into semi-independent states. These made war on each other, concluded peace and developed the rudiments of international law, with scant attention to the authority of the imperial house. The power of the central administration more and more fell into abeyance, until, finally, the result was a condition which in many respects resembled European feudalism.

In the third place, the Chou dynasty is memorable for a marked development in culture, and especially in thought. Because of the uncertain dates of many of the older documents, we are not sure in our descriptions of the culture of the Hsia and the Shang dynasties. Bronze vessels attributed to Shang and inscribed with archaic characters have come down to us, a few poems in the *Shih Ching* are assigned to the Shang era, and the *Shu Ching* contains passages which are said to go back before the Hsia. We cannot locate these with enough certainty, however, to dogmatize from them. Before the middle of the Chou dynasty we begin to be on firm ground. Civilization was already well advanced. Agriculture was highly developed with irrigation and the regular division of lands, several of the metals were in use, writing had long been devised by the system of characters which the Chinese still use, literature had come into existence, including poetry, history and state archives, schools were to be found, and industry and commerce had sprung up. Religion was highly developed, with divination, the worship of ancestors and of spirits of hills, rivers, stars and other natural objects, and adoration of a Supreme Being variously called Shang Ti and T'ien. Much emphasis was placed on ceremonies and ritual, both in religion and in official intercourse, and a keen sense of ethical values had developed, reinforced by the belief that the Supreme Being was on the side of righteousness and hated iniquity. Then, as now, the family was the dominant social unit. Our knowledge of the period is not sufficiently complete to enable us to trace all the growth in culture which occurred, nor do we know how much this was due to influences from peoples outside the expanding frontier.

Some developments, however, we do know, chief among them the expansion of thought and the rise of schools of philosophy. Most of the thinkers seem to have been associated with the government. Certainly the problem which chiefly engaged their attention was the welfare of society. Cosmogony did not greatly concern them. To their minds, however, the disorder which attended the breakdown of the central government and the division of the country into warring states dominated by autocratic rulers was of great moment, and they sought to build a new order which would bring happiness to all. More is said elsewhere of the teachings of the Chou philosophers. It is sufficient to state here that Confucius (551-479 B.C.) sought to save society by a return to the way of the ancients. This he believed to involve an emphasis upon ethics—especially upon moral education—and upon ceremonies. By the leadership and example of the educated, and by the careful regulation of society by the ceremonies which had come down from the past he would bring in a golden age. In his train and to greater or less extent approving his solution came others, chief among them Mencius (c. 372-319 B.C.), who stressed the initial

CHINESE GIRLS OF THE WEALTHY CLASS IN RICHLY EMBROIDERED NATIVE COSTUMES

goodness of human nature and the right of subjects to revolt against a persistently unjust ruler. Another school, Taoism, had as its foundation classic the *Tao Tê Ching* and attributed this to one Lao Tzû, who is said to have been an older contemporary of Confucius. The solution for the woes of mankind offered by the *Tao Tê Ching* was conformity to the way of the universe. The way of the universe was believed to be the absence of all man-made restraints and freedom from elaborate regulations and from what passed for civilization. This solution was, obviously, quite different from that advocated by Confucius, and members of the two schools engaged in frequent controversy. Belonging to the school of the *Tao Tê Ching*—Taoism—were many other thinkers, notably Lieh Tzû, probably of the 5th and 4th centuries B.C., and Chuang Tzû, a contemporary of Mencius. In the writings attributed to Lieh Tzû begins to appear a cosmogony, and in Chuang Tzû are accounts of men with miraculous powers. These paved the way for the superstitions of the later Taoists—the use of magic and attempts to achieve immortality by an elixir of life and other pseudo-scientific means. Mo Ti, who lived between the times of Confucius and Mencius and who was the precursor of two schools which for several centuries were to have great vogue but were eventually to disappear, taught that institutions should be submitted to the pragmatic test—were they of benefit to society? He was deeply religious, believed that T'ien (Heaven) loved men, and that all men should love each other. It was his doctrine of universal love as the basis of ethics which brought against him the vigour of Mencius' dialectic. Yang Chu, a contemporary of Mencius, declined to trouble himself about society, maintained that death ended all, and held that each man should live for himself and for his own pleasure. Hsün Tzû, born in 340, denied immortality and the existence of spirits, and held that man, although bad by nature, could be improved by regulations and ceremonies. These and others show how diverse and vigorous was the thought of the age. Never again was Chinese philosophy to be as creative and as little untrammelled by the past. Systems then begun were to persist, dominant, until our own day.

The Ch'in Dynasty.—The philosophers, for all their theories, were unable to prevent the progressive disintegration of the empire. In the 7th century the real leadership went in turn to five states. Hence the name of the period, "The Five Leaders." Under the last Chou emperors internal strife so increased that the final 250 years of the dynasty are dubbed Chan Kuo, "the Contending States." Individualism was the order of the day. In the general anarchy the Chou dynasty at last disappeared. The end of the Chou and the union into one empire of the large territory over which the Chinese people and culture had now spread were achieved by the rulers of the State of Ch'in. Ch'in, on the north-western frontier, had a strong infusion of non-Chinese blood and, like the State of Chou before Wu Wang, had been a buffer against the barbarians. It had grown strong in the process and its princes at last conquered their rivals and took the emblems of imperial power from the weaklings of the Chou line. The last of the Chous was deposed in 249 B.C. The welding of the vast new domains of the Ch'in into a unified State was the work of one of the greatest political geniuses of Chinese history, the Ch'in ruler who ascended the throne in 246 B.C., and who styled himself Shih Huang Ti, the "First Emperor." Ch'in Shih Huang Ti abolished the political system of the Chou with its many petty states and hereditary princes, and divided the country into 36 provinces, over each of which he set officials appointed by and directly responsible to himself. As an emblem and centre of his power he built a capital on the site of the present Hsianfu. He introduced a uniform system of laws, weights and measures, thus aiding both unity and commerce. He greatly extended the boundaries of the empire, carrying his arms into what is now Fukien, Kwangtung and Kwangsi, and against the barbarians—the Hsiung Nu—on the northern and western frontiers. To defend his borders on the side from which they were most frequently attacked, he constructed the Great Wall. This had probably already existed in part, but he completed and strengthened it. Later orthodox scholars held his name in reproach for one of the signal acts of his reign, the

"Burning of the Books." What motives lay behind this deed we do not certainly know: he may have believed that the scholars who were forever harping on the past and the literature which made sacred the institutions of the old régime were an enemy to the new order which he was trying to establish. Whatever his motives, he had the existing literature collected and burned, exempting only books dealing with divination, pharmacy, medicine, agriculture and arboriculture. He commanded scholars to desist from discussing the past. The old order did not expire without a struggle. Ch'in Shih Huang Ti died in 210 B.C. and almost as soon as his strong hand was removed the structure he had erected collapsed. Insurrection broke out, the feeble "Second Emperor" was murdered (207 B.C.), and military chieftains set to fighting for the throne.

The Han Dynasty.—Out of the renewed civil strife one of the contestants, Liu Pang, shortly emerged victorious and founded the Han dynasty (202 B.C.—Liu Pang counted his reign as having begun in 206 B.C.). The effort of Ch'in Shih Huang Ti had not been in vain. The "feudalism" of the last years of the Chou had been so badly shattered that Liu Pang found it possible quickly to unite the country. At the beginning the Han attempted to rule the empire by a system which was a combination of that instituted by the Ch'in and of "feudalism." Members of the emperor's family were placed over the main divisions of the realm. This compromise carried with it the seeds of the old pernicious particularism, however, and after about a century the principle of hereditary local power was curtailed, and the practice was adopted of governing through a civil service recruited on the basis of worth. Worth was to be discovered in part by means of examinations and these were based on the classics of the Confucian school. This practice of recruiting officials by means of examinations probably had its roots in the Chou dynasty, but it was now developed and was for the first time employed as a means of governing the entire empire. It was to be greatly enlarged by later dynasties and was to be a means of holding the country together. It was one of the most successful political devices ever invented by man.

With the consolidation of China went foreign conquests. The major ones date from the long and brilliant reign of Wu Ti (140–86 B.C.). The Han arms were directed chiefly against the barbarians on the north-west, especially the Hsiung Nu. Alliances against this common foe were made with other Central Asiatic peoples. Generals and ambassadors were despatched to effect the conquest, notably Chang Ch'ien, who went as far west as Bactria. The power of the Hsiung Nu was broken and the Han rule was extended into what is now Sinkiang. In the dry air of the far north-west fortresses and walls built by the Han to guard the frontier have survived to our own day. The Han also carried their arms south of the Yangtze as far as Tongking, and to the north-east into Korea.

With unity, increased prosperity and conquests came foreign trade. The caravan routes to the West had been made safe by the defeat of the Hsiung Nu, and products from Central Asia and even from the outposts of the Hellenistic world reached China, and Chinese goods were sent in exchange.

Literature and art revived. The first emperor of the Han declined to remove the prohibition of Ch'in Shih Huang Ti against the ancient books. The ban was lifted by his successor, however; documents which had escaped the holocaust were brought out from their hiding places, and scholars devoted themselves to restoring the texts and writing commentaries on them. The Han cannot boast of as much original philosophical thought as can the Chou: it may be that the emphasis placed by the State upon the study of the classics of the Confucian school discouraged heterodoxy. Taoism was espoused by many in high position, but it degenerated more and more into magic and the search for the elixir of life and for means of transmuting the baser metals into gold. Historiography was greatly developed, however, the outstanding work being the monumental *Historical Records* (*Shih Chi*) of Ssu-ma Ch'ien. Poetry, too, revived. In art the Han period showed many new forms, some of them influenced profoundly by contacts with Central Asia and the West.

The Han rule suffered a temporary interruption when, in the 1st

century of the Christian era, a usurper, Wang Mang, poisoned one emperor, set aside an infant successor (A.D. 9), and for a few years ruled as the "New Emperor." Princes of the Han, however, defeated and killed him, and in A.D. 25 restored the dynasty. The capital was now moved from Ch'ang-an in the present Shensi to Lo-yang in the present Honan. The dynasty after this interruption is known as the Later or—because of the change of capital—Eastern Han as distinguished from the Earlier or Western Han. The Later Han renewed the conquests in the West and under Gen. Pan Ch'ao the Chinese became masters of parts of Central Asia and received tribute even from peoples on the Oxus. A Chinese embassy reached the Persian Gulf. Because of the control by the Han of the caravan routes to Central Asia, and partly because of the possession of Tongking and the south, commerce was maintained with the Roman Orient—known to the Chinese as Ta Ts'in—both by land and by sea. Chinese silks and iron were carried to the Mediterranean world, and products from Central Asia and the Hellenistic world were brought to China.

Through these contacts with the West came Buddhism. The story, which attributes its introduction to a dream of the Emperor Ming Ti, is a pious fabrication of a later age, but that it entered China under the Han is certain. The Later Han continued the patronage to letters, and especially to the Confucian school, which had been accorded by the Earlier Han. Literature flourished and was furthered by the invention of paper (c. A.D. 150).

The annals of the Han dynasty, like those both of its predecessors and successors, are punctuated by rebellions and intrigues. As the imperial line became weak, these succeeded in bringing it to an end, and a period of disunion followed which was to last for nearly four centuries. So thoroughly had the Han emperors welded China together, however, that cultural unity and the vision of a single empire were never lost, and to this day the Chinese call themselves the "Sons of Han." Under the Ch'in and the Han China had for the first time become a great State.

Three-and-a-Half Centuries of Disunion (the "Three Kingdoms").—The Later Han technically came to an end in the year 220. It was succeeded by three states—the "Three Kingdoms"—Wei in the north, ruled by the successors of Ts'ao Ts'ao, minister and betrayer of the last of the Han, Wu in the central and lower part of the Yangtze valley, with its capital at Nanking, and Shu, in Szechwan, whose monarchs, of the house of Han, claimed title to the entire empire and, for its Han connection, known as the Minor or Shu Han. The period was one of almost constant war and is famed for the exploits of its chief figures, popularized for later ages by the stage and the great historical novel, *San Kuo*. Liu Pei, the first prince of the Minor Han, was aided by Chang Fei and Kuan Yü, the latter of whom was later deified as the God of War, Kuan Ti. He was also assisted by Chu-ko Liang, who was noted as a strategist and as the inventor of war machines. The fortunes of war varied, but not one of the three kingdoms was able long to conquer the other two. For a brief time the Minor Han was in the ascendant, but the folly of its second ruler soon brought it to an end and its territories were annexed by Wei. Wei fell under the control of the Ssu-ma family and in A.D. 265 Ssu-ma Yen deposed his sovereign and proclaimed a new dynasty, the Western Chin (A.D. 265–317). For a brief time nearly all of China was under the rule of this house, but the union was short-lived.

To domestic dissension was being added foreign invasion. Peoples from the north and west—Tatars, Hsiung Nu and Tibetans—took advantage of the internal weakness of the fertile lands to the east and south, and seized much of the territory north of the Yangtze. Many ephemeral states and dynasties followed, the invaders striving to establish themselves in the north, and the Chinese, from the south, endeavouring to beat them back. The period is accordingly known as the epoch of the northern and southern dynasties. The most prominent among many dynasties of the period were the Eastern Chin (A.D. 317–420), with its capital at Nanking, the Sung (A.D. 420–479, called Liu Sung to distinguish it from the later and more famous Sung dynasty), also with its capital at Nanking, the Northern or Yüan Wei (A.D. 386–636), of the Toba Tatars, with its capital at the present Ta-t'ung in Shansi,

and at its end dividing into the western and the eastern Wei, the Ch'i (A.D. 479-502), the Liang (A.D. 502-557) and the Ch'en (A.D. 557-589).

The period was one of transition in civilization. The invaders adopted Chinese culture, but they could not but modify it. Buddhism now achieved popularity, perhaps in part because with the breakdown of central authority the Confucian school could not offer the resistance that it could under the Han. Many of the monarchs espoused the foreign cult, missionaries came in numbers, and Chinese, the best known of whom was Fa Hsien, went on pilgrimages to the sacred sites in India and returned with Buddhist scriptures. By the time that the empire was once more united, Buddhism had become an integral part of its life and was having profound effects upon other religions, popular thought, literature and art. The Buddhist sculptures of the period are noteworthy. During the last years of disunion and during the first century or two of the union which followed, Buddhism was more prosperous than it was ever again to be in China. The many new sects which arose within it testified to its vigour.

The Sui and the T'ang.—After a long period of division, union was once more achieved, first under the Sui dynasty (A.D. 589-618) and then under the T'ang (A.D. 618-907). Under the second emperor of the T'ang, T'ai Tsung (A.D. 627-650), China became more powerful than she had been since the Han and was for a time the strongest and largest empire on earth. Under the T'ang Chinese arms were carried again into Korea, into Turkistan, across the Pamirs to north-west India and into Tibet. To China, and especially to the T'ang court at Ch'ang-an, the present Hsianfu, journeyed peoples of many lands and faiths. Muslims, Nestorians, and followers of Manichaeism came, and Persians sought aid against the Muslim Arab wave of invasion. The Nestorians had numerous missionaries and churches in China, and, apparently, a fairly extensive literature. Japanese carried home ideas which were to continue the revolution in the life of their nation that contact with China immediately before the T'ang had begun. Chinese Buddhist pilgrims, too, continued to visit India.

Under the T'ang the bureaucracy and its accompanying civil service examinations were further developed and the latter were capped by the foundation of the Han Lin academy, charged with the compilation of histories, the drafting of decrees and other literary labours.

Under the T'ang prosperity, brought by the arts of peace, flourished. Painting reached new heights and China's most famous poets wrote. Among the latter the most distinguished was the Bohemian and attractive Li T'ai-po. From the T'ang dynasty dates the earliest known printed book, and paper money then first made its appearance.

Of the many rulers of the T'ang little need be said here. Besides T'ai Tsung the best remembered was probably the able and unscrupulous empress Wu Hou, who in the 7th century dominated the throne and for a time assumed imperial powers under a new dynastic name. In the 9th century the quality of the emperors declined, the palace eunuchs attained undue power, invasions and rebellions decimated the population, and in A.D. 907 the dynasty was brought to an end.

The Five Dynasties (A.D. 907-960).—Following the T'ang various aspirants for imperial honours fought for the throne, and in quick succession there followed five ephemeral dynasties, known as the Later Liang, the Later T'ang, the Later Chin, the Later Han and the Later Chou. Their assumption of famous names did not prevent the early demise of each, and in 960 the last gave way to the Sung dynasty.

The Sung Dynasty (A.D. 960-1280).—The Sung dynasty, founded by Chao Kuang-yin, began auspiciously. Most of the country was reduced to submission, the capital was placed at Kai-feng, near the site of the glories of past dynasties, and a further step toward centralizing power in the hands of the emperor was taken in creating a national board of punishments, to which, rather than to the provincial authorities, as formerly, the final decree in capital offences was entrusted. Before long evil days came. An attempt to conquer the K'itans, a Tungusic people who ruled the Liaotung peninsula, proved unsuccessful, and the K'itans occupied

portions of the empire adjoining their domains and were prevented from further depredations only by the payment of tribute. On the north-west another kingdom, that of Hsia, threatened the frontiers and fought both the Sung and the K'itans. The Sung called to their assistance the Chin ("Golden") Tatars, but these, after expelling the K'itans, made themselves masters of the territory north of the Yangtze and the Sung were constrained to move their capital first to Nanking and then to Hangchow. In the wake of the Chin came the Mongols. The great Mongol general, Temuchin, or Jenghiz Khan, invaded China early in the 13th century. By 1214 he had possession of most of the country north of the Yellow river, having defeated the Chin. Before his death (1227) Jenghiz had made further inroads on the Chin and had defeated the Hsia. Jenghiz' successor, Ogodai, formed an alliance with the Sung and the two made an end of the Chin. The allies then fell out and the Mongols under Ogodai, Mangu and Khublai pressed south, until, after the last of the Sung monarchs had in despair cast himself into the sea, Khublai in 1280 became emperor of all China.

The military misfortunes of the Sung did not prevent the dynasty from synchronizing with one of the great creative periods of Chinese culture. Painting, under the influence of Buddhism and Taoism, reached its highest point. Philosophical schools contended with each other, and one, culminating in Chu Hsi (A.D. 1130-1200), gave Confucianism the form which until the 20th century was to be regarded as orthodox. Notable histories were written, among them that of Ssu-ma Kuang. An interesting experiment in economic and political reorganization was made under the leadership of Wang An-shih (A.D. 1021-86). Wang An-shih was a brilliant and thorough-going radical. He sought to change the existing educational system and make it of more practical use. He issued original commentaries on the classics, reading new meanings into these ancient documents. For 18 years, as prime minister, he inaugurated and superintended what resembled the European state socialism of the 19th century. His object was to make the State responsible for ensuring to the masses the opportunity for obtaining the necessities of life. To this end he would have the government take over the entire management of commerce, industry and agriculture, regulate wages and prices, distribute seed, make loans to the farmers at moderate rates of interest, and place the burden of taxation on the rich. He also put upon every family the burden of military defence. Wang inevitably had many enemies and critics, one of the chief being Ssu-ma Kuang. These eventually forced his retirement and restored the *status quo*.

The Mongol Dynasty (A.D. 1280-1368).—The Mongol or, as it was officially known, the Yüan dynasty, was not of long duration. The reign of Khublai was brilliant. From his capital at Khanbaliqu, or Cambaluc, on approximately the site of the present Peking, he ruled not only over China but over most of the vast Mongol empire, with its western frontiers in Mesopotamia and Europe. Expeditions were sent into Cambodia, Burma and Java, and against Japan. Under him, however, Mongol power reached its climax. The invasion of Cambodia ended in a somewhat inglorious retirement, the attempt on Java was unsuccessful and the armada against Japan met with overwhelming disaster. The Mongols ruled China largely as conquerors and brought in many foreign troops and hordes of foreign officials. After Khublai the ability of the monarchs rapidly declined, rebellions arose, the Mongols were expelled and in 1368 the most successful of their opponents, an ex-Buddhist monk, Chu Yüan-chang, became the first emperor of a new dynasty, the Ming.

The Yüan dynasty, brief though it was, was not without notable developments. The Grand Canal was completed, and drama and the novel first became important. The safety of the trans-Asiatic trade routes under Mongol rule and the Mongol method of government brought many foreigners into China. Nestorian Christianity had survived on the edges of the empire since the T'ang and now reappeared in China, Muslims entered in fairly large numbers, and even Armenians were to be found. Now for the first time western Europeans made their way to China. The eastward expansion of Europe in the Crusades and Italian commerce, and the burst of missionary enthusiasm through the Franciscan and Dominican orders brought Europeans to the western fringes of the

Mongol empire. It was natural that European merchants and missionaries should make their way to China—or Cathay, as they called it. Most notable among the merchants were the Venetians, Nicolo and Maffeo Polo, and the son of Nicolo, Marco. Marco Polo was for years in the service of Khublai and, returning to Venice, wrote the account of his travels which has made him famous. Friars were sent as envoys to the Mongol rulers in Central Asia, but so far as we know the first to reach China was the Franciscan, John of Montecorvino, who arrived at Khanbaliq in 1294 and there, in the ensuing three decades or more, built up a Christian community numbering several thousands. When the news of his success reached Europe he was created archbishop of Khanbaliq, and reinforcements were sent him. In the course of the next few years numbers of other missionaries arrived, notably a papal legate, John of Marignolli. With the collapse of Mongol rule, however, the trade routes became unsafe, an anti-foreign reaction set in and Europeans, both merchants and missionaries, disappeared from China and the Catholic Nestorian communities passed out of existence.

The Ming Dynasty (1368–1644).—The new and purely Chinese dynasty, the Ming, was not, as its name had promised, noteworthy for its brilliance. Under it, however, the empire was fairly prosperous. The first emperor, Chu Yüan-chang, better known by his reign title, Hung Wu, unified the country and established his capitals at Nanking and K'ai-feng. His fourth son, the third emperor, commonly known by his reign title, Yung Lo, came to the throne through a sea of blood, but proved an able ruler. He was a great builder: he moved his seat to Peking, and the palaces and temples which to this day make the city architecturally one of the outstanding capitals of the world were largely his work. He was a patron of literature. He sent expeditions to the south and south-east as far as Java and Ceylon. One of the princes of Ceylon was brought captive to China and for years tribute came from the island. Under a succeeding monarch an expedition was sent by sea as far as the Persian gulf. Under the Ming emperors, moreover, Korea was invaded, Annam for a time became subject to China and frequent wars with the Mongols usually kept those ancient enemies at bay. As time passed the decline which was the inevitable fate of dynasties brought weakness to the empire. The Japanese successfully invaded Korea and for decades Japanese pirates ravaged the coasts.

In cultural achievements the Ming period is not remembered for any marked creativeness. Philosophy was dominated by Chu Hsi, and one thinker, Wang Yang-ming (1472–1528), challenged the orthodox school with sufficient originality and success to be prominently remembered. In literature most of the energy of scholars was expended in compiling encyclopaedias and in collecting and editing the works of the past. Architecture there was, and ceramics and lacquer of great beauty, but painting did not reach the heights that it had under the Sung. China was populous and wealthy but did not show the ability of some preceding dynasties.

The Ming period was made memorable by the renewed coming of Europeans. The European voyages and conquests of the 16th century brought the Portuguese to India, Malacca, China and Japan, and the Spaniards to the Philippines. The first Portuguese reached China about 1514 and before many years had established themselves at several ports. The first comers were so truculent, however, that before long they were driven out or massacred. For a brief time the Portuguese traded from the island of Shang-chuan, south of Canton, but shortly were permitted to form a settlement at Macao—the exact date is uncertain, but was probably between 1552 and 1560—and retained that as their base. Missionaries came. St. Francis Xavier died on Shang-chuan in 1552 while engaged in a vain attempt to enter the empire. His fellow Jesuits renewed the effort and before the close of the century had established themselves in several cities in the interior. The ablest of their number was Matthew Ricci (1552–1610), an Italian, who arrived in China in 1582 and in 1601 succeeded in effecting a residence in Peking. Ricci and his associates commended themselves to the scholar-official class by their knowledge of science, especially of mathematics and astronomy, and

were placed in charge of the government's bureau of astronomy in Peking.

The Manchus.—The weakening Ming dynasty was overthrown by invaders from the north-east, the Manchus. The Manchus had been welded into a formidable army by Nurhachu (1559–1627) and before his death had aspired to the empire. Their opportunity came when, in 1644, a rebel, Li Tzu-ch'eng, made himself master of Peking and the Ming emperor committed suicide. A Ming general, Wu San-kuei, joined forces with the Manchus to oust Li, and a Manchu prince was placed on the throne. Ming claimants did not tamely submit, and it was not until 1662 that the last of them, driven, after stubborn resistance, to the Burmese borders of Yünnan, acknowledged defeat by taking his own life. Somewhat later, the successors of Koxinga, who had been implacable toward the Manchus and had harried the south coast and had ruled Formosa, were eliminated.

For a century and a half the Manchus filled the throne with able rulers. The monarchs, whose reigns were named K'ang Hsi (1662–1723) and, after the brief interlude of Yung Ch'eng (1723–36), Ch'ien Lung (1736–96), had, from the standpoint of foreign conquests and domestic prosperity, as brilliant careers as the empire had known. The Manchus ruled as conquerors and maintained permanent garrisons in strategic centres throughout the country, but they adopted Chinese culture, perpetuated the time-honoured administrative machinery and laws, associated Chinese with themselves in the highest boards at Peking, and opened to them all the provincial offices. They guarded against revolt by forbidding a Chinese to hold office in his native province, by frequently shifting officials, and by dividing the administrative responsibility for each province among several officers who could serve as a check on each other. They vigorously put down revolts, notably that of Wu San-kuei, to whose aid they largely owed the throne. They ruled Manchuria, they conquered Mongolia; under K'ang Hsi they added Tibet to their possessions and, under Ch'ien Lung, Ili and Turkistan. Ch'ien Lung's armies penetrated Burma and Cochinchina and Korea paid tribute. Never had the empire covered so much territory, and never had it been as populous. With the reign of Ch'ien Lung the dynasty passed its zenith, and after it the quality of the ruling house declined. In the later years of Ch'ien Lung and under Chia Ch'ing (1796–1821), Tao Kuang (1821–51), Hsien Feng (1851–62) and T'ung Chih (1862–75) numerous rebellions kept part or all of the country in turmoil.

The outstanding series of events of the Manchu dynasty was connected with the increasing pressure of European peoples upon China. Catholic missionaries continued to come. To the Jesuits were added in the 17th century Franciscans, Dominicans and Augustinians from the Philippines, Franciscans from Italy, and members of the Société des Missions Étrangères of Paris. With the exception of a brief interval during the minority of K'ang Hsi, Jesuits remained in charge of the Bureau of Astronomy and under K'ang Hsi and Ch'ien Lung were assigned further scientific tasks, among them the mapping of the empire. The names most prominent in the Peking mission were Schall and his successor, Verbiest, but the group contained many other able men. In 1692 K'ang Hsi issued what amounted to an edict of toleration, and for a number of years the Church prospered greatly. Missionaries and Christian communities were to be found in all the provinces, and by 1700 the Catholics in the empire probably numbered about 300,000. Then came a series of reverses. A prolonged controversy over the question of what Chinese term should be used for God and of what attitude should be taken by Christians toward certain Chinese rites, among them the honours paid to ancestors and to Confucius, divided the foreign staff. When Rome finally spoke, the decision antagonized K'ang Hsi and the Chinese scholar class. Repeated persecutions arose—only in part because of the decision on the rites; in 1773 papal orders dissolved the Society of Jesus, and the Lazarists, in spite of valiant attempts, could not fully take its place. Religious indifference in Europe, due to the Enlightenment, and the French Revolution and the wars of Napoleon, cut off support from home. By 1800 the Catholics in the empire numbered only about 200,000 and were badly demoralized. Between 1600 and 1800, however, Catholic missionaries had

helped to acquaint China with European science and religion and, by their writings, had spread in Europe a knowledge of China.

European merchants did not penetrate the empire as did the missionaries, but they continued to come. Although their commerce declined, the Portuguese retained Macao. The French, Dutch and British opened trade with China, and in 1784 came the first ship from the United States, the precursor of many more. By the middle of the 18th century British trade was more important than that of any other Occidental people and was the official monopoly of the English East India Company. Chinese teas, silks and cottons were in great demand in Europe, and for a time were paid for largely by specie. Eventually, however, the importation of opium, chiefly from India and on British ships, brought a reversal of the balance of trade.

Commerce was carried on under great restrictions. By the close of the 18th century only one port, Canton, was open to merchants from abroad. The Europeans were there confined to a small area—the “factories”—and were ordered to spend the quiet months in Macao. Business could be conducted only through an officially designated group of Chinese merchants, the co-hong. The absence of fixed tariff charges, the exactions of venal officials, the unwillingness of the Chinese to permit official intercourse on the basis of equality, the prohibition against a Chinese teaching a foreigner the language, the subjection of the foreigner to Chinese laws and courts, were all galling to the Westerner. Russia had little if any better treatment. K'ang Hsi had momentarily checked the Russian advance by the capture of Albazin (1685) and there followed the first treaty to be signed with a European Power, that of Nerchinsk (1689), which, with its successor, the treaty of Kiakhta (1727), provided for trade, diplomatic intercourse—in part through a resident Russian mission in Peking—and the extradition of criminals.

Repeated attempts were made to obtain better terms. Portuguese, Dutch and British embassies travelled to Peking, notably those of the British in 1793 and 1816, led respectively by Macartney and Amherst, but to no avail. The Chinese had never been accustomed to dealing with other governments on the basis of equality and regarded all foreign envoys as bearers of tribute.

The First War with Great Britain and the First Group of Foreign Treaties (1839-44).—Such a condition of affairs could not endure. The industrial revolution inaugurated a period of renewed expansion of the Occident, and the West desired admission to China to market the products of its factories and to obtain raw materials. Pressure first came from Great Britain, the European nation in which the industrial revolution began. On demand from British merchants the monopoly of the China trade by the English East India Company was abolished (1834) and friction between the English and the Chinese followed. Lord Napier was appointed the first “superintendent” of British trade in Canton (1834), but Chinese officials looked upon him as a head merchant and refused to deal with him as an equal. Lord Napier died under the strain of his anomalous position and his successors were unable to effect any improvement in the situation. Armed conflict was all but inevitable. British merchants were insisting upon more privileges than the Chinese were willing to concede, and British and Chinese ideas of international intercourse were fundamentally at variance—the one government being accustomed to a family of equal nations, the other knowing only an empire and subject peoples. Conceptions of law differed: the Chinese, with their emphasis on group responsibility, holding the entire British community liable for the misdemeanour of any of its members and insisting upon a life for a life, even when death had been accidental, and the British contending that upon the individual and not the community should be placed the responsibility for misdeeds. The conflict came to a head over the question of the importation of opium. This had long been prohibited by the Chinese government, but foreign merchants brought it in ever-increasing quantities and corrupt Chinese officials connived at its introduction. After many futile attempts at enforcement, Peking at last took vigorous action and despatched a special commissioner, Lin Tsê-hsü, to stamp out the trade. Lin arrived at Canton in 1839 and promptly set about his task.

Foreign merchants were compelled to surrender their stocks of opium for destruction, and pressure was put upon them to give bond not to engage further in the importation of the drug. The British objected to what seemed to them high-handed measures, and in November, 1839, hostilities broke out. The Chinese were repeatedly defeated. The war dragged out until 1842, however, for the British contented themselves largely with attacks on centres south of the Yangtze, and their victories alternated with unsuccessful attempts at negotiation. Finally, when Chinkiang—at the intersection of the Yangtze and the Grand Canal—was taken and Peking's communications with the south were threatened, the imperial authorities were frightened into concessions, and on Aug. 29, 1842, the Treaty of Nanking was signed.

This document provided for the cession of the island of Hong-kong to Great Britain, for the opening to foreign residence and commerce of five ports, Canton, Amoy, Foochow, Ningpo and Shanghai, for liberty to appoint consuls at each port, for communication between British and Chinese officials of the same rank on the basis of equality, for an indemnity to the British, for the abolition of the co-hong, and for a “fair and regular tariff.” In 1843 regulations for trade were agreed upon and published, and a supplementary treaty was signed which fixed the tariff rates, assured to the British “most favoured nation” treatment, and contained the rudiments of extraterritoriality. Other western nations took advantage of China's defeat. The Americans sent a commissioner, Caleb Cushing, who negotiated a treaty which conceded, in general, the same commercial privileges to Americans which had been granted to the British, and which, among other things, removed American citizens engaged in the opium traffic from the protection of their government, elaborated extraterritoriality, and provided for the revision of the treaty at the end of 12 years. In 1844 the French obtained a treaty which had much the same provisions for trade and official intercourse as were guaranteed by the British and American documents. At the instance of the French, imperial edicts were issued providing for the toleration of catholic Christianity and for the restoration of the Church property which had been sequestered in the persecutions of the previous century. In the next few years the Belgians and the Swedes were also given treaties.

The Second Foreign War and the Second Group of Treaties, 1856-60.—The years between 1842 and 1856 were in effect a troubled truce. The treaties of 1842 and 1844 were satisfactory neither to foreigners nor to Chinese. From the standpoint of the foreigner they did not grant enough. No provision was made for travel in the interior, for residence in other places than the five open ports, or for direct diplomatic intercourse through representatives resident in Peking. The Chinese, on the other hand, believed that the treaties conceded too much, and since they had been extracted by force, the authorities were not disposed to abide by them any more than they were compelled to do. The Chinese were no further inclined than formerly to treat Western “barbarians” as equals. Clashes were frequent. Moreover, the British treaties said nothing about opium, and the traffic in the drug continued, a constant source of friction. While the Americans, the British and the French were demanding that revision of the treaties which had been promised in the documents of 1844, war between the British and the Chinese broke out—as is often the case in times of international tension—over a comparatively minor incident, the violation by the Chinese of a British flag and the arrest of the crew, all Chinese, on a Chinese-owned but British-registered craft, the lorcha “Arrow” (Oct. 8, 1856). The French, then closely associated with the British through the Crimean War, found in the judicial murder of a Roman Catholic missionary, Chapdelaine, in Kwangsi (Feb. 29, 1856), an occasion for joining in the conflict. The two Powers did not at first press the war, for they were just emerging from the struggle in the Crimea and difficulties with Persia in 1856-57, and the Sepoy mutiny, which blazed out in India in 1857, engrossed the attention of the British. Late in 1857, however, the British and French took Canton, and in the following year their squadrons went north to Tientsin, thence to threaten Peking into submission. The Taku forts, commanding the entrance to Tien-

tsin, were captured, and to save the capital the Chinese granted the desired treaties. The Russian and American representatives, although their governments had not joined in the war, were on hand to profit by the French and British successes and also obtained treaties.

The treaties of Tientsin (1858) in general contained the following provisions: (1) the tariff was modified, and by the fixing of a rate for opium the importation of that drug was legalized; (2) the residence in Peking of diplomatic representatives of the powers was promised; (3) foreigners were to be permitted to travel in the interior; (4) the activities of Christian missionaries were sanctioned, and Christians, both foreign and Chinese, were guaranteed freedom in the practice of their faith; (5) foreign merchant vessels were allowed on the Yangtze; (6) several additional ports were opened to foreign residence and trade, including Chefoo and Newchwang in the north, one on Hainan, two on Formosa, and four on the Yangtze; (7) extraterritoriality was further elaborated; (8) regulations for trade, including the collection of customs, were developed; and (9) indemnities were promised.

When, in 1859, the envoys came to exchange the ratifications of the treaties and to take up their residence in Peking, they found the road by Tientsin blocked and the Chinese prepared to conduct them to the capital by the port which was used by the bearers of tribute from subject states. The Chinese, moreover, proposed the reconsideration of the treaties. The American minister chose to go to the capital by the suggested route and returned after the ceremony. The Russians were received by still another route. Neither gained much in dignity. The British and French, however, attempted to force their way past the Taku forts and were repulsed. The two Powers accordingly renewed the war and in 1860 fought their way through Tientsin to Peking. Peking was captured, the emperor fled to Jehol, and the British, in retaliation for the violation of a flag of truce and the imprisonment of its bearers, set fire to such of the summer palace as had escaped marauding Chinese troops. The Chinese were now constrained to sign conventions by which they agreed to observe the treaties of 1858, to pay an additional indemnity, to open Tientsin to trade, and to permit—more definitely than agreed upon in 1858—the permanent residence of foreign ministers in Peking. The British were ceded the Kowloon promontory opposite Hongkong, and through the French was obtained treaty sanction for what had been promised earlier, the restoration of confiscated catholic church property. In the Chinese, although not in the official (French), text of the French convention was also permission for French missionaries to lease or buy land and build houses in the interior. The Russians, still fishing in troubled waters, obtained a modification of their frontier by which the territory south of the Amur and east of the Ussuri was awarded them—a long stretch of coast which included the site of Vladivostok.

The treaties of 1842-44 and 1858-60 defined the legal basis on which intercourse between the Occident and China was to be conducted. They have since been modified in details, but in their main outlines they are still the basis of the legal status of foreigners in China. While at the time they seemed to solve a troublesome situation, they weakened Chinese sovereignty and threatened the existence of the State—partly by removing foreigners from Chinese jurisdiction, partly by their regulation of the tariff, and partly by making Christian communities *imperio in imperio*.

The T'ai P'ing Rebellion and Other Revolts and the Revival of the Manchu Power.—While the Powers by their blows from without were lowering the prestige of the Manchus and were weakening the Imperial structure, a rebellion which had its roots partly in foreign contacts was threatening the Manchu rule from within. This rebellion had its origin in a Hakka, Hung Hsiu-ch'üan. Hung, a school teacher and an unsuccessful competitor in the civil service examinations, in his young manhood suffered a serious illness which was accompanied by bizarre visions. These visions he later interpreted in the light of some books prepared by Protestants and which had been

given him years before while he was in Canton. He believed that he was called by God to wean the Chinese from the worship of idols. To this end he preached (in the '40s) in Kwangtung and Kwangsi. His followers formed themselves into societies, seemingly chiefly at the instance of a companion, Feng Yün-shan, and about 1848 were welded into fighting units and a political force with aspirations to the throne, probably by an adventurer, Chu Chiu-t'ao. In 1851 they seized a city of some importance in Kwangsi but there lost Chu—captured and executed by the Manchus. In spite of this loss, the insurgents moved north into Hunan and from there down the Yangtze, until in 1853 they took Nanking. Their serious expedition to the north failed, but at Nanking they ruled for over a decade, a fanatical sect whose faith was an ill-assorted blend of misunderstood Christianity and native Chinese beliefs. They showed an utter lack of ability to organize their conquests and owed their temporary success more to the weakness of the imperial government than to their own prowess. They were eventually (1864) put down, chiefly by Tsêng Kuo-fan, but with the aid of a picturesque foreign-officered force which was headed first by an American, Ward, and later by an English major, Charles George Gordon. The rebellion had cost millions of lives and had wasted some of China's fairest provinces.

During the T'ai P'ing rebellion the imperial government, in desperate straits for revenue, resorted to *likin* (internal transit taxes on commerce) and, the crisis once past, continued it. During the rebellion, too, as a convenience for the imperial authorities, the system began of collecting the maritime customs through the agency of foreigners. This expedient was first adopted in Shanghai, but proved so acceptable to both Chinese and foreigners that it was extended to other ports. The Imperial Maritime Customs service so developed was in 1863 placed under the direction of Robert Hart, and through his genius was officered by an able foreign staff and became not only a dependable source of revenue but an agency for the charting and lighting of the coasts and the inauguration of a postal system. Being national, not provincial, it was, moreover, a means of centralizing the government in the hands of Peking.

Other rebellions threatened the power of the Manchus, especially in Shensi, Kansu and Sinkiang, but these were all suppressed. The Manchu dynasty, indeed, for the moment took on a new lease of life. The able empress-dowager, Tzu Hsi, who had had the good fortune to bear the heir of Hsien Fêng, ruled as co-regent during the minority of her son, the emperor T'ung Chih, and then on his death (1875) obtained the succession for another minor—known by his reign name of Kuang Hsü—and was dominant not only during his boyhood but after her nominal retirement (1889). Unscrupulous, but vigorous and able, she probably prolonged the life of the dynasty.

Increasing Foreign Pressure on China, 1860-94.—The years between 1860 and 1894 were marked by no major crises in China's foreign relations, and Chinese life and culture went on nearly unaltered by the presence of the Westerner. Pressure was steadily accumulating, however, occasional minor clashes occurred, and the stage was being set for revolutionary changes.

From time to time new ports were opened, and through these and the ones previously available foreign commerce was growing. As before 1860, the British continued to lead. In the treaty ports foreign colonies arose, and in some of them special districts were set aside, usually either as "concessions" or "settlements" (some of them dated from before 1860), which, as a development of extraterritoriality, were under the administration of the foreigners, through the consuls and usually a council elected by the foreign tax-payers.

Christian missionaries, both Roman Catholic and Protestant, rapidly increased in number. The first Protestant missionary, Robert Morrison, of the London Missionary Society, arrived in 1807, and under the impulse of the vigorous new life in Protestantism in Europe and America, during the ensuing century representatives of many societies followed—British, American and European. Protestant missionaries emphasized the translation and distribution of the Scriptures and of religious and secular literature, preaching, schools, medical relief and the formation of

churches. They were largely responsible for China's first contacts with Western education and medical science. Roman Catholics reinforced their missionary staffs, emphasizing the winning of converts and the care of children in orphanages. By 1890 Protestant Chinese numbered about 50,000 and Roman Catholic Chinese about 500,000.

Occasional crises arose with foreign Powers and usually resulted in fresh concessions to the Westerner, either in privileges or in territory. The massacre of some foreigners, chiefly French, at Tientsin, in 1870, through anti-Catholic sentiment, and anti-Christian riots in the Yangtze valley in 1890 and 1891 were only the most prominent incidents arising out of the presence of missionaries. Interference by missionaries—usually Catholic—on behalf of converts was a constant source of friction. In 1875 a British exploring expedition was attacked, and an interpreter, Margery, was killed on the border between Burma and Yunnan. Great Britain took the occasion to demand not only redress but the adjustment of other outstanding questions. In the resulting Chefoo Convention (1876) a number of new regulations for trade and official intercourse were agreed upon, and four more cities were opened to foreigners. In the '70s China and Russia nearly came to blows over the occupation by the latter, during a rebellion in Chinese Turkistan, of Ili. By the final settlement (1881) Russia restored all but a small part of the region. In 1881, after prolonged friction, China recognized Japanese jurisdiction over the Liuchiu islands. In the '80s, from difficulties arising out of the extension of French authority over Annam, the desultory Franco-Chinese war broke out. It was terminated in 1885 by a treaty surrendering Chinese suzerainty over Annam. China formally recognized (1886) the British annexation of Upper Burma, with the provision that the decennial tribute-bearing mission should be continued to be despatched to Peking. This fell into abeyance after 1900.

In spite of imperial prohibition, the emigration of Chinese was constant. Chinese had long been settling in adjacent lands to the south—the Philippines, Borneo, Java, the Malay Peninsula, Siam and Burma. In the 19th century the movement was accelerated, and large overseas Chinese communities arose, chiefly in the lands above mentioned. Some of the migration extended much farther, however—to the Pacific coast of the United States, the South Sea islands, Australia, Peru, the West Indies, the Guianas and Central America. Now, as previously, nearly all of the voluntary expatriates came from Kwangtung, Fukien and Chékiang. Much of the emigration after the treaties was under the form of contract labour, which often was thinly disguised slavery. Many abuses were connected with it—kidnapping, and intolerable conditions on shipboard and after arrival. After much agitation and by a succession of steps, by about 1875 the worst evils were eliminated. Chinese immigration to the United States was never under contract, but it gave rise to much ill-feeling. At first welcomed, the Chinese soon met with opposition from white labour, especially in California. Several decades of trouble followed. In part with the acquiescence of China, the United States suspended for set periods the immigration of labourers. After 1900, without the consent of China, that suspension was made permanent.

The growing pressure of the West began slowly to take effect. Before 1895 startling changes in the structure of Chinese life occurred, but here and there were indications that China would not remain as she had been. In the first place, she somewhat grudgingly began to enter into the diplomatic life of the world. In 1866 a Manchu was sent to Europe with Mr. (later Sir) Robert Hart to observe and report. In 1867 Anson Burlingame, who was retiring as United States minister in Peking, was asked to head a mission to present China's case to the governments of the West. Burlingame went first to the United States and there negotiated a treaty (1868) which among other things promised respect for the territorial integrity of China and freedom of immigration of Chinese labourers to the United States and reciprocal rights of residence and travel. The latter provisions proved embarrassing when the United States attempted to restrict immigration. From Great Britain and France the mission obtained assurances that pressure would not be applied inconsistent with

the independence and safety of China. In 1870, after visiting several courts, and while in St. Petersburg, Mr. Burlingame died and his colleagues returned to China. The mission was much criticized, especially for Burlingame's optimistic speeches, but—with the exception of a much earlier one to Russia (1733)—it was China's first formal embassy to that West with which she must henceforth deal. Before 1880 resident envoys had been appointed to most of the leading capitals of the world. In 1873 and again in the early '90's, the foreign envoys in Peking were given audience by the emperor, but always with a subtle suggestion that they were considered as coming from tributary states. Not until 1894 were they received on the basis of full equality.

In the '70s, at the instance of Yung Wing, who had graduated from Yale in 1854, the Chinese government sent several scores of youths to the United States to be educated, but in 1881 a conservative brought about their recall. Two government schools were founded to train men for diplomatic service. By 1894 telegraph lines and a few miles of railway were built, and some attempts were made to reorganize China's naval and military forces and to construct coast defences according to western models. Chinese officialdom was, however, far from enthusiastic about such innovations. It was especially reluctant to borrow western capital, for foreign interference might follow.

The Sino-Japanese War and the Beginning of Rapid Changes.—China could not hope long to remain semi-isolated. The Occident was continuing to expand, Japan, at China's very doors, was rapidly adopting and adapting western culture, and the Middle Kingdom must sooner or later adjust itself to the new world.

The beginning of rapid change was brought by war with Japan. Korea had long been in an ill-defined position of vassalage to China. Japanese, on the other hand, had invaded the peninsula at least twice, the latest occasion having been in the last decade of the 16th century. With her re-organization in the '60's and '70's, Japan once more adopted an aggressive foreign policy, and in doing so came into conflict with China, for the latter, under the advice of Li Hung-chang, was inclined—with some vacillation—to assert more actively than in the past her authority as suzerain. Japan refused to recognize China's suzerainty and the two nations came to blows over the despatch of troops by both to put down an insurrection in Korea. War was declared Aug. 1, 1894, and China was quickly and overwhelmingly defeated. By March 1895, the Japanese had successfully invaded Shantung and Manchuria, had captured Weihaiwei and Port Arthur, fortified posts which commanded the sea approaches to Peking, and the Chinese sued for peace. By the resulting treaty (of Shimonoseki) China recognized the independence of Korea, ceded to Japan Formosa, the adjoining Pescadores Islands, and the Liaotung Peninsula (in Manchuria), agreed to pay an indemnity of 200,000,000 taels, opened four more ports to trade, and promised a satisfactory treaty of commerce. Russia was not disposed to see Japan make gains which would threaten her own ambitions in the Far East, and, backed by her ally, France, and by Germany—who professed fear of the "Yellow Peril"—protested against the cession of the Liaotung territory. Japan had no other recourse but submission, and the retrocession to China was made in return for a face-saving increase in the indemnity.

The victory of Japan was the signal for a scramble among the Powers for leases, concessions and special privileges. The weakness of the Middle Kingdom had been unmistakably disclosed and for a few years it looked as though the Powers, driven by earth-hunger and fear of each other, would partition it. Russian, French, British and German bankers angrily contested for shares in the loans through which China was to pay the Japanese indemnity. In 1895 Russia obtained permission to carry the Trans-Siberian railway directly across Manchuria instead of by the longer all-Russian route of the Amur and Ussuri. France secured a "rectification" of the frontier in the Mekong valley and railway and mining privileges in China. Great Britain, alarmed, demanded and received concessions on the Burmese frontier. Rumours were soon afloat (1896) of further grants to Russia in Manchuria and of a promise to that same Power of a lease on

Kiaochow bay in Shantung. Russia, too, extended her influence in Korea. In Nov. 1897, German forces seized Tsingtau, giving as an excuse the murder of German missionaries in Shantung, and the following March that port and land controlling Kiaochow bay were leased to Germany for 99 years, and railway and mining concessions in Shantung were assured her. Russia made the German seizure of Tsingtau the signal for the occupation of Port Arthur and Talienswan (Dalny), and in March 1898 a portion of the Liaotung peninsula, which included these two ports, was leased to her for 25 years. Within a few weeks France was given a 99 years' lease to Kwangchow-wan in Kwangtung and Great Britain acquired Weihaiwei "for so long a period as Port Arthur shall remain in the occupation of Russia." Great Britain also acquired a 99 years' lease on an additional portion of the Kowloon promontory, opposite Hongkong.

Concurrently with the seizure of these leaseholds, the Powers delimited "spheres of interest," by which they meant, by implication, prior rights to provide capital for the development of mines and railways, and the promise of non-alienation of territory to another power. In case China should be partitioned, spheres of interest might become formal annexations. In 1897 France secured from China a "declaration of non-alienation" of Hainan to any third Power. In 1898 Great Britain obtained a similar declaration for the provinces adjoining the Yangtze, France for the provinces bordering on Tongking, and Japan a promise that none of Fukien would be alienated to any Power whatsoever. Germany claimed Shantung as her sphere and Russia the territory north of the Great Wall. In 1899 Russia and Great Britain agreed not to interfere in each other's preserves. Great Britain, too, exacted from China a promise that the inspector-general of the maritime customs should be of British nationality, at least so long as the trade of Great Britain exceeded that of any other country. Several of the Powers, too, took advantage of the general scramble to demand "concessions" and additions to existing settlements in some of the treaty ports.

Still another form of the struggle for a slice of the Chinese melon was the competition for the privilege of providing capital for railways. The details of the story are extremely complicated, but in general the results were that Russia acquired a monopoly on railway building in Manchuria; Belgian financiers—behind whom France and Russia were suspected to stand—provided the money for the road from Peking to Hankow; Germans furnished the capital for lines in Shantung and for the northern section of the road from Tientsin to Pukow (on the Yangtze, opposite Nanking), Britons for the southern half of the road and the line from Shanghai to Nanking, and France was granted concessions for railways in her sphere of interest—Kwangtung, Kwangsi and Yunnan. An American syndicate was given the concession for a road from Hankow to Canton, but the Belgians later acquired a controlling interest in the company, and the Chinese, irritated, bought back the grant. The French got from the Russo-Chinese bank the contract for a road connecting Taiyüanfu with the Peking-Hankow line, and a Franco-Belgian syndicate the contract for a line from Kaifengfu to Honanfu. Mining concessions, which need not be enumerated here, were also obtained by various foreign groups.

To prevent the threatened disruption of China three major and widely different attempts were made. One was by the United States. In the autumn of 1899 John Hay, the American secretary of State, asked from England, France, Russia, Germany, Japan and Italy assurances that within their respective spheres of interest they would not interfere with any treaty port or vested interest, that no preferential harbour dues or railway charges would be given their subjects, and that the Chinese government should collect the customs duties and only according to the Chinese tariffs. This "open door policy" was not, strictly speaking, new, but was founded upon the most favoured nation clauses. Nor was it entirely disinterested. The United States held aloof, to be sure, from the scramble for leases and concessions, but this was partly because Americans were too engrossed in developing the virgin resources of their own land to engage in ventures abroad. On her recent acquisition of Hawaii and the Philippines, however, the

United States had awakened to a livelier interest in the Far East, and did not wish doors to be slammed in the faces of her merchants and bankers. All the Powers assented to the American note, although Russia did so with slight reservations.

The other major attempts to save China were by the Chinese themselves. After the war with Japan clubs sprang up advocating "reform"—reorganization on the Occidental pattern. That, so the members urged, had been the secret of Japan's victory. The great viceroy, Chang Chih-tung, came out with a widely read pamphlet, "Learn," urging reform, although without the abandonment of the best of China's heritage. Some of the extremists, notably the brilliant but erratic K'ang Yu-wei and his disciple, Liang Ch'i-ch'ao, a master of Chinese style, obtained the ear of the emperor and for a little over three months in the summer of 1898 edict after edict poured forth from Peking ordering some of the changes which the radicals desired. Compared with what was to happen in the next 25 years, these were moderate enough, but at the time they seemed revolutionary. The civil service examinations were to be reformed, new schools with western as well as Chinese subjects were to be founded, western military methods and equipment were to be introduced, and steps taken looking toward a national army based on conscription, reforms in the courts of law were projected, a government bureau to translate foreign works, and a ministry of arts, commerce and agriculture were to be established, patent and copyright laws were to be introduced and rewards offered to authors and inventors, annual budgets of receipts and expenditure were sanctioned, and many sinecure offices were abolished.

Skilled statesmen might have succeeded in carrying through these reforms without provoking a major crisis, but the young emperor knew little of the world of men outside his palace walls, and his radical advisers had little or no experience in government. The inevitable storm was, therefore, intensified, and in Sept. 1898 the empress dowager suddenly intervened and inaugurated a third attempt to save China—by a return to the conservative *status quo*. The *coup d'état* was precipitated by the emperor's plan to thwart the reactionaries by placing restrictions on the empress dowager and executing her most loyal henchman, Jung Lu. Information seems to have come to Jung Lu through Yüan Shih-k'ai, and Tzu Hsi acted promptly. On Sept. 22, 1898, she reassumed the reins of government. She kept the emperor a virtual prisoner and but for the Powers might have had him assassinated. As many reformers as could be apprehended were executed, and most of the reform decrees were annulled. Tzu Hsi attempted to restore the government as it had been and to strengthen it to resist foreign encroachments.

The Boxer Uprising 1900.—On the heels of the conservative reaction, and in part as a consequence of it, came a blind attempt, largely popular, but sanctioned by the extremists, to oust the foreigner once and for all. In 1898 and 1899 unrest was widespread, induced partly by the talk of reform, partly by the aggressions of the Powers, and partly by the vigorous reaction led by the empress dowager. The government, in an attempt to provide for the national defence against foreign aggression, ordered the revival of the village train-bands or militia, and put the plan into effect first in the north-eastern provinces. Into these train-bands came many of the local rowdies and here and there disorderly secret societies affiliated with them. The members practised rites which they believed would make them invulnerable to bullets and came to be known to foreigners as "Boxers"—a loose translation of the Chinese name for the bands, I Ho Tuan or I Ho Ch'uan, "Righteous Harmony Bands" or "Righteous Harmony Fists." One of the favourite mottoes of the Boxers was "Protect the country, destroy the foreigner." By the autumn of 1899 the Boxers were beginning to persecute Christians—as "secondary foreign devils"—especially in Shantung, where the anti-foreign Yü Hsien was governor. The Powers, alarmed, brought pressure, and while they obtained the recall of Yü Hsien, that worthy was soon appointed to the governorship of Shansi, and unrest increased. An English missionary was murdered the last day of 1899, and by the following June the attacks on Chinese Christians became more frequent and foreigners were in grave

danger. In early June (1900) an unsuccessful attempt of the Powers to throw additional troops into Peking aggravated the situation, and when, on June 17, foreigners seized the Taku forts to open the way to Tientsin and Peking, the storm broke. Against the counsel of saner heads, the empress dowager ordered all foreigners to be killed. The German minister was murdered, and the other foreign ministers and their staffs, missionaries, and hundreds of Chinese Christians were besieged in the legation quarter and in the catholic cathedral in Peking. Scores of Roman catholic and protestant missionaries and thousands of Chinese Christians were done to death, principally in Chihli, Shansi and Manchuria. The Powers declared that they were not waging war on China, but were simply seeking to rescue their nationals and to suppress the Boxers, and the viceroys in the Yangtze valley and the south accordingly remained neutral and endeavoured to repress anti-foreign outbreaks within their jurisdiction. That attitude was also taken by high officials in most of the west and north. The disorders, therefore, were chiefly confined to the north-east. An international force captured Peking on August 14, the Court fled to Hsianfu, and the foreign troops proceeded to loot the capital and then to relieve scattered groups of missionaries and Christians who had been standing siege and to disperse the Boxer remnants.

Although the Powers had not declared war on China, they deemed a formal settlement necessary to exact reparation and to guard against a recurrence of the outbreak. After negotiations, which were prolonged by disagreements among the victors, in Sept. 1901 a protocol was finally signed. This document provided for the punishment, by China, of some of the officials held chiefly responsible, for memorial monuments for some of the murdered foreigners, for formal missions of apology to Berlin for the death of the German minister, for the suspension for five years of civil service examinations in towns where foreigners had been killed or mishandled, for the prohibition for at least two years of the importation of arms and ammunition, for an indemnity of 450,000,000 taels, to be paid in 39 years and to be secured by the revenues of the imperial maritime customs, for the fortification and policing by foreigners of the legation quarter, the razing of the Taku forts, and the maintenance by foreign troops of communication between Peking and the sea, for edicts against anti-foreign agitation, for the amendment of the existing commercial treaties, and for transforming the foreign office (Tsungli Yamen) into the chief of the ministries of State, under the name of the Wai Wu Pu.

1900-11. The Era of Change to the Overthrow of the Manchus.—The Boxer year inaugurated momentous changes. The empire was clearly at the mercy of the Powers, and foreigners acted as though they were living in a conquered country. With the exception of Manchuria, encroachments on Chinese sovereignty were not as marked as in 1898 and 1899. The Russians continued their aggressions. The disorders of 1900 had spread to Manchuria and thither Russia quickly despatched large bodies of troops, ostensibly to protect her subjects and her investments. The Russian forces ruthlessly suppressed all opposition and occupied much of the three provinces. Late in 1900 an agreement between China and Russia promised the latter extensive control in southern Manchuria and was modified only on protest from the other Powers. Both Great Britain and Japan were alarmed, the former because of her general fear of Russia in the East and the latter because of the threat to Korea, where Russian machinations were increasing. In defence against the common foe, the Anglo-Japanese alliance was formed (Jan. 30, 1902). Russia, subjected to pressure from these two Powers and the United States, promised to respect the commercial rights of all nations, and agreed with China (April 8, 1902) gradually to withdraw her troops from Manchuria. However, she found pretexts for delays and sought from China, in return for evacuation, compensations which would have strengthened her hold on the debated territory.

Great Britain, the United States and Japan sought to check Russia. Japan was especially concerned and strove by direct negotiations with St. Petersburg to obtain recognition of her interests in Korea and the promised evacuation of Russian troops from Manchuria. Russia was obdurate and Japan had recourse to arms (Feb. 1904). In the ensuing months the Japanese captured

Port Arthur, drove the Russians out of southern Manchuria, and destroyed the Russian fleets. In 1905 President Roosevelt proffered his good offices, hostilities were suspended, and by the resulting Treaty of Portsmouth (Sept. 5, 1905) Russia recognized Japan's interests in Korea, transferred to Japan her rights in the Liaotung Peninsula, ceded to her the southern section of the Manchurian railway, and the southern half of Sakhalin, and both

Powers agreed to withdraw their troops from Manchuria, to use the railways in Manchuria, except those in the Liaotung Peninsula, only for economic and industrial and not for strategic purposes, and not to obstruct "measures common to all countries which China may take for the development of the commerce and industry of Manchuria."

BY COURTESY OF THE Y.W.C.A.

COTTON MILL WORKER AT SHANGHAI

inserted which Japan later used in an effort to close the door in Manchuria to other foreign railways than her own.

The war merely substituted Japan for Russia in southern Manchuria, and the former was no more scrupulous in respecting China's rights than was the latter. Many Japanese contended, indeed, that having spent blood and treasure for Manchuria they had better rights there than the Chinese. By the annexation of Korea (1910) Japan moved her boundary to the south-eastern edge of Manchuria and strengthened her interests in Kirin and Fengtien, the southern two of the three provinces. Almost immediately after the war complaints began to be made that Japanese authorities in Manchuria were discriminating against the nationals of other countries. Great Britain's hands were tied by the Anglo-Japanese alliance—renewed in 1905—but the United States, in contrast to a pronounced friendliness during the war which President Roosevelt had almost cemented into an alliance, actively strove to secure the open door in Japan's new sphere of influence. Americans offered to buy parts of the railways. The Department of State supported American capital in seeking a railway concession in Manchuria, and in 1909 Secretary of State Knox proposed to neutralize the Manchurian roads by a joint loan from the Powers for the purchase of existing lines and the construction of new ones. The Knox proposal brought Russia and Japan together in a convention (1910) to safeguard their respective interests in the three provinces.

The suppression of the Boxer outbreak by the Powers and the subsequent war between Japan and Russia seriously weakened China. The governmental machinery, which had worked fairly well as long as China had not been in intimate touch with nations as powerful as herself, proved inadequate to meet the strain imposed by the coming of the Occident. The Manchus would have to show unusual ability if they were to save their throne, and the Chinese if they were to avoid anarchy.

After 1900 and especially after 1905 both Chinese and Manchus set about the reorganization of the country. Even the most conservative could not fail to read the signs of the times, and the empress dowager, doubtless reluctantly and with many misgivings, attempted to direct the reform which she could no longer avert. In 1902 the Court returned to Peking and the empress dowager set herself to win the friendship of the foreigners, addressing herself especially to the ladies of the legations. Much more important was the sanction which she gave to decrees which sought to aid and to regulate the introduction of Western civilization.

In 1902 orders were issued to remodel public instruction by

the creation of new schools and by the introduction of Western subjects to the curriculum. In Sept. 1905 a decree was promulgated abolishing that most characteristic feature of the old educational system, the civil service examination. Partly as a result of these orders and partly in consequence of the general movement for reform, schools teaching Chinese and Western subjects sprang up by the thousand. The old examination stalls were razed and on some of the sites rose buildings dedicated to the new learning. Many a temple was converted for educational purposes. By the end of 1910 there were 35,198 government schools, with 875,760 pupils. Protestant mission institutions, once the unpopular representatives of a new learning, were now thronged and new ones were opened. Students by the thousand flocked to Japan, there to study in modern schools, and hundreds went to Europe and America. When, in 1908, the United States announced its purpose to return a portion of its share of the Boxer indemnity, the sums remitted were set aside for scholarships to enable Chinese to study in America. With the new schools came a flood of literature treating of Western ideas, and publishing houses, notably the Commercial Press, arose to give it circulation.

With educational reform went efforts to put the country in a better state of defence. The foreign drilling of the northern army continued; throughout the country troops were trained in the new ways, greater honours were paid to military officers, and in 1906 steps were taken toward the creation of a national force as contrasted with the older provincial ones. Naval construction was not seriously undertaken, although societies were started to collect funds for that purpose (1907) and in 1909 a naval commission was sent abroad to study methods of reorganization.

In 1910 slavery was abolished, but since that institution was never as prominent in China as in parts of the Occident, the step did not entail marked revolution. Vigorous efforts were made to stamp out opium, an imperial edict of Sept. 1906 inaugurating the campaign. The British government, under whose protection was much of the foreign trade in the drug, in 1907 agreed to reduce the importation concurrently with the progressive abolishment of the domestic growth of the poppy, at a rate which would extinguish the trade in ten years. The restriction on poppy-growing proved so much more rapid than was anticipated that in 1911 Great Britain agreed to the complete exclusion of the foreign drug from the provinces where the culture had ceased.

Governmental reorganization was also undertaken. In 1902 a commission on juridical reform was established and in 1905 reported recommending the modification of the laws. As a beginning, torture, except in criminal cases, and certain cruel forms of punishment were ordered to be abolished. The reorganization of laws and judiciary was not sufficiently thorough-going, however, to cause the Powers to dispense with extraterritoriality. The reform of the currency was discussed, but nothing effective was accomplished, and with the appearance of new coins the previous confusion became worse confounded.

Most important of all the governmental reforms was the attempt to introduce a constitution with representative assemblies. In 1905 a commission was sent abroad to study constitutional methods, and on its return, in 1906, a promise was made to introduce a parliamentary form of government. That same year, as a preliminary, changes were made in the organization of the central administrative boards in Peking. Among these was an attempt at a more direct control of the imperial maritime customs service, which resulted in the retirement of Sir Robert Hart from the inspector-generalship in which he had given such noteworthy service.

In Aug. 1908 an edict promised the convocation of parliament in nine years, but the death of the emperor and of the empress dowager in November of that year brought postponement. The new emperor, a nephew of the childless Kwang Hsü, was an infant of two-and-a-half years, and his father, Prince Chun, was appointed regent. The new reign was given the title of Hsüan T'ung. Shortly after its beginning the regency was deprived of the support of one of the strongest Chinese by the forcible retirement of Yüan Shih-k'ai, as a punishment, so rumour had it, for his alleged betrayal of the regent's brother, the late emperor, in 1898.

Constitutional reform was only delayed by the change in rulers, and that briefly. In 1909 provincial assemblies met, chosen by a limited electorate, and in Oct. 1910 the national assembly convened, one-half of it elected and half appointed by the Throne. The national assembly demanded the right to legislate, but for the time could merely gain the promise of the convocation of a parliament with legislative powers in 1913 rather than in 1917.

Along with changes in education and government went other sweeping alterations in the nation's life. Several of the railways authorized before 1900 were constructed, bringing great modifications in transportation. Foreign shipping increased on the coastal waters and the Yangtze, telegraph lines were extended, and the business of the post office multiplied. Foreign commerce more than doubled in the decade after 1901, and foreign merchandise penetrated to the remotest hamlets. The numbers of missionaries rapidly increased, and both the catholic and protestant communities showed a phenomenal growth.

The Passing of the Manchus.—In 1912 the rising tide of change swept aside the Manchus. Ever since the conquest in the 17th century most of the Manchus had lived in comparative idleness, supposedly a standing army of occupation, but in reality inefficient pensionaries. All through the 19th century the dynasty had been declining and in the death of the empress dowager it lost its last able leader. In 1911 the emperor was an infant and the regency utterly incompetent to guide the nation through the stormy waters ahead. The unsuccessful contests with foreign Powers had shaken not only the dynasty but the entire machinery of government. The ferment of new ideas was already weakening the ancient wineskins, and only strong and wise leadership could prevent loss to both. "Reform" was in the air and secret revolutionary societies in and out of China were agitating for still more radical action. Under the circumstances almost any incident might have toppled the Manchus off the throne.

The chain of events immediately leading to the revolution began with the signing (April 5, 1911), with a four-power group of foreign bankers, of the Hukwang railway loan agreement for the construction of roads in Central China. The Peking government decided to take over from a local company a line in Szechwan, on which construction had been barely begun, and to apply part of the loan to its completion. The sum offered did not meet the demands of the stockholders and in Sept. 1911 the dissatisfaction, mishandled, boiled over into open revolt. On Oct. 10, in consequence of the uncovering of a plot in Hankow which had little or no connection with the Szechwan episode, a mutiny broke out among the troops in Wuchang, which is regarded as the formal beginning of the revolution. The mutineers soon captured the Wuchang mint and the arsenal at Wuchang, and city after city declared against the Manchus. The regent, panic stricken, granted the assembly's demand for the immediate adoption of a constitution, and urged Yüan Shih-k'ai to come out of retirement and save the dynasty. Yüan, after much hesitation, accepted on his own terms, and at the end of October took the field at the head of the northern armies. In November he was made premier.

Had Yüan acted vigorously he might have suppressed the uprising and so have delayed the inevitable. He dallied, however, and by the end of the year 14 provinces had declared against the Manchus, in several cities Manchu garrisons had been massacred, the regent had been forced out of office, a provisional republican government had been set up at Nanking, and the arch-revolutionist, Sun Yat-sen, had returned from abroad and had been elected president.

In December, Yüan agreed to an armistice and entered upon negotiations with the republicans. On Feb. 12, 1912, the boy emperor was made to abdicate the throne in a proclamation which transferred the government to the people's representatives, declared that the constitution should henceforth be republican, and gave Yüan Shih-k'ai full powers to organize a provisional government. The Nanking authorities agreed that the emperor was to retain his title for life and to receive a large pension. To unify the country, Sun Yat-sen resigned the presidency and Yüan was chosen in his place. Li Yüan-hung, who had come into prominence

in Wuchang in the initial stages of the rebellion, was elected vice-president. A provisional constitution was promulgated in March 1912 by the Nanking parliament, and in April the government was transferred to Peking.

The republic, established with such startling rapidity and comparative ease, was destined to witness the progressive collapse of national unity and orderly government. The causes for this chaos were, in the main, three. In the first place, traditional processes were being repeated. The demise of every dynasty had been followed by civil strife, in which rival military chieftains struggled for the throne. The disorder usually lasted for decades, and once, after the downfall of the Han dynasty, was prolonged for nearly four centuries. The peaceful transfer of power to Yüan Shih-k'ai under the guise of a republic for a time mitigated the struggle and even seemed to have averted it. Yüan, however, as we shall soon see, did not prove strong enough to hold the country together. So far (1928) no one else has come as near to success as did he, and the country has broken up into ever smaller fragments, most of them ruled by military chieftains. Figures came and went from the political stage with bewildering rapidity, and after Yüan's death (1916) the political map has never been the same two years in succession.

In the second place, the chaos was accentuated by new ideas from the West. For 2,000 years a change in dynasty had been followed by no very great alteration in the form of government. Each ruling house took over, with some modification, the laws and institutions of its predecessors. This, however, was no longer possible. The governmental machinery which had on the whole worked better over a longer period than any other ever devised by man for so numerous a people, was being abandoned. It was ill adapted to the new conditions, and theoretical radicals, imbued with Occidental ideas, and militarists tended to ignore it or to modify it more greatly than at any time since the Han. Such thorough-going political experimentation meant chaos, and new institutions were not quickly evolved for so enormous a section of mankind.

In the third place, the disorder was increased by the interference of foreigners. Japan was vitally concerned in the fate of her huge neighbour. Her population was steadily increasing, no adequate relief could be had through emigration, and her only recourse was to add to her income by engaging in industry and commerce. If she were to do this, she must have access to raw materials, including coal and iron, and to markets. For these she most naturally looked to the adjoining continent, and especially to China. Her life depended, therefore, upon keeping open the door into China, and it is not surprising that she sought to control portions of the republic and at times meddled in Chinese politics. To Japan were added the Western Powers, especially Russia. Beginning about 1922, but especially after 1925, Russian communists sought to extend their influence into China and to foment the kind of revolution which they had achieved at home.

It must be noted, however, that foreign activities helped to bring union as well as disunion. Resentment against the foreigner was the one issue on which the vocal elements of the nation could unite; railways and telegraph lines—both of foreign origin—helped to bind the country together, and the foreign-controlled imperial maritime customs service and the foreign-organized postal system were the only governmental agencies which continued to function over all the country.

The Republic Under Yüan Shih-k'ai.—For four years Yüan Shih-k'ai was able to delay the further disintegration of China. He faced no easy task. The radicals, who in August 1912 took the party name of Kuomintang, regarded him with suspicion, and, obtaining a majority in the parliament which assembled in 1913 under the provisional constitution of 1912, demanded a type of government in which the legislature should be supreme and the president a figurehead. Rival military leaders were beginning to appear, and grave financial difficulties faced a government whose fiscal machinery, already decrepit, had been disturbed by the revolution. The confidence of the Powers, moreover, was not yet given the new régime.

In the face of all these difficulties Yüan for a time achieved

marked success and gradually restored in the provinces the authority of the central government. In April 1913, after prolonged negotiations, he concluded a "reorganization" loan with a financial group representing Great Britain, France, Russia, Germany and Japan. The loan, a large one, was secured by a lien on Chinese revenues, chiefly on the income from the salt monopoly—now put under foreign supervision. His financial position and the moral support of the Powers thus assured, Yüan proceeded to defy the members of the Kuomintang. The latter had sought to block the loan and saw in its conclusion grave danger to themselves. They continued obstructionist policies, and, as Yüan still prevailed, in the summer of 1913 some of them, including Sun Yat-sen and Huang Hsing, declared a "punitive" expedition against him and for a while held Nanking. Yüan promptly put down the rebellion, and, after obtaining the ratification of the articles of the "permanent" constitution which had to do with choosing the president, and being elected under them (Oct. 1913), he outlawed the Kuomintang (Nov. 1913) and unseated its members of parliament. A few weeks later he disbanded what remained of parliament, replacing it with an administrative council selected by himself. In March 1914 the provincial assemblies were dissolved. A new constitution, framed by a body controlled by Yüan, was promulgated in May 1914. The president's power was greatly strengthened, his term was lengthened to ten years, and he might be rechosen by the Council of State or control the election of his successor. In 1914 Yüan performed the imperial ceremonies in the Temple of Heaven at the winter solstice. He seemed to be winning against the opposition and in 1915 prepared to take the further step of having himself formally chosen and proclaimed emperor. In the summer of 1915 the Chou-an Hui, made up chiefly of Yüan's adherents, organized an energetic propaganda for the restoration of the monarchy, and, in spite of some plain-spoken objections, notably by the distinguished scholar, Liang Ch'i-ch'ao, and the disapproval of the vice-president, Li Yüan-hung, and even of some of his former supporters, Yüan, after going through the form of a "referendum," and, as precedent demanded, declining the initial requests of the Council of State announced the restoration of the monarchy. Opposition continued to develop, however, for radicals were not slow to denounce this usurpation by their arch-enemy, and military chiefs had no desire to see Yüan seize the coveted prize. Moreover, Japan, backed by Great Britain, Russia and France, cautioned delay. Yüan accordingly postponed the coronation. By the end of 1915 rebellion, led by Ts'ai Ao, had broken out in distant Yunnan, and by the end of March 1916 so many of the provinces had declared their "independence" that Yüan's remaining friends advised him to resign the presidency. This Yüan declined to do, but he did consent to the restoration of parliamentary government. Yüan's concessions merely strengthened the opposition and the Kuomintang leaders established a provisional government at Canton and elected Li Yüan-hung president. At this juncture (June 6, 1916) Yüan fortunately died, prostrated by chagrin and rage.

With Yüan removed, the country appeared quickly to unite. Li Yüan-hung, unopposed, succeeded to the presidency; Tuan Chi-jui, appointed by Yüan in the last few weeks of his life, continued as premier and brought to the support of the new government some of the northern military chiefs, and the parliament of 1913, reassembling, brought back to Peking many of the Kuomintang. The government seemed to be further strengthened by the election to the vice-presidency of Fêng Kuo-chang, dominant in the lower part of the Yangtze valley. The very strength of the new government was, however, its weakness, for it was made up of elements which were fundamentally discordant and which any crisis might set at loggerheads. This crisis was to grow out of international reactions in which China was inextricably involved.

Foreign Relations, 1911-17.—The revolution did not immediately bring marked change in China's foreign relations. Tibet and Outer Mongolia, at best never too firmly attached to the empire, took the opportunity afforded by the shift in governments to effect their virtual independence, and Great Britain in the

former case and Russia in the latter were not slow to attempt to extend their influence over territories which abutted so directly upon their own. China recognized the autonomy of Outer Mongolia in return for the acknowledgment of her suzerainty but she was less pliant in yielding to British ambitions in Tibet. On the whole, the Powers made little objection to the establishment of the republic, although recognition was more prompt on the part of some than of others.

The outbreak of the World War, however, brought serious difficulties. With Europe absorbed in internecine strife, Japan saw a golden opportunity to extend her power in China. The Anglo-Japanese alliance afforded her a welcome excuse for seeking to eliminate Germany from the Far East. Accordingly, in Aug. 1914 she despatched an expedition to Shantung, and, with the co-operation of a small British force, captured Tsingtao and the other German possessions in the province. Through her premier, Japan averred that she had "no ulterior motive, no desire to secure more territory, no thought of depriving China or other peoples of anything which they now possess," but she disregarded Chinese neutrality and protests, and later went beyond any privileges ever granted to Germany in demarcating a railway zone and establishing a civil administration along it.

The occupation of the German properties in Shantung was only a beginning. In Jan. 1915 Japan presented to Peking a formidable array of 21 demands in five groups.

1. In Shantung, China was to agree to any transfer of German possessions to Japan that the latter might obtain. China was not to alienate to a third power any territory in the province; she was to declare additional cities to be open ports and was to grant certain railway privileges.

2. In south Manchuria and eastern Inner Mongolia, the lease of Port Arthur, Dairen (Dalny), and the railways were to be extended to 99 years. Anywhere in these regions, Japanese might lease land and travel or reside. There were, too, demands for mining and railway privileges, and for the Japanese control of loans and the employment of Japanese official advisers.

3. The Han-yeh-p'ing Company, the largest Chinese iron-mining and smelting concern, was to be made a Chino-Japanese enterprise and China was not to sell her interest in it without Japan's consent.

4. China was to promise not to cede or lease to any third power any harbour, bay or island along her coast.

5. China was to employ Japanese as advisers to the central government; the police departments in certain districts were to be jointly administered by Japanese and Chinese; China was either to buy 50% or more of her munitions from Japan or to establish a Sino-Japanese arsenal, which was to use Japanese materials under the direction of Japanese; Japanese were to be granted the privilege of buying land in the interior for schools, hospitals and churches; certain railway concessions in the Yangtze valley were to be promised, and Japan was to be allowed to scrutinize all proposed loans of foreign capital for mines and works in Fukien.

Japan attempted to keep the demands secret, but they became known and a wave of indignation swept over China and criticism was publicly and vigorously expressed in Great Britain and the United States. Encouraged by this support, Yüan Shih-k'ai offered stout resistance. The Japanese were constrained to make important concessions, but they had the upper hand and knew it, and after weeks of negotiations presented an ultimatum, to which China, helpless, had no recourse but submission. By a series of treaties and exchange of notes China agreed to the first three groups, with important modifications in her favour; group four was not mentioned, and group five was reserved for further negotiations except for a promise from China that no nation should be permitted to construct a dockyard, a coaling station or a naval base on the coast of Fukien.

In Aug. 1916 trouble broke out between Chinese and Japanese troops on the Manchurian-Mongolian border which led to fresh demands upon China—demands from which, however, Tokyo subsequently largely retreated. Then, in Feb. and March of 1917, Japan made secret arrangements with Great Britain, France and Italy, whereby these Powers assured her their support to her de-

mands at the peace conference for the former German holdings in Shantung.

China's Entrance into the War and Further Internal Difficulties.—As the World War progressed, pressure was brought upon China to induce her to enter the struggle on the side of the Allies. In Feb. 1917 the United States invited the Chinese government to follow its example in protesting against Germany's submarine campaign and severing diplomatic relations, and the Franco-Japanese secret Notes of March 1, 1917 promised Tokyo's support to the effort to induce Peking to take the step. On Feb. 9 the Chinese foreign office sent warning to Germany, and on March 14 broke off diplomatic intercourse.

The question of whether China should go further and declare war on Germany now aroused a discussion which severed the bonds, never strong, between the discordant elements which had made up the national government since the death of Yüan Shih-k'ai. The country was once more plunged into civil strife—strife from which, stimulated by other factors, China is now (1928) only beginning to emerge. The premier, Tuan Chi-jui, wished China to enter the war and convened a conference of military governors which on April 26 voted for that action. A few days later the cabinet unanimously voted to support it. Members of parliament, however, alarmed at the attempt to coerce it into assent and by rumours of secret agreements between Tuan's group and Japan, held back. On May 19 parliament declined further to consider the question until the cabinet had been reconstituted. Tuan countered by demanding of the president the immediate dissolution of parliament. On May 23 the president dismissed the premier, and the latter, taking refuge with northern military leaders in Tientsin, declared his defiance. Among Tuan's supporters were the military governors of several of the provinces north of the Yangtze, and these now proceeded to set up a provisional government with an aged ex-vice-roy, Hsü Shih-chang, as titular head. Since the recalcitrants had military control of the north, Li Yüan-hung found himself in sore straits. He called to his assistance the swash-buckling Chang Hsun, who with his army had been sitting astride the Tientsin-Pukow railway, and, at his insistence, dismissed parliament (June 12). Chang Hsun was, however, not content to play Li's game, and on July 1 electrified Peking by declaring the restoration of the boy emperor. Li, defenceless, sought refuge in the Japanese legation. The northern military chiefs were, however, no more favourably disposed to Chang Hsun in power under the thin disguise of a Manchu restoration than they had been to parliament. Tuan, therefore, led an army to the capital, ostensibly to defend the republic, Chang Hsun capitulated (July 12), and the young emperor was consigned once more to the tranquil dignity of his court without a kingdom. Tuan Chi-jui now resumed the premiership with enhanced prestige and power. Li Yüan-hung had so greatly lost face that he could not well reassume the presidency, and retired to private life. He was succeeded by the vice-president, Fêng Kuo-chang. Tuan and his supporters now being in control in the north, they carried through their purpose which had precipitated the crisis, and on Aug. 14, 1917 formally declared war on Germany.

The Kuomintang members of the dismissed parliament denounced the Peking government as illegal, and, under the leadership of Sun Yat-sen, in Sept. 1917 organized a provisional government which they declared to be the only constitutional one in China. The Powers did not grant it recognition, however, and it maintained a precarious and chequered existence, usually with headquarters at Canton.

In the north Tuan Chi-jui and his supporters, the so-called Anfu group, were for some years in the ascendant. To give the appearance of constitutionality, an assembly was convened which revised the law for elections to parliament. This having been duly promulgated, a new parliament was chosen in time to deal with the quinquennial election of the president. Fêng Kuo-chang was passed over because he could not work with Tuan Chi-jui, and the elderly Hsü Shih-chang was selected (Sept. 4, 1918).

China's Part in the War.—In the meantime the World War was drawing to a close. China's internal discord and financial straits were such that she could take no active part in the struggle.

She permitted, it is true, the recruiting of about 175,000 of her citizens for labour battalions for service behind the lines in France, Mesopotamia and Africa, but the initiative was taken and the transportation and organization were conducted by the Allies. She seized, too, the German and Austrian vessels interned in her ports, and chartered some of them in the service of the Allies.

China gained slightly by her entry into the war. She cancelled the unpaid portions of the Boxer indemnities due to Germany and Russia and was permitted to suspend for the time payments on the sums due to the Allies. She was assured, moreover, a seat at the Peace Conference.

In contrast with these gains, however, was an increased control by Japan. In Nov. 1917 the United States, in an effort to adjust her difficulties with Japan, entered upon the Lansing-Ishii agreement (terminated Mar. 30, 1923), by which she recognized that because of "territorial propinquity . . . Japan had special interests in China," and so seemed to have delivered the latter over to the island empire. A "war participation board" with a Japanese adviser and an "arms contract" (Jan. 1918) betokened the growth of Japanese influence at Peking, and in May 1918 Japan and China entered into an agreement for defence against possible invasion from the north. The Anfu clique around Tuan Chi-jui concluded agreements with Japan for the construction of railways in Shantung, Manchuria and Mongolia (Sept. 1918) and borrowed extensively from the Japanese on the security—some of it extremely dubious—of railways, mines, forests, telegraphs, taxes and bonds.

The Peace Conference.—To the Peace Conference which terminated the war the Chinese sent an able delegation representing, by a strange but characteristic anomaly, both the Peking and the Canton governments. The delegation asked not only for the restoration to China of the former German properties in Shantung, but for the cancellation of spheres of influence, the withdrawal of foreign troops, post offices and wireless and telegraphic communications, the abolition of consular jurisdiction, tariff autonomy, the relinquishment of leased territories, and the restoration of foreign concessions and settlements. China was, however, doomed to disappointment. The American delegation favoured the restoration of the Shantung properties, but against it were the agreements of 1917 between Japan and the European Allies. By the Treaty of Versailles, therefore, Japan was confirmed in the possession of her holdings in Shantung. The remaining questions were held not to come within the purview of the conference. So great was the indignation of the younger educated Chinese at this settlement that the pro-Japanese Peking government could not but instruct the Paris delegation to refuse to sign the treaty with Germany, and two members of the cabinet who had been most prominent in the loan negotiations with Japan were forced to resign. In 1919, too, a very effective nation-wide boycott against Japanese goods was instituted.

China was not, however, to emerge from the war without some gains. She obtained membership in the League of Nations by signing the treaty with Austria, for that document did not contain the objectionable Shantung-clauses, and in her separate treaty with Berlin the German share of the Boxer indemnity and German extraterritorial privileges were cancelled. A significant breach had been made in the wall of foreign "rights" in China.

The Washington Conference.—After the war America continued her active participation in Chinese affairs by bringing about (1920) a financial consortium whose purpose it was to assume international control of all further foreign loans to China, and so to prevent the granting of special privileges to individual nations.

In 1921 and 1922, moreover, the United States called the Washington Conference (*q.v.*) and China again had the opportunity to lay her case before the world and to ask for the elimination of the special privileges that foreigners enjoyed within her borders. Not all the agreements and treaties which arose out of the conference affected China, but the Chinese question loomed larger than any other except possibly that of disarmament. The most important actions, in so far as they concerned China, were as follows:—

1. The treaty limiting naval armaments and fortifications had the effect of confirming Japan in the domination of the north-eastern coast of Asia. No sea power could now hope to penetrate by force through her curtain of islands to the coast of China.

2. Nine Powers agreed by treaty to respect the sovereignty, independence and territorial and administrative integrity of China, to give China opportunity to develop a stable government, to maintain the principle of equal opportunity in China for the commerce and industry of all nations, and to refrain from taking advantage of conditions in China to seek special privileges that would abridge the rights of subjects or citizens of friendly states.

3. The customs schedule of duties was within four months to be raised to an effective 5%, and provision was made for the convening of a special tariff conference and for the periodical readjustment of the customs tariff.

4. A board of reference was to be established in China to which questions connected with the enforcement of the "open door" and equal railway rates could be referred.

5. A resolution expressed the sympathy of the Powers with China's desire to see removed "immediately or as soon as circumstances will permit existing limitations upon China's political, jurisdictional and administrative freedom," and provided for the early establishment of a commission to inquire into the practice of extraterritoriality in China and the progress in judicial reforms.

6. On Jan. 1, 1923, foreign postal agencies in China were to be abolished.

7. The Powers declared their intention to withdraw their armed forces from China as soon as China "shall assure the protection of the lives and property of foreigners," and resolved that as soon as China should request it they would appoint representatives to see whether these conditions had been fulfilled.

8. There were resolutions concerning radios in China.

9. There were resolutions concerning the unification of the railways of China, the employment of foreign technical experts for these railways and the Chinese Eastern railway.

10. The conference expressed the hope that immediate steps would be taken by China to reduce her military forces and expenditures.

11. There was provision for machinery by which the Powers were to be notified of all treaties, conventions and agreements with or concerning China.

The Washington Conference also afforded Japan and China an opportunity to come to an understanding over the thorny Shantung question. Following the signing of the Treaty of Versailles, Japan had made attempts to adjust the dispute, but always on conditions which had been repulsed by the Chinese. Now, however, Japan adopted a much more conciliatory attitude, and an agreement was reached whereby the former German holdings in Shantung were to be returned to China. However, the Japanese retained a share in some mines in the province and large commercial interests and land-holdings in Tsingtao. China borrowed from Japan on the security of the railways the sum needed for the redemption of the roads, and during the continuation of the loan the roads were to have a Japanese traffic manager.

Several of the promises made to China at Washington were carried out. The foreign post offices were discontinued at the designated time. A special conference on the tariff convened in Peking in Oct. 1926 and, going beyond the assurances previously given, permitted the consideration of the entire question of tariff autonomy. Because of the disintegration of the Chinese government, the gathering broke up before a treaty was framed, but the foreign delegates agreed to the removal of tariff restrictions and consented to the putting into effect the Chinese national tariff law on Jan. 1, 1929. The Chinese for their part promised to enforce the national tariff law and to abolish *likin*, long obnoxious to foreigners, on the same date.

The promised commission on extraterritoriality reported in 1926, describing the status of consular jurisdiction as then practised and of Chinese laws and administration of justice, outlining the changes desired before extraterritoriality would be removed.

CHINESE CITIES: ANCIENT AND MODERN ASPECTS

1. Street canal, Soochow (or Suchow), province of Kiang-su, about 50 miles northwest of Shanghai. Soochow, like Venice, is built on numerous islands, separated by canals
2. Peking, pylon outside the water gate. Peking is surrounded by a wall with 16 city gates
3. Canton. Scene along water-front of Pearl river, on east bank of which Canton is situated. The river swarms with trading vessels and Chinese junks
4. Street scene, Shanghai. The buildings are chiefly two or three storeys high
5. Bird's-eye view of Dalren, a great Manchurian port on Liao-tung peninsula, about 20 miles north-east of Port Arthur
6. Typical business street in Canton. Although some of the streets are not wider than 5 ft., Canton is comparatively clean and orderly

CHINESE NATIVES OF SEVERAL CLASSES

1. An old man, bearing a striking resemblance to portraits of Confucius
2. Mongolian chieftain, riding a yak
3. Mohammedan sheik, Central China. There are over 10,000,000 Muslims in China
4. A Lama (priest of Buddhist sect) and his dog, Lama temple, Peking
5. Mongolian type
6. A Cantonese family of the better class
7. Houseboat child, wearing a life-preserver—a usual part of her apparel
8. Mongolian family of the tribe Gimut-Dorgje, before their tent
9. A Manchurian family, Peking

and suggesting immediate mild modifications of extraterritoriality and the correction of abuses.

Japan, moreover, continued conciliatory. While she declined to accede to the Chinese demand, made in 1923, for the abrogation of the agreements of 1915, she entered upon no new marked aggression. In 1927 and 1928, to be sure, when anti-foreign agitation and civil war endangered her nationals she at times acted vigorously, and she seemed to be entering upon a new advance in Manchuria, but she was much more careful to respect Chinese sensibilities than she had been during the World War.

The Powers also seemed about to remit the unpaid portions of the Boxer indemnity. The United States acted finally in May 1924, and Great Britain, France, Japan and Russia took preliminary steps looking toward the same end. All plans for remission, however, called for the allocation of the funds to educational or other cultural projects and there was danger that they would be used to build up educational "spheres of influence."

Domestic Politics After the World War.—While China was making progress toward regaining the special privileges which had been wrested by the Powers, internally her government was rapidly disintegrating.

At the close of the World War, it will be recalled, Hsü Shih-chang was in the presidential chair and Tuan Chi-jui was in control. A separate government was maintained at Canton, largely by members of the Kuomintang, under the leadership of Sun Yat-sen. For a time Sun was ousted from Canton by a Kwangsi faction, but he was restored by Ch'en Ch'ung-ming, and in April 1921 he was elected "president of the Chinese republic" by such members of the parliament of 1913 as could be got together. He professed to be the head of the only legal government in China and prepared to invade the north. In 1922, however, he fell out with Ch'en Ch'ung-ming, for a time was in exile, and although in 1923 he was able to return, he secured only a precarious foothold in Canton and a part of Kwangtung. Most of southern China was a medley of petty factions and quarrelling war lords.

Conditions were little better in the north. In 1920 the outstanding leaders were Wu P'ei-fu, his titular superior, Ts'ao Kun, and Chang Tso-lin, the master of wealthy Manchuria. In the summer of 1920 these three united to drive Tuan and the Anfu leaders out of power. Wu P'ei-fu and Chang Tso-lin could not long co-operate, and in 1922 Wu defeated the latter and drove him back into Manchuria.

Wu now took steps which he hoped would unify the country. Hsü Shih-chang resigned the presidency, Li Yüan-hung was re-instated in that office, and the parliament of 1913 was recalled to Peking. Thus the last officers on which the entire country had seemed to unite were put back into power.

Hopes for a unified China, however, proved illusory. Funds were insufficient, cabinets unstable, parliament venal, and in June 1923 Li Yüan-hung again fled from the capital. In Oct. 1923 parliament, probably as the result of heavy bribes, elected Ts'ao Kun to the presidency and a "permanent" constitution was promulgated.

In 1924 Wu and Chang renewed their war, Wu was defeated, and Ts'ao Kun was ousted. This *bouleversement* was due to the defection of one of Wu's subordinates, Fêng Yü-hsiang. Fêng, for several years a rising military figure, was a protestant Christian, and due to his zeal a large proportion of his forces professed the same faith. His army was noted for its iron discipline and for the absence of the vices usually attendant upon camp life. Upon Wu's defeat, Chang and Fêng conferred at Tientsin with Tuan Chi-jui, and late in Nov. 1924 Tuan assumed the office of chief executive (not president) and announced a provisional government. A "reorganization conference" was called but accomplished nothing. Sun Yat-sen came north to have a part in the new régime, and on March 12, 1925, died in Peking.

Fêng and Chang could not co-operate any more successfully than had Chang and Wu, and in 1925 Fêng, since 1923 master of Peking, aided by the treachery of one of Chang's generals, compelled Chang to retire once more to Manchuria. Chang Tso-lin eliminated the traitor, however, and early in 1926 he and his quondam enemy, Wu P'ei-fu, united by their common hatred of

Fêng Yü-hsiang, joined to drive the latter out of Peking and into Mongolia.

In the late spring of 1926 a new and startling factor appeared on the scene in the form of a revived Kuomintang. Sun, in dying, did more for the Kuomintang than he had been able to do when alive. He was a visionary, not an administrator or organizer, and as long as he was its head his party could not hope long to achieve national success. Immediately after his death, however, his party made him a national hero, and in his last will and testament to the Chinese people and in a book which he had written, the *San Min Chu I*, it found a programme. This programme was threefold: democratic government, a higher standard of living for the masses, and the recovery of the rights granted to foreigners. Pending the unification of the country the full realization of democracy was to be postponed and dictatorship by a single party, the Kuomintang, was to be substituted. Stress was, accordingly, laid on the last two objectives. Better living conditions for the proletariat were to be achieved in part by the organization of labour and peasant unions. The movement against the "unequal" treaties, growing ever since the Peace Conference, had been accentuated by events in 1925. On May 30 of that year the British-commanded police of the international settlement in Shanghai fired into a crowd of students who had gathered before the police station to demand the release of their comrades arrested for agitation in connection with a strike in Japanese-owned cotton mills. Anti-foreign and especially anti-British agitation spread like wildfire over China. Aggravated by a skirmish between Shameen, the foreign settlement in Canton, and the Chinese, an anti-British boycott was instituted which was particularly effective in the south.

Russian communists, chief of whom was Borodin, led in framing and executing the Kuomintang's programme. They had originally been called in as advisers by Sun Yat-sen and the small Chinese communist party had been incorporated into the Kuomintang. Russians, moreover, drilled the officers of the Kuomintang or nationalist army. The leaders of the Kuomintang, among them Mrs. Sun Yat-sen, Sun Foo, a son of the late leader, T. V. Soong, Mrs. Sun's brother, and Eugene Ch'en, born at Trinidad and educated in Great Britain, were not all in sympathy with the communists but hoped to utilize them to achieve the nationalists' aims.

In the summer of 1926 the nationalist armies, led by Chiang K'ai-shek, began a triumphant march northward and by the coming of winter they had driven Wu P'ei-fu into Honan and practically eliminated him, were in possession of the Wu-han cities—Hankow, Wuchang and Hanyang—and the Kuomintang had moved its capital there. The victories had been achieved as much by skilful propaganda as by force of arms. Wherever the nationalist forces came, trained agitators directed popular sentiment against the treaties and foreign merchants, and against Christian schools, churches and hospitals as "imperialistic." Enmity was chiefly directed against the British, but Americans also suffered, and protestants were more in disfavour than were catholics. Kuomintang agitators also organized labourers and peasants to make exorbitant demands of employers and landlords, and in some places, notably in Hunan and Hupeh, a reign of terror followed in which many of the propertied class were dispossessed and even executed.

Educated Chinese, weary of the long civil strife and smarting over China's feeble position among the nations, hailed the advance of the Kuomintang as the harbinger of better days. That advance continued with amazing rapidity and by March 1927 the Chinese had taken over the British concessions in Hankow and Kiukiang, British and American merchants and missionaries were being evacuated from much of the nationalist territory, Sun Chuan-fang, recently strongly entrenched in Chêkiang and Kiangsu, was in full flight, his armies a disorganized rabble, and only strong forces of foreign marines kept the nationalist armies out of the foreign settlements in Shanghai. The northern military chiefs, alarmed, had put themselves under the direction of Chang Tso-lin to stem, if possible, the oncoming flood.

The Kuomintang, however, broke down on the eve of its tri-

umph. On March 24, 1927, nationalist troops, entering Nanking on the heels of fleeing remnants of the northern forces, savagely looted foreign dwellings, robbed foreigners, killing three or four of them, and further loss of foreign life was prevented only by the fire of the foreign gunboats on the Yangtze. One of the effects of the outrage was to widen the breach between the communists and moderate elements of the Kuomintang. Within a few weeks Chiang K'ai-shek had set up a government at Nanking which denounced the radicalism of the Wu-han leaders.

The nationalist advance was halted by these internal dissensions and the party continued to divide. By autumn 1927 the anti-communist reaction was in full swing, Borodin and other Russian advisers were ousted from Wu-han, and in many places Chinese communists were being hunted down and executed. In Dec. 1927 a conference of the leaders of the Kuomintang was held at Shanghai to try to heal the breach, but it came out strongly against the communists and ordered the closing of Russian consulates in nationalist territories. An attempt at a communist *coup d'état* in Canton was ruthlessly suppressed, and Russian as well as Chinese suspects were executed. South of the Yangtze the country was in sorer straits than at any time since the T'ai Ping rebellion. No effective central government existed, bandits and lawless soldiers terrorized the populace, prices were soaring, and liberals were disillusioned and disheartened.

In the north-east, Chang Tso-lin continued dominant. The autumn of 1927 witnessed the failure of a joint attack on him by Feng Yü-hsiang—now back in Honan and professing nationalist sympathies although independent of the Kuomintang—and by Yen Hsi-shan, the governor of Shansi. An attempt of the northerners to retake Nanking was, however, unsuccessful.

The opening of 1928, then, found China in greater disorder than at any time since the 17th and possibly since the 13th century.

In 1928, however, a better day seemed to dawn. The nationalists reorganized under moderate and conservative leaders, and with headquarters at Nanking, began a new northward advance. Chiang K'ai-shek led, in co-operation with Feng Yü-hsiang and Yen Hsi-shan. A serious clash with Japanese troops occurred in May in Tsinanfu and a partial re-occupation of Shantung by Japan followed. In spite of this, however, the nationalists pushed on and in June entered Peking. Chang Tso-lin was killed by a bomb as he was retiring into Manchuria, and his son, Chang Hsüeh-liang, succeeded to the command of his forces. Because of Japanese opposition, Manchuria did not formally join the nationalists, but Chang Hsüeh-liang was given a place on the chief council of the Nanking government. The major armed opposition to their rule having been eliminated, the nationalists sought to consolidate their gains and by the close of 1928 were making encouraging progress. They moved the capital from Peking (now renamed Peiping—"Northern Peace") to Nanking, and in October set up an administration re-organized to conform to Sun Yat-sen's programme, with Chiang K'ai-shek as the ranking official. While much of the country still paid little real heed to Nanking, and factional and personal jealousies had by no means disappeared, finances were improving and the foreign minister, C. T. Wang, was vigorously pushing for a revision of the "unequal" treaties.

The Progress of the Cultural Revolution.—Preoccupation with political developments under the republic must not be allowed to obscure the changes, some of them much more significant, in other phases of China's life. These are covered more fully elsewhere in these pages, but the picture would not be well-rounded if they were not also mentioned here. The impact of the Occident was affecting every phase of the nation's culture and the process was hastened by the collapse of the ancient political structure. Social customs were passing, including many of the older forms of politeness. The patriarchal family was beginning to disintegrate, and youths were insisting upon making their matrimonial arrangements independently of parental control. Women were demanding greater privileges, often in bizarre ways. By a revolution comparable only to that which occurred in Europe when the vernaculars were substituted for Latin, a digni-

fied form of mandarin was taking the place of the older literary style. New religious and philosophical ideas were abroad and old ones were revived. Nothing, whether Chinese or foreign, was too well established to be questioned. Factories were beginning to supplant the older handicrafts and labour unions the ancient guilds.

These changes were, naturally, most marked in the cities, particularly those of the coast, and here and there in the rural districts the old China survived almost unaltered. More than any other section of the nation, the students were committed to the new ways. They were intensely nationalistic, and led in boycotts against foreigners. They were self-assertive and their unions not only attempted to dictate school policies but to be heard on national issues. More than any other class they were departing from the traditions of the elder China. China, led by her intellectuals, was in process of reorganizing her culture and fundamental convictions more thoroughly than at any time since the Chou dynasty.

BIBLIOGRAPHY.—For Chinese works see LITERATURE.

General Histories. The longest is J. A. de Moyria de Mailla, *Histoire générale de la Chine* (1777-85). Others of fairly large dimensions are Henri Cordier, *Histoire générale de la Chine* (1920); D. Boulger, *A History of China* (1881); Wieger, *Textes historiques* (1904); and J. MacGowan, *Imperial History of China* (1906). Among the shorter histories are F. L. H. Pott, *A Sketch of Chinese History*, 3rd ed. (1915); Gowen and Hall, *An Outline History of China* (1926); K. S. Latourette, *The Development of China*, 4th ed. (1929); and E. H. Parker, *China, Past and Present* (1903).

Special Phases of Chinese History.—For the ancient period see F. Hirth, *The Ancient History of China* (1908); E. H. Parker, *Ancient China Simplified* (1908); H. Maspero, *La Chine antique* (1927); and E. Chavannes, *Mémoires historiques de Se-ma Tsien* (1895-1905). For biography see H. A. Giles, *A Chinese Biographical Dictionary* (1898). For recent history see Bland and Backhouse, *China under the Empress Dowager* (1910); W. J. Hall, *Tseng Kuofan and the T'ai Ping Rebellion* (1926); H. T. Hodgkin, *China in the Family of Nations* (1923); S. K. Hornbeck, *Contemporary Politics in the Far East* (1916); S. H. Hsu, *China and her Political Entity* (1926); P. S. AESTHETIC DEVELOPMENT

In northern China, mainly in the basin of the Huang Ho or Yellow river, there slowly emerged in late prehistoric times a focus of civilization destined eventually to make its influence felt in all the neighbouring regions, both continental and insular. Apart from certain well shaped stone implements and fragments of a coarse, unglazed pottery, few vestiges of the Chinese Stone age culture have thus far been found. An important exception is the recent discovery in northern China of a painted ware with analogies in Turkistan and regions still farther west.

Chinese Bronze Age.—It is only with the acquisition of bronze that a distinctly Chinese civilization first appears. So far no trace has been found of evolution out of an earlier copper period like that which took place in the Occident. On the contrary, the bronze objects found in China are all essentially late forms, identical in principle with types which in other lands appear only toward the close of the Bronze age. This great advance in civilization seems to have occurred under the mainly legendary Shang dynasty, the date of whose beginning no one knows, but which terminated about the end of the second millenium B.C. It is, however, with the succeeding largely historical Chou period,

with its long line of priest-kings and its brilliant feudal aristocracy, that the Chinese Bronze age is especially linked. In the present fragmentary state of our knowledge of China during the first millennium B.C., it is only possible to reconstruct the civilization of that time very imperfectly. It may be said, however, that although barbarous in many respects, it was distinguished for colour and richness and the lavish use not only of bronze but also of gold, ivory, jade, featherwork and ornamental textiles. Its designs are pretty certainly a development of the old Neolithic art, retained because of their traditionally sacred character and the belief that any alteration in them would diminish their magical efficacy.

The high artistic quality of this civilization is best exemplified in the great bronze ceremonial vessels used in connection with the ancestor worship of the nobility. These, for grandeur of form, dignity and ornamentation, and mastery of technique, have never been surpassed, and command the admiration of students and art-lovers the world over.

The Ch'in Dynasty.—The later portion of the Chou period witnessed a great social and economic development, which in time undermined the archaic feudal system. The 3rd century B.C. saw its entire overthrow, along with that of its venerable but long since impotent hieratic dynasty, by the vigorous western fief of Ch'in. The ruler of the latter forcibly united the hitherto loosely federated States into a centralized empire, of which he declared himself first emperor. Of the artistic achievements of his powerful but short-lived dynasty we know but little. A nearly contemporary work states that large bronze statues were then cast, and certain types of vessels of that material have been ascribed to the period, with hardly sufficient reason. That it was an epoch of extraordinary magnificence, there is no doubt. The Ch'in dynasty collapsed little more than a decade after its establishment, having fulfilled, however, its historic mission of assuring once for all the cultural unity of China.

The Han Dynasty.—Out of the general welter of war which followed, there emerged in a few years the great dynasty of the Han, which reigned over the empire, with but one brief interval, from 206 B.C. to A.D. 220. This period of over 400 years is a most important one, in art as in other respects. Then first appeared numerous hitherto unknown culture elements of fundamental importance to the Chinese civilization of later times.

Of its architecture the records have much to say, but nothing has survived save certain foundation mounds and city and boundary walls of rammed earth. Sculpture in stone now first made its appearance, in the form of low reliefs and figures of men and animals set up about tombs; here some connection with the art of western regions may be suspected, for it was just at this time that direct contact with the Occident was first established. Painting underwent a great development, its materials, instruments and technique becoming fundamentally what they have since remained. Of its achievements, only certain archaic delineations of human figures on funerary tiles are known; but it would seem mainly to have depicted scenes of battle, the hunt, and court and domestic life, with but little attempt at landscape. Only in the 2nd century A.D., toward the close of the dynasty, did the names of individual artists begin to be recorded.

The pottery of this period also shared in the great aesthetic evolution then taking place. Glaze, known for millenniums in the Occident, now first appears in China, and the great Han mortuary vessels, sometimes inspired by bronze forms or encircled by bands of vigorous naturalistic scenes in relief, are well known to collectors. The first tentative essays in the direction of porcelain are likewise to be ascribed to this period. Clay figures of men, women, animals, houses and utensils, found buried in tombs, throw much light on the life of the time. The decorative arts, like those of the jeweller and the lapidary, also underwent a rich and striking development; in connection with the latter it may be noted that seals, usually cut in jade or some other hard stone, long known in western lands, now first appeared in China.

The downfall of the Han dynasty, in the 3rd century, led to a condition of disunion and civil war, which lasted for nearly 400 years. Yet, in spite of this, great progress was made in all the arts. In architecture, probably toward the close of the period,

arose the practice of uptilting the corners of roofs, regarded by Westerners as so characteristically Chinese. Paintings on silk, still chiefly of human figures but displaying attempts toward landscape, are known to us through copies by later artists. Pottery was further improved and diversified in form, ornamentation and technique, and true porcelain appears, apparently as a direct evolution out of the ware of the Han dynasty.

THE EFFECT OF BUDDHISM

The New Religious Factor.—It was, however, in religious rather than secular art, that the period achieved its greatest aesthetic triumphs. This was due to the introduction of Buddhism from India. The effect of this upon China and her neighbours throughout all subsequent history has been incalculable, and may well be compared to the effect on Europe of the introduction of Christianity. The famous early Buddhist sculpture of Gandhara, in north-western India, reached its maximum development about the 2nd century, but in its pure form spread only as far as eastern Turkistan. The art which now developed in northern China under the Toba Tatar or North Wei dynasty (A.D. 386-534) was no direct outgrowth of this. It must have flowered locally under the stimulus of the new religious faith, although naturally finding inspiration for certain of its elements in Indian, Iranian or even Hellenistic ideas which reached China by the great Central Asiatic caravan-routes. It is best exemplified by the remarkable series of sculptured grottoes of Yün-kang in northern Shansi and Lung-mên in Honan, in regions where the North Wei power successively centred. Its best work is characterized by slinness of figure, rhythmic grace of curve and that passionless, spiritual calm and benevolence which are the essence of Buddhism.

Very little later, mainly under the local Liang dynasty (502-556), the new influence also reached China by the sea-route through the Straits of Malacca. This latter movement, originating chiefly in southern India, brought with it an art little affected by that of Gandhara, but reflecting rather that of the great Maurya dynasty of the 3rd century B.C. Among the elements which it introduced were the fluted column and great and vigorously executed winged lions; examples of both these still survive, much mutilated, in the vicinity of Nanking, the capital of the Liang dominions. Little is yet known of this southern Buddhist art of China, partly because of the tremendous destruction of its works wrought by the Taiping rebellion of the middle of the 19th century, but partly too because it has hitherto attracted less attention than that of the north.

The heterogeneous mass of animism, folk-lore, and magic which formed the religion of the masses in feudal days was liberated by the destruction of the nobility, and acquired great influence during much of the Ch'in and Han Dynasties. Gradually organized into the system known as Taoism, it borrowed from Buddhism not merely its temples, festivals and whole paraphernalia of worship, but also its art, notably its sculpture. Its works, however, are much cruder in every way, and artistic merit of any sort is exceptional.

The T'ang Dynasty.—After this long period of disunion and war, toward the close of the sixth century, China was again united under the brilliant but short-lived Sui dynasty (A.D. 589-618). This in turn was succeeded by that of the T'ang (A.D. 618-906), whose long sway vied with that of the Han as one of the greatest epochs of Chinese history. Under its earlier rulers, China had nothing to fear from comparison with any realm on earth, whether that of Byzantium, of Sassanid Persia or the newly founded power of Islam. Intercourse with the Occident during much of this time was constant and close, and ideas of every sort travelled both east and west.

Buddhist sculpture now attained its highest pitch; naturalism replaced conventionality, and heads, instead of reflecting an impersonal and purely spiritual ideal, became individual portraits. Painting also underwent a noteworthy development. To this period belongs Wu Tao-tzû, greatest of all Chinese painters, whose style has exerted enormous influence upon all later times, not only in China, but also in Japan. Two schools appeared, a northern and a southern, and landscape was now seriously developed. Almost

all the authentic existing T'ang dynasty paintings are religious in character; but fortunately a very few secular examples survive, while others are known through copies by artists of later periods.

In pottery also the T'ang period reached a higher stage than hitherto. Glazes were increased in range of colour and texture. The forms themselves are predominantly native, although in some cases they reflect western influences, especially that of Sassanid Persia. T'ang grave figures are well known for their artistic merits as well as their great archaeological interest. Bronze, long since displaced by iron for the manufacture of weapons and tools, was in greater favour than ever in the arts, notably for the casting of Buddhist statues and statuettes, often richly gilt. Ivory from southern China and Indo-China and jade from Turkistan were carved into a variety of ornamental shapes. Although probably already known in principle, engraving on wood now makes its first definite appearance. The T'ang period is also noteworthy for the great extension of Chinese culture which then took place into southern China, till then only partially assimilated, and also into Korea and Japan. The dynasty, after a long period of decadence, came to an end early in the 10th century.

The Sung Dynasty.—After another period of turmoil, which however lasted only half a century, China was again united, under the Sung dynasty, which maintained its sway over the whole country for slightly over a century and a half. Then, through Tartar aggression, its power was restricted for a further similar period to that part of the country situated south of the Yangtse river, until it was finally overthrown by the Mongols about 1280.

During the Sung period the influence of Buddhism greatly declined, being replaced by Confucianism, and probably as a result of this, sculpture became decadent. Painting, on the other hand, reached heights never attained before. Landscape underwent its greatest development, the effort being not to depict a scene exactly, but to reveal its inward spirit and arouse a corresponding emotion. Taoism, through its love of solitude and contemplation, provided Sung painting with many of its most romantic concepts. Thus there arose in China an appreciation of the beauties of nature, later imparted to Japan but unknown in Europe until the 19th century. Authentic pictures of this period, while more numerous than those of the T'ang, are nevertheless very rare. During this extremely artistic epoch, pottery also underwent a great development, losing, it is true, something of the strength and vigour of the best T'ang examples, but acquiring nevertheless a characteristic tastefulness in form and delicacy of finish.

Northern China, controlled by successive Tartar powers during much of the 12th century, was conquered soon after the opening of the 13th by the Mongols who overran so much of the Old World at that time. Half a century later they also subdued the realm of the Southern Sungs, and China was thus reunited under their rule. The art of their time has little to distinguish it from that of the periods before or after, although perhaps in some instances their adoption of Lamaistic Buddhism has left a visible impress. It was then that began that tendency to resort to antiquity for models which later became so pronounced. Shortly after the middle of the 14th century an outburst of popular fury drove out the decadent later Mongols and led to the accession of the Ming dynasty, the last native Chinese ruling house.

THE CONFUCIAN REVIVAL

The Ming Period.—The Ming period (1368–1644) is especially noteworthy for its great achievements in architecture, even to-day hardly appreciated at their real worth. Nearly all the city and frontier walls, paved roads, bridges, palaces, temples and pagodas still existing in China were constructed by the great Ming builders. Next to its architecture, probably the most important work of the Ming period was that accomplished in pottery. Here too inspiration was sought from the earlier epochs, especially that of the T'ang. But original work was done, and Ming celadons, polychromes and blue-and-white ware are well known. It was during the latter half of the dynasty that porcelain was first regularly exported to Europe, although isolated

examples had reached Mediterranean lands far earlier through Arab traders. The sculpture of this time is dull and uninspired, as shown by its best known examples, the colossal figures of men and animals lining the famous avenue to the Ming tombs just north of Peking. Painting not infrequently displays much excellence, but necessarily lacks the interest always aroused by original creative art. Emphasis was placed chiefly upon landscapes and nature studies, and to the Ming artists who industriously copied earlier works we owe by far the greater part of our knowledge of the secular paintings of the T'ang and Sung times.

In the realm of textiles, embroideries, brocades and damasks of high character were produced, and for the first time, perhaps as a consequence of the contacts opened up with the Near East under the Mongols, Chinese rugs and carpets assume a place of importance. In the minor arts also development attained a high level. Ming cloisonné is characterized by a boldness of design and depth of colour never excelled. Much work of a high technical order was done in the carving of jades and other semi-precious stones and ivory, in dignity and beauty often far superior to later examples. In general, the art of this time, perhaps largely owing to the revival of Confucianism with its worship of antiquity, falls far below that of the earlier and truly great periods. These were spontaneous and creative and had a genuine message; while that of the Mings was consciously imitative and sought its mission in trying to bring back to life a long dead past. Like all its predecessors, the Ming dynasty toward its close underwent a rapid process of degeneration and decadence, the central power becoming weaker and weaker until at last it was overthrown in a great rebellion.

The Ch'ing Dynasty.—The vacant throne was swiftly seized by the warlike Manchus, who proceeded to overrun the entire country, and who gave the Empire an enormous expansion. Their dynasty, known as that of the Ch'ing, produced several rulers of first-rate ability; but their genius displayed itself to better advantage in statecraft and war than in the development of the arts. In architecture they did but little in comparison with their predecessors the Mings, perhaps because the latter had left so little to be done. In sculpture, China under their rule displayed little originality, development being mainly in the direction of grotesque perversion of taste and excess of ornamentation. In painting almost no original work of consequence was done, although the copying of earlier works was continued. It was in the field of porcelain that the most noteworthy aesthetic achievements of the Manchu period have occurred. A marked development took place in fineness of texture and elaboration of form and decoration. The greatest work was done in the two decades from 1662 to 1683. During the 18th century the tendency toward elaboration of form and decoration became more and more marked, and some of the pieces of the Ch'ien-lung period have never been excelled in these respects. The weaving of textiles and rugs, the execution of objects of personal adornment and household decoration, as well as carving of every sort, also display this elaborating tendency. With it went a steady deterioration in taste for which no intricacy of design could compensate.

Whether the present turmoil in China will lead to another period of artistic greatness, only the future can disclose.

Other Regions.—Chinese culture spread to Korea and Japan (*qq.v.*), but these were not the only regions into which it was carried. During the early centuries of the Christian era it spread over southern China and gradually made that region definitively Chinese. Indo-China and Tibet, although strongly affected, escaped such complete absorption, partly because of the presence in those countries of strong Indian cultural counter-currents. During the T'ang period, and again under the dynasty of the Mings, the influence of China penetrated far and wide through the Indian Archipelago; Formosa was partially subdued and assimilated, Borneo and the Philippines underwent Chinese contacts of which traces still remain, and even distant Ceylon for a time was a tributary of the Ming emperors.

As so often occurs in cases of culture diffusion, the influence of Far Eastern aesthetic development continues to be widely felt, although moribund or dead in the lands which saw its birth.

Interest in it grows apace, and collections, researches and publications are multiplied. In the light of recent critical study, largely by Chinese and Japanese scholars themselves, it is being found necessary to reduce greatly the extravagant dates claimed by most Far Eastern nations, with no support from contemporaneous history, for the earlier periods of their culture.

CHINA-CLAY, so called because it is an essential ingredient in the manufacture of china or porcelain. It is also known as *kaolin*, a corruption of the Chinese Kau-ling, meaning "High Ridge," the name of a hill east of King-te-chen, whence the earliest samples of the clay sent to Europe were obtained by the Père d'Entrecolles, a French Jesuit missionary in China in the early part of the 18th century. His specimens, examined in Paris by R. A. Réaumur, showed that true porcelain was manufactured from a paste containing two essential ingredients—*china-clay*, a pure white clay, and *china-stone*, a variety of granite consisting mainly of orthoclase felspar. The china-clay confers plasticity on the paste and secures retention of form for the ware when exposed to the heat of the kiln; while the china-stone gives the translucency so characteristic of porcelain. Some of the earliest discoveries of china-clay in Europe were at Aue, near Schneeberg in Saxony, and at St. Yrieux, near Limoges in France. In England it was discovered in Cornwall about the year 1750 by William Cookworthy, of Plymouth; and in 1768 he took out his patent for making porcelain from china-clay and china-stone. These raw materials were found first at Tregonning hill, near Breaage, and afterwards at St. Stephen's in Brannel, near St. Austell; and their discovery led to the manufacture of hard paste, or true porcelain, at Plymouth and subsequently at Bristol.

The china-clay rock of Cornwall and Devon is a granite with its orthoclase felspar decomposed to a soft white powdery substance which, when wet, acquires the characteristic plasticity of clay. The other components of the granite, the quartz and the mica, are unaffected and, although they are subordinate to the decomposed felspar, or kaolin, their presence retains for the rock the appearance of a weathered granite. Although kaolinization can undoubtedly result from weathering, the evidence in this case indicates that the alteration has been effected at a high temperature by vapours carrying fluorine and boron; and minerals containing these elements (e.g., tourmaline and fluor spar) often occur in association with the china-clay. The alteration consists in the removal of the alkalis and the formation of a hydrated silicate of aluminium having the formula $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$. This substance, known as kaolinite (*q.v.*), constitutes the bulk of refined china-clay, the impurities of the commercial article being finely divided quartz and mica (muscovite). It is not possible to remove the whole of these impurities by washing and this accounts for the difference in composition between pure kaolinite and a refined Cornish china-clay as shown by the analyses in the next column.

| | Kaolinite | China-clay |
|-------------------------------------|-----------|------------|
| SiO ₂ | 46.3 | 48.3 |
| Al ₂ O ₃ | 39.8 | 37.6 |
| Fe ₂ O ₃ | .. | 0.5 |
| CaO | .. | 0.1 |
| K ₂ O, Na ₂ O | .. | 1.5 |
| H ₂ O | 13.9 | 12.5 |

(Note: 1% of alkalis in china-clay is equivalent to 8.5% of muscovite.)

The qualities for which china-clay is esteemed in the arts are whiteness and fineness of grain when it is used as a filler for paper or for dressing fabrics; and plasticity and infusibility when it is used as an ingredient of the paste of porcelain manufacturers. The absence of iron (which would be introduced by dark mica) is particularly important from the colour point of view; while the presence of light mica (muscovite) is undesirable since the alkalis thus introduced tend to lower the fusing point. Since in china-stone the felspar is only partially decomposed it contains a much higher percentage of alkalis than china-clay. This makes it more fusible and one of its uses is to impart a glaze to porcelain during the final firing. In order to prepare china-clay for the market the china-clay rock is subjected to the action of a stream of water. The bulk of the quartz and undecomposed felspar is arrested in suitably situated "sand pits," while the clay is carried away in suspension to the "button hole launder," whence it is pumped to the surface and conveyed to the "drags," which are a series of channels so arranged as to catch the coarser impurities. From the drags the clay-water passes to the "micas," a series of pits where the finer particles of mica and quartz settle down. Thus purified the liquid is led into "settling pits," or tanks, in which the finely-divided clay is slowly deposited. When it has acquired sufficient consistency it is dug out in square blocks and transferred to the "drys," i.e., sheds heated by flues, where the moisture is expelled and the china-clay obtained as a soft white earthy substance. The material obtained in the micas is useful for some purposes (e.g., as an absorbent and detergent in oil-refining) and is sold as an inferior china-clay. China-stone is quarried and ground without levigation. The china-clay industry of Cornwall and Devon has attained to large proportions and is very profitable. The output amounted in 1926 to 825,954 tons, three-quarters of which was exported. The number of persons employed was 4,682. The United States takes one half of the total exports. Other considerable importers are Belgium, France, the Netherlands, Germany, Italy and India. (F. H. HA.)

United States.—In the United States kaolins of the type of china-clay are found in North Carolina, Maryland, Delaware, Pennsylvania, Connecticut, Colorado and other States. The principal source of primary kaolin is North Carolina. The clay from this State differs from the true china-clay in having a coarser grain structure and so is more refractory and porous at the same degree of firing. The chemical composition approaches very closely that of typical kaolin. When properly washed, the North Carolina kaolin develops a very good white colour in firing. It is commonly used in conjunction with English china-clay in the manufacture of white earthenware pottery, wall and floor tiles, since it tends to hold the articles straight during the firing process. In addition, there are in the United States large deposits of secondary kaolin, derived from the primary kaolin of the Appalachian region. These are very fine grained and more plastic than the latter but, as a rule, fire to a faint cream colour though there are exceptions which produce a good white colour. Good examples are the deposits at Okahumpka, Fla., and other places in that State, and those of the Dry Branch and McIntyre districts of Georgia. A somewhat different secondary kaolin occurs in South Carolina. There is an increased tendency to replace the imported china-clays by these native plastic kaolins. Further west, in the States of Kentucky, Tennessee, Mississippi and Arkansas the secondary kaolins are changed to still more fine-grained, very plastic and strong clays, the so-called ball clays. A number of these fire to a light colour and for this reason are introduced in large quantities in earthenware and porcelain bodies. The increased use of these clays has done much to reduce the consumption of the kaolinitic type of materials.

In Bollinger county, Mo., white, kaolin-like clays are found which are the residue of decomposed limestone and carry a large amount of fine silica. A peculiar type of an indurated, hard clay, having very nearly the composition of kaolin, is found in Edwards county, Texas, and at King mountain, Nev. These clays require to be reduced to powder before they can be made to develop plasticity. When ground in water they show colloidal properties and dry to a horn-like strong mass. They fire to a pure white colour. The Texas "kaolin" has the peculiarity of producing translucency in bodies in which it is used even though the firing is not carried close to the point of vitrification. (A. V. B.)

CHINAN or **TSINAN**, a large and historic city and the capital of the province of Shantung in North China, $36^{\circ} 43' N.$, $116^{\circ} 37' E.$ Chinan is situated at the northern base of the ancient Highlands of Shantung (near Tai-shan the sacred mountain) where they sink beneath the alluvium of the Yellow river, and along an important spring-line which fostered very early settlement. Its early history is bound up with that of the ancient states of Chi and Lu in the classical (Chou) period and when the present province of Shantung—closely corresponding to the territory of the two feudal states—was created under the Ming Dynasty (1368–1644) Chinan, a natural focus of mountain and plain, was selected as administrative centre. The strategic and economic significance of its site near the main route between Peking and the Yangtze Delta, followed by the Grand Canal, has been much enhanced in recent times. The last great change in the lower course of the Yellow river in 1854 brought it within five miles of the city which controls the long bridge over it carrying the north to south Tientsin–Pukow Railway (completed in 1912). This railway runs parallel to, and fulfils the function once served by, the now dilapidated Grand Canal. Chinan is the junction of this arterial railway with the Shantung Railway running eastwards by way of the Poshan Coalfield to the port of Tsingtao on Kiaochow Bay which from 1898 until 1915 was leased territory in control of Germany and then fell into the hands of Japan. Although by the Shantung Treaty, arranged at the time of the Washington Conference (1922), Japan on certain conditions surrendered Tsingtao to China, her influence and interests in the Shantung Railway are still very strong, as was shown by the despatch of Japanese troops to Chinan in 1928, when the Nationalist armies were advancing northwards. In contact with foreign influences along the two railways, in communication with the sea by a canal fed from the local springs and the market for one of the richest parts of the Great Plain, Chinan has been much affected by Western industrial methods, seen especially in flour milling and cotton manufacture. The city was voluntarily opened to foreign commerce in 1904 and a large "settlement" has grown up in the Shang-pu or trading quarter, outside the west gate of the city. The population is approximately 300,000. In Chinan is situated the Shantung Christian University, one of the largest Union Universities in China and one of the chief centres of medical training.

CHINANDEGA, an important city of Nicaragua, Central America, capital of the department or State of the same name. It is 13m. N.N.E. of the Pacific port of Corinto, on the Pacific railway; population, 14,415. It is 22m. from León and 74m. from Managua, the national capital. Chinandega is the centre of the sugar-producing area of Nicaragua and a high grade of sugar is manufactured and exported to the western United States and to other Central American countries. Corn, rice, potatoes, vanilla and cotton are also grown. Chinandega was partly destroyed by fire during one of the battles of the revolution of 1927 in which American marines and aeroplanes took an active part.

CHINAWARE, a name given to a hard, translucent pottery. (For UNITED STATES CHINAWARE see p. 554.)

Earthenware is sometimes quite thin, and it is a common error not to discriminate between this and the ware which is properly called china. A simple test for china is its translucency, which allows the outline of a finger to be seen if held between a piece of ware and the light. Another and more accurate test is that of applying red ink to the ware *under the glaze*. If the ink is absorbed, then it is considered that the ware is not china. A por-

tion of the glaze must be thoroughly removed before the ink can be applied.

The actual meaning of "vitrified" causes some trouble and the following is the definition: "Vitrified pottery is non-porous; unvitrified pottery is porous." "Vitrified china" has been defined as follows: "Vitrified china is glazed chinaware having a white body and burned to such a temperature that a dense, practically non-absorbent body is produced." "Practically" is a much abused

FROM BOURRY, "TREATISE ON CERAMIC INDUSTRIES" (SCOTT, GREENWOOD & SONS)

MAKING CHINAWARE ON THE "JOLLEY." A MOULD OF ONE SIDE OF THE ARTICLE TO BE MADE IS FIXED TO THE MACHINE AND MADE TO REVOLVE HORIZONTALLY. PREPARED CLAY IS PLACED IN THE MOULD AND SHAPED BY THE TOOL

adverb, and one is left wondering whether or not a slightly absorbent ware with a white body would pass as "vitrified."

Porcelain, which may be regarded as synonymous with china, is not easily defined in scientific terms, for several specimens of ware, which may be correctly regarded as true porcelain, will vary in actual composition. Dr. J. W. Mellor, F.R.S., has said that the most practical definition he could give is the following: "Porcelain is a body which in moderately thin layers is translucent."

CHIEF CENTRES OF PRODUCTION

Many countries have a justifiable pride in the china they produce; there are special characteristics attached to the composition of the "bodies" (the ware itself) and the decoration; they have beauties of their own and comparison is not possible.

The pottery industry has attracted the patronage of royalty and of governments. It is well known that the ex-*kaiser* had a practical interest in the production of pottery, while the porcelain works at Sèvres are the property of the French Government. For years the world has known The Royal Copenhagen Potteries and in the Far East an even greater interest has been shown for centuries.

Commercially, the chief centres of production, with international importance, are the potteries of Limoges (France), Staffordshire (England), Czechoslovakia, Germany (Thuringia and Bavaria) and Japan. Copenhagen (Denmark) produces a very fine china, but this, although sold commercially, is not strictly a competitive production.

England.—Bone china, the porcelain in which bone ash is an important constituent, is made almost entirely in England, and it is claimed that it is more durable than the felspar china of the Continent of Europe.

This type of porcelain was introduced by the famous potter, Josiah Spode, of Stoke-on-Trent, in 1799. Alexandre Brogniart, director of the national factory at Sèvres, referring to this, said: "Spode produced a better porcelain than any that had yet been made in England. He endeavoured to equal the soft porcelain of Sèvres, which his paste closely resembled. He introduced, or at any rate perfected, the use of calcined bones in the body of the ware." Spode's formula has since been adopted by all the leading manufacturers throughout the five towns in North Staffordshire, and also by the Coalport, Derby, and Worcester factories.

There are 53 manufacturers of china in England, and the greater part of these have their factories at Longton, one of the "five towns" mentioned above.

France.—There are about 42 china factories in Limoges, France, owning approximately 127 ovens, and a large export trade is done.

Czechoslovakia.—Felspar china is produced in large quantities in Czechoslovakia, in the district of Karlovy Vary, Teplice and Liberec (Reichenberg), where there are 62 factories, the largest being at Karlovy Vary. Three-quarters of the yearly output is exported. The United States is the largest customer, while England has received large quantities; but the British import duty on translucent or vitrified pottery has naturally caused a falling off in this trade. The neighbouring countries (Austria, Hungary, Rumania, Poland, etc.) take about 25% of the porcelain produced in Czechoslovakia. The conditions in the factories are somewhat different from those in England or France, boys and girls running about with bare feet. These young workers acquire great skill and carry out work that in other countries would be done by older people. A young girl in Czechoslovakia may be capable of making and fixing handles to cups at the rate of 700 per day.

Germany.—The German industry produces a large proportion of the world's domestic and industrial porcelain, but, according to a report of the industry published in 1927, only 66% to 75% of the capacity of the manufacturers is being utilized. The German potters considered various ways and means for improving trade, and co-operative advertising, standardization of patterns and grades, and price fixing agreements were suggestions put forward. All of these have been adopted by various industries in many countries; in the pottery industry standardization finds great favour in the United States. The export trade of Germany showed a decrease in 1926. Home consumption, too, decreased, being only 34% of the production, as compared with 44% in 1925.

Japan.—Some of the ware of Japan has a world-wide reputation and is distinctly oriental in its decoration; but the Japanese are rapidly copying Western methods, and the decorations of their commercial products are often distinguished from the wares of European countries only with difficulty. They have realized that in order to sell in another country, they must decorate their ware to appeal to the "taste" of the potential buyers. America is the best customer of Japan for porcelain, and is reported to take more than one-third of the total exports.

The centre of the Japanese porcelain industry is at Nagoya. Although modern machinery is employed, the decoration is largely done in the homes of the people. There are also some small crude establishments where china is made, although it is difficult to apply the term "crude" to any pottery establishment, for to the modern eye a factory producing a good ware may only appear to

is said to be the principal contributing factor, particularly in sustaining exports of copies of European designs; but the ware of native characteristics makes an appeal to Western people apart from the price, and is in no sense competitive.

RAW MATERIALS

The raw materials needed for the manufacture of china are china clay or kaolin, china stone, bone and felspar.

China Clay.—This mineral is found in many parts of the world. China clay is said to have resulted from the decomposition of granite through many centuries. Its main constituents are silica and alumina, and may be described generally as a white, amorphous powder. The clay is not usually mined in the ordinary way, but is washed down from the sides of the mine by huge jets of water thrown down out of hose pipes at a high pressure. The water brings down the fine clay to the bottom of the mine, where any sand is allowed to settle out. The watery mixture of clay is then pumped up to the ground level, and run through a series of troughs, known as "micas," where it undergoes a process of levigation. It is the china clay that gives plasticity to the mixture of materials used by the potter.

China Stone.—This is an important ingredient in the china "body," and it is mined by inserting explosive charges in holes drilled by compressed air boring machines.

The stone has four recognized qualities or grades: hard purple (a white, hard rock with a purple tinge); mild purple (similar but softer); dry white or soft (a soft white rock); buff (similar to dry white, but with a slight yellow tinge).

Silica is the principal constituent, amounting to over 80% in the two purple and the buff varieties, and about 74% in the dry white. Alumina is the next important ingredient, amounting to about 18% in the dry white and from 7 to 10% in the other varieties. The most effective constituents are the alkalis and lime which make up the balance of the composition. China stone gives the china "body" its translucency owing to its felspar content. Its function, hence, is that of a flux.

Bone Ash.—This, as already stated, is used in the English china industry, where the "bone china" is almost exclusively produced. Animal bones are used and, owing to its vast business of cattle rearing and slaughtering, South America is the chief source of supply. The bones are calcined and ground to a fine powder.

Felspars.—The felspars are silica compounds of alumina and alkalis (chiefly potash and soda), with small proportions of iron oxide, lime and magnesia. Norway is the principal source of supply, producing about 40,000 tons per year, but large quantities are found in Czechoslovakia, whose annual production is about 30,000 tons. Canada is growing in importance as a felspar producing country, although the production fell to 26,000 tons in 1925, after reaching over 44,000 tons in 1924. The production in 1926 was a little short of that in 1925.

The Norwegian felspar is largely used in Europe. The mineral is exported both in lump and as a powder.

Czechoslovakia is also an exporter of felspar, sending out about 6,000 tons yearly, chiefly to Germany. The export trade of Canada is increasing, and is in the region of 30,000 tons a year.

MAKING THE WARE

The "Slip."—The "slip," it should be explained, is the china clay and other ingredients mixed with water to a thin consistency. Metallic impurities, which would spoil the finished ware, are removed by a series of magnets, which, in one method, are arranged in what is known as a "cascade," i.e., the watery mass flows over small falls, the metallic parts being retained by the magnets and the remainder passing on. As the "slip" has to pass over a series of small falls in cascade fashion, any pieces of metal are certain to be extracted. (Prior to this process the various ingredients have been weighed and mixed in an agitator known as a "blunger.")

The "slip" is, of course, too thin in consistency for moulding into ware, and must be made into a firm and plastic condition. This is done in a filter press, an appliance used in many trades. Briefly, this consists of a number of cloth bags in square frames, which are screwed together horizontally, the whole resembling a

FROM BINN, "POTTERS' CRAFT" (VAN NOSTRAND)

PROGRESS OF A BALL OF CLAY ON THE POTTER'S WHEEL

be crudely designed and arranged. The cheaper types of china are made in the Nagoya district, but the Imari porcelain (a high-class product) is produced at Arita.

Toy tea sets and dolls are important items in the Japanese porcelain trade, and the annual production of these wares has an average value of £130,000. Porcelain insulators are also exported in large quantities, and many users of wireless materials will probably have handled this particular ware.

Japan imports considerable quantities of raw materials, but maintains an export trade in spite of this handicap. Cheap labour

"square" loaf, cut into slices, but retaining the shape of the loaf. By pressure, the surplus water is removed and the clay, now in flat slabs, is rolled up and passed on to the "pug mill." This piece of machinery may be likened to the domestic mincer or meat grinder. Blades, revolving in a manner popularly known as the "spiral," knead the clay and force it through a circular opening, from which it emerges as a huge "sausage."

In the pottery industry, as in all other artistic crafts, mechanical means cannot effectively replace the dexterity of man or woman. The "pug mill," *e.g.*, is an admirable method for kneading the clay, but it cannot do it so effectively as an experienced pottery worker. Such a man would cut a lump of clay into two pieces and bang one on to the other, a process which he repeats many times. Obviously this is a slower and more expensive method, and cannot be used for the cheaper types of ware.

Throwing.—The clay is now ready for making into the ware. Everyone has heard of the potter's wheel, but many have probably not seen one or have an incorrect impression of this simple appliance, which plays such an important part in the making of some delightful pieces of pottery. It is not a wheel, as generally understood, but a circular, horizontal disc, which revolves at the will of the thrower. A ball of clay is thrown on to the "wheel," and then the "thrower," after getting it into the condition of plasticity he considers most correct, deftly transforms the ball of clay into whatever shape he is proposing to make, by pressing it with his fingers as the "wheel" revolves. In this way a symmetrical form is obtained. The art of the potter is infinite, and it is little wonder that his skill in transforming an ugly ball of clay into a bowl or vase of beautiful contour has moved poets to acclaim his craft.

For domestic articles, such as cups, the thrower may be aided by a mould, which is made of plaster of paris. The inside of the mould will correspond to the shape of the outside of the cup. It is a simple matter—to the experienced thrower—to press the clay into the mould until the desired thickness is obtained. The plaster of paris absorbs some of the moisture in the clay, which, besides contracting, becomes correspondingly harder, and therefore much more easily handled by the potter. The cup is then passed on to a man who turns (or trims) it on a lathe. The cup, of course, is not complete without a handle, which could not be thrown on the wheel. It is therefore "cast," the clay taking the shape of a plaster of paris mould. After trimming, the handle is affixed to the cup by dipping the ends in some "slip." When joining together two pieces of clay, it is important to ensure, as far as possible, that the percentage of moisture is approximately the same in each, for if one is drier than the other, unequal contraction will take place, with the result that the two will part company. This is one of the many contingencies that the potter has to guard against, and it will readily be seen that a large amount of skill and experience is necessary for the production of good pottery.

Turning.—This important operation in the manufacture of pottery has been mentioned above. It will be obvious that the products from the thrower's hands will need trimming if a smooth finish is required. Some potters, particularly those known as "artist potters," who, however, usually work with coarser "bodies" (heavier types of clay), like to leave the marks of the thrower's hands, just as some take a pride in the hammer marks on hand-wrought silver ware. In commercial production, particularly if moulds are used, as mentioned in the previous paragraph, a little trimming is necessary. When the ware is moulded, a process that will be described later, turning will be an essential operation.

It must be remembered that the clay, when it reaches the lathe, is becoming harder; at this stage it is known as "green hard," a condition which has been likened to hard cheese, while another description is "leather hard." In such a condition the cup or other article can be shaved or trimmed on a lathe just as a piece of wood can. Any unevenness can be removed, while, if a "foot" for the ware is required, this can be formed by the turner. An additional advantage of the lathe is the speed with which the ware may be "embossed" with decorations, such as beads, etc. While the ware revolves, the turner presses against it a little wheel, which has the decoration engraved upon it, in reverse.

The lathe used for this work resembles in many respects the machine used for wood or metal turning. The principal difference is the method of holding the article to be turned. In the pottery industry, the ware is placed in a "chum," a hollow drum that grips the piece at about half its length. When the exposed half has been finished, the ware is reversed and the process continued.

In the case of cups, and other ware requiring handles, it will be obvious that the turning must be done before the handle is applied.

Jolleying.—Although the methods of the early potter have remained almost unaltered in many respects, the large output of the modern factories makes it necessary to provide a means whereby a more rapid production of ware can be maintained. The "jolley" takes the place, to some extent, of the thrower; but man's skill is still needed to ensure the output of good pottery. Again, we have a small revolving disk, and on this a mould of the exterior of the article to be made is placed. Into this a slab or "bat" of clay is thrown. The mould forms one side of the piece of ware (the exterior), and the interior is shaped by a "profile" which is brought down by a lever and cuts away the clay to the desired thickness, the mould on the platform being revolved during the process.

For flat ware, such as plates and saucers, the procedure is slightly different. Such pieces are made upside down, the bottom of the plate, or saucer, being uppermost. The mould in this case will furnish the shape of the interior or top of the ware, while the profile, which is lowered on to the revolving slab of clay by the lever, will form the underside.

When the piece of ware has been fashioned on this machine, it is taken, still on the mould, to a drying chamber. Here the clay contracts and the saucer, or whatever it may be, is lifted away and passed on for finishing. This means the trimming of the edges, and smoothing with a flannel and fine sandpaper. It should be a cup, a handle has, of course, to be applied.

Pressing.—This process consists of placing soft clay, which has been beaten out to the required thickness, into plaster of paris moulds, which may form one half of the ware. When the halves have been made they are brought together to form the whole, the joints being finished off. After sufficient water has evaporated, the ware can be removed, and handles, knobs, feet, or any other parts which have been fashioned in a like manner, are then attached.

Casting.—Many will have a passing acquaintance with this process, for the method of casting metals is well known; in the pottery industry the "slip" takes the place of the molten metal. The "slip" is poured into plaster of paris moulds, which absorb some of the moisture, leaving a layer of clay. When the clay is of sufficient thickness, the surplus "slip" is poured away, and the mould, with its clay lining, is taken to the drying room, where the ware contracts and hardens, making it suitable for removing and finishing off as in the case of pressed ware. The moulds may form only part of the finished article, the remainder being made in other moulds. When ready, the pieces from each mould are joined together. It will be seen that casting is similar to pressing, except that the potter is able to commence with an easily handled material (the "slip") which, owing to its limpidness or low viscosity, rapidly takes the shape of the mould. The process is therefore simpler and, consequently, cheaper. It is a method which lends itself admirably to the reproduction of figures and other modelled ware.

Mould-Making.—Plaster of paris moulds have been frequently mentioned in the various processes already described, and it will be useful to interpose here a brief description of the making of these moulds, as, undoubtedly, it is an important feature in modern pottery manufacture.

Plaster of paris is made from gypsum, a naturally occurring mineral composed of calcium sulphate. Gypsum is hydrated, *i.e.*, it contains a certain amount of combined water, which can be driven off by heat. When it has been calcined an amorphous powder is left, known as partially hydrated calcium sulphate, or plaster of paris.

This material has a peculiar property in that it swells when water is added, forming an absorbent solid, which lends itself

STAGES IN THE MANUFACTURE OF POTTERY AND CHINAWARE

1. An artist-potter transforming a lump of clay into a piece of pottery on the potter's wheel. The potter presses the soft clay into shape while the wheel revolves
2. Showing the "thrower" in a factory pressing a cup into shape in a plaster-of-Paris mould, a process that requires considerable skill. The handle of the cup is made separately and put on afterwards
3. Fashioning a saucer in the "jolly." Clay has been thrown on the mould, which is on a revolving platform, and the operator is bringing down a lever to which is attached a tool which shapes the underside of the saucer
4. A workman showing a plaster-of-Paris mould for a saucer into which is poured the "slip," a thin mixture of clay and other ingredients with water. When the mixture is solid the saucer is ready for lathe finishing and firing in the kiln
5. Trimming the "foot" of a plate on a lathe, which smooths off all uneven surfaces. By pressing a die against the ware as it revolves, it is possible by the same process to apply a raised decoration
6. Dipping cups and saucers into tubs of glaze, a process to which all china for domestic purposes is subjected. This glaze after firing in a kiln makes an extremely hard and durable finish

FIRING AND DECORATING CHINAWARE

1. A "sagger" in which glazed ware is being arranged for firing. the pieces are packed separately, extreme care being taken that no mark is left on the glaze. The article must touch the supports at the bottom, and it is sometimes possible to see these marks on the finished pottery
2. Oven in which the ware is fired. "Placers" are putting the saggars in place. When the oven is full the opening is closed and sealed and the fire is lighted
3. Decorating cheaper types of ware by means of transfer. Conventional designs are printed on sheets of paper, which are cut into strips. These are pressed on to the cups. When the paper is removed the design remains and is hardened in a kiln
4. Painting designs on pottery. Often, the outline is first printed on the ware and the colour filled in by the artist. Colours used must be able to withstand the high temperature required for firing
5. Decorating ware with clay decorations. The ornamentations are first fashioned in moulds and then pressed on the ware. This process is known as *pate-sur-pate*

readily to the formation of various shapes by carving, turning on the lathe, etc. Every cup, jug, or other piece of ware produced, must, of course, have had an original from which it is duplicated. The original is modelled in clay and is solid, *i.e.*, it gives the shape of the *exterior* only. From this model the plaster of Paris mould is prepared. This is a process that needs special care, for upon the mould the accuracy of all the reproductions depends. The mould may be in three parts, two halves, forming the sides, and a bottom. From this mould a duplicate of the original can be produced, and, in turn, moulds for reproductions. The number of pieces of a mould will depend upon the shape of the article to be made.

Modelling.—As stated above, every piece of ware produced must have had an original, which may vary from an ordinary teapot to a dainty shepherdess, or a group of several figures. The modeller's skill in this matter may be likened to that of the artist who paints a picture for reproduction. The modeller creates and the craftsman copies.

But the task is not ended when the modeller has finished his work; considerable skill is required to reproduce his work faithfully. When the modeller's work takes the shape of a figure in fanciful pose, many moulds have to be made, and the number may be as high as 28. Arms, legs, hands, head and many other parts have to be moulded separately and then joined to make the figure created by the modeller. As the pieces are often hollow, it will readily be seen that great care must be exercised by the man whose occupation it is to assemble the various parts, as undue pressure on the pieces would cause distortion and the spirit of the modeller's art would be lost.

A further difficulty, which affects the modeller, is that allowance must be made for contraction. The mould from his model will, of course, give a piece of ware corresponding, in its raw state, to the original; but when the reproduction has lost its moisture and has been further contracted by the firing, the figure (or whatever it may be) will be much smaller. This shrinkage may be as much as one-tenth. Obviously the modeller must keep this in mind when at work on an original.

Firing.—The processes described have led up to the first firing of the ware, when what is known as "biscuit" is produced.

The shape of a pottery oven, or kiln, will be familiar, by photographs and drawings, to many. The huge, bottle-shaped ovens are peculiar to the pottery industry. They are heated by fires placed at intervals at the base. Coal is the fuel principally employed, but electrically heated ovens have made an appearance, while oil and gas have their advocates. On the Continent and in the Far East wood often plays an important part in the firing.

As thousands of pieces of ware may be fired at one time, the arrangement in the oven needs special care. It would not, of course, be possible just to stack clay cups on top of one another; even if they kept in position, the weight on those below would, at least, cause distortion. The ware is therefore placed in "saggars," which are largely fireclay receptacles resembling big cheeses in shape. In these the "green" ware is placed, separated by ground flint, which, owing to its very high melting, or fusing point, will not affect the ware in the oven. The "saggars," when filled, are "placed" in the ovens, special care being taken to see that they are perfectly level. As a rule, hollow ware (such as cups) is placed at the top of the oven and flat ware (such as plates) at the bottom. When filled, the ovens are sealed up and the heating is commenced, continuing for about 50 to 60 hours. For the first 24 hours the firing is slow, *i.e.*, the temperature is not raised unduly, to drive out the moisture. The temperature will then be increased until it reaches about 1,300° C. A necessary precaution is to ensure that the temperature never falls back. This is part of the fireman's responsibility; he must also know when the firing is complete. He has means of testing the rate of progress of the firing, but the control of the temperature and the length of time given needs skilful judgment. Very useful pyrosopes for determining the proper heat treatment attained in an oven are employed frequently. Some are small tetrahedra, called cones, compounded from a series of ceramic mixtures. These cones are placed in the oven where they may be observed by the fireman. As a certain temperature is reached, depending somewhat on the

rate of temperature increase, they bend so that the apex gradually touches the base. The finishing point of the firing may thus be indicated. These pyrosopes are called Seger cones after their inventor. Other temperature indicators are Holdcroft's thermosopes. These are small bars supported at their ends in a horizontal position. When the critical temperature of a bar is reached it sags in the middle. The Seger cones and Holdcroft's thermosopes are given a variety of numbers, the refractoriness of the cone or bar increasing as the numbers go up. Pyrometers, scientific instruments for measuring heat, may be employed instead of the pyrosopes. When the firing is complete the oven is allowed to cool; this takes about the same time as the firing—50 to 60 hours.

The biscuit ware, when it leaves the oven, must be translucent, and it is the aim of all the makers to obtain a ware with a perfect translucent body, free from blemishes.

Glazing.—When the "biscuit" ware was produced by the first firing has been sorted (for the rejection of any pieces containing flaws), and cleaned, it is ready for the "dipper," the man who dips the piece into a tub of glaze. The glaze is made from a variety of ingredients which, when fused, form what might be termed "glass," for the glaze on a piece of china is really a glass. Lead is an important ingredient in many glazes and the question of lead poisoning has long been a problem in the pottery industry; but this is being overcome by the introduction of low-solubility glazes.

It may appear a simple matter to dip a cup into a tub of glaze, but here, as in most of the processes through which the ware has to pass, the skill of the worker is all important.

The ware, with its coating of glaze, has now to be fired again, when the opaque covering will be rendered translucent. The china is arranged in saggars, the round, cheese-shaped, fireclay receptacles already mentioned, but this time the sagger will be glazed inside, otherwise trouble would arise owing to absorption. The saggars are "placed" or stacked in the oven. This oven is known as the "glost" oven, and the man who stacks the saggars containing the glazed ware is called a "glost placer." Before the ware reaches the "glost placer" it passes through a drying room and is cleaned. Where there are small holes in the ware, in pepper pots, for instance, any glaze filling the openings must be entirely removed.

The saggars are arranged in the oven, as in the case of biscuit ware, but this time rolls of fireclay are placed between the saggars. This clay, by the pressure of the sagger above, effectively prevents any products of combustion from reaching the glaze, which, obviously, would be spoiled.

Decorating.—In the early days of pottery making, decoration was not as we understand it to-day—it was confined more to shapes than applied colours. Those who are familiar with the Greek urns will readily appreciate the beauty of the outlines; but in the 20th century pottery is judged more by the decorative scheme. Our modern potters do, of course, pay considerable attention to shapes; but the general public, with an appetite for colour, looks for applied decoration.

The limitations, and the great skill required by the pottery artist, are little known to the average purchaser in a retail establishment. Unlike most other decorative processes, the colours, especially if under the glaze, have to be subjected to a very high temperature for the glaze itself demands this, and therefore many pigments are unsuitable, as they would be destroyed by the heat. Metallic oxides are used, such as cobalt oxide for blue, uranium oxide for yellow, chromium oxide for green, iron oxides for reds and reddish browns.

Underglaze decoration is particularly suitable for household ware, as it is indestructible, and cannot be worn off in use. On the commoner types of domestic china the design would probably be "printed," a process which is carried out as follows. A copper plate is engraved with the design, which is filled with colour mixed with oil. The printer cleans off any surplus colour and then applies a sheet of tissue paper (which has been water sized) to the plate. The copper plate, with the paper above, is then passed through a roller press, which causes the decoration to adhere to the paper. The tissue is now pressed on to the ware, and on its removal, by

UNITED STATES CHINAWARE

soaking in water, the decoration remains behind. The design will probably be in outline and this may be filled in by hand, an operation cleverly carried out by girls. When the decoration is complete the next step is to remove the oil, for this would interfere with the application of the glaze. To do this the ware is placed in a kiln, where it is fired at a low temperature, though a sufficiently high one to destroy the oil and leave the colour "fixed." The china is now ready for the glaze, and is finished as already described. Hand-painted work can also be done under the glaze—with a limited palette.

For overglaze decoration a much wider range of colours is possible. A flux is added so that the resulting colours are really glasses, although enamels, as they are called in the industry, is a better term, which will be readily understood if one thinks of the enamelled ware in jewellers' shops—not the air-dried enamel used by house decorators.

Many pieces of domestic ware have a gold band or a gold treatment somewhere in the decoration. This is applied in two forms: "best" gold and "liquid" gold, which is an alloy. The "best" gold comes out of the kiln in a dull condition, but can be burnished to a bright tone. The "liquid" is bright when it leaves the kiln, but it has not the beauty or the wearing qualities of the other. There is a type of decoration known as "acid gold." A design is etched on to the glaze with hydrofluoric acid, which eats away the glaze unprotected by a "resist." The etched part may be coated with "best" gold, which, after being fired, is burnished, with the result that the gold in the depressions formed by the etching remains dull, while the burnished part is bright.

The decoration particularly suitable for rapid production is that of lithography. Lithographed designs are quite common for the cheaper classes of ware, and, while they may not always appeal to the critical eye, nevertheless satisfy a large percentage of the population.

The design is made up on several stones, one for each colour. These colours are transferred to sheets of paper, so that the complete decoration is obtained on one sheet. We have now what is commonly termed a "transfer." This is applied to the ware, the design remaining after the removal of the paper. The colours are fired in the enamel kiln.

A type of decoration that has not been employed to any great extent since the 19th century is that obtained by building up flowers, in clay, petal by petal, on the ware. This calls for exceptional skill on the part of the artist.

Very fine effects are obtained with a process of decoration known as "pâte-sur-pâte." Commercially various designs are modelled in white clay and affixed to the ware.

THE USES OF CHINA

Owing to its acid and heat resisting properties china finds a special use in chemical industries. It will often be found in large industrial concerns where cleanliness is of great importance. It is even employed in grinding—porcelain balls pound materials in a cylindrical machine known as a "ball mill." Porcelain is also used for the linings of these mills.

It is a splendid material for insulating, and consequently is much used by the electrical industry. In Central Europe the bowls of tobacco pipes are composed of porcelain.

Its use in domestic ware is well known, while almost everyone possesses a dainty figure or some other piece of ornamental porcelain. (See also POTTERIES and PORCELAINS, EARTHENWARE.)

See Emile Bourry, *A Treatise on Ceramic Industries* (trans. from the French with some additional notes by Alfred B. Searle), giving a complete description of pottery processes; *The Manual of Practical Potting* (ed. Charles F. Binns); Rudolf Hainbach, *Pottery Decorating* (English trans. published); William Burton, *Porcelain*, describing the nature, art and manufacture of porcelain; A. Malinovsky, *Ceramics*, a book for chemists and engineers in the pottery industry; C. F. Binns, *The Potter's Craft*, for the studio potters, schools, etc.; Chas. J. Noke and H. J. Plant, *Pottery*, a small popular book by two men well known in the pottery industry; *A Text Book for Salespeople engaged in the Retail Section of the Pottery and Glass Trades*, written by an expert committee in conjunction with the Education Committee of the Pottery and Glass Trades' Benevolent Institution for the guidance of students.

(G. C.)

Earthenware.—The tableware made in the United States represents to a very large extent a high grade of white earthenware, also called semi-vitreous or white ware. This product is made in 60 potteries and its composition is approximately as follows: English ball clay 13%, feldspar 13, English china clay 25, North Carolina kaolin 10, Florida kaolin 6, flint 33. However, the use of American clays is steadily replacing the imported materials. The biscuit firing is done at about 2,200° F, pyrometric cone 8, the glost firing at 2,150°, cone 5, and the decorating firing at 1,350°, cone 017. The glaze is invariably a boro-silicate of the alkalies, lime, lead and zinc. The operations are practically the same which prevail in Staffordshire (England) except that both the bisque and the glost firing are carried to a higher temperature. The use of tunnel kilns for all three firings has become very extensive. Ivory coloured ware is produced in large quantities and this colour is obtained through the use of larger amounts of American ball clay and the introduction of yellowish firing kaolins. The tendency towards the application of vivid over-glaze colours is very marked at the present time. Practically no under-glaze decoration is applied. The principal centre of the white earthenware industry is East Liverpool, O., including potteries located just across the Ohio river, at Newell and Chester, W. Va. Within a short distance of East Liverpool factories are operating at Sebring, East Palestine, Salineville, Minerva and Carrollton, O. Formerly, a considerable quantity of white ware was produced at Trenton, N.J. But this activity has diminished to comparatively small operations.

Vitreous Ware.—The demand for non-absorbent, vitreous table ware for hotels and restaurants has stimulated the American potters to develop such a product quite obviously from the semi-vitreous type of body through the increase in fluxing material and the raising of the bisque firing temperature. Thus, the composition of a vitreous body would be as follows: Feldspar 15%, flint 38, ball clay 6, china clay or kaolin 40, whiting 1. The biscuit firing is carried to cone 11, or about 2,300° F. The resulting product shows the "stony" type of vitrification as distinguished from the "glassy" structure, possesses great toughness and mechanical strength and is translucent but markedly less so than the hard fire porcelains of continental Europe and bone china. The processes are essentially the same as practised in the earthenware manufacture except that, previous to the biscuit firing, the green flat ware is sanded, in which operation sand is shaken between the individual plates of a bung. The glaze is practically the same as that of earthenware though it is fired to a somewhat higher temperature. Under-glaze decoration is used to a large extent though largely confined to lines and plain printing. However, increased application is being made of polychrome lithographic transfer, decalcomania, as the development of the industry extends to the production of household china. Over-glaze decoration is also applied. The vitreous tableware industry is scattered and factories are located at Trenton, N.J., Syracuse, N.Y., Beaver Falls, Pa., New Castle, Pa., Wheeling and Clarksburg, W.Va., and Wellsville, O.

Belleek China.—There is produced in the United States a highly decorated grade of china, known as the Belleek type, which is named after a similar porcelain produced in Ireland. This product has attained an international reputation under the name of Lenox china. The porcelain is highly translucent, of an ivory colour and has a texture well suited for ornate decoration. The main flux of the body is a pre-fused, glassy mass, composed of feldspar, flint and alkalies. The body thus consists of this flux, feldspar, china and ball clay. The biscuit firing temperature is considerably below the maturing point of the other types of porcelain. The glaze is a very brilliant boro-silicate of the alkalies, lime, lead and zinc. The principal production of this type of china is at Trenton, N.J.

Hard Fire China.—Hard fire china, similar to the porcelains of Austria, Czechoslovakia, France and Germany, with a low temperature biscuit and high glost fire, is produced only by three factories and on a comparatively small scale. The body employed is somewhat more silicious than the typical European product,

which has approximately the composition: Kaolin, 50%, feldspar, 25% and flint, 25%. The glaze firing temperature is somewhat lower than that of European practice, being close to 2,410° F, or cone 12. There are indications that a considerable expansion in the production of hard fire porcelain is to be looked for in the near future. Laboratory and technical porcelain is being produced by two factories.

The subject of high fire porcelain cannot be dismissed without referring to an American development which works with exceedingly high temperatures. Through the introduction of synthetic mixtures or of natural minerals of the sillimanite group which have the general composition, $Al_2O_3SiO_2$, aluminous porcelains are produced which show remarkable mechanical strength and resistance to thermal shock. These properties are associated with the extensive development within the fired body, of a crystalline compound, mullite, which has the composition, $3Al_2O_3 \cdot 2SiO_2$. This compound is formed in all porcelains but in these special bodies, through the deliberate exclusion of nearly all crystalline silica and its replacement by the aluminum silicate just referred to, a very large proportion of the mass consists of mullite. The porcelains are fired at temperatures between 2,650–3,000° F, cones 17 to 30. The dense crystalline structure and the low thermal expansion are responsible for the high mechanical strength and resistance to thermal shock. This type of porcelain is marketed in the form of insulators for spark plugs and other electrical purposes, laboratory and technical ware, special refractories, etc. Products of this kind have become known on the market as sillimanite porcelain.

Bone china, as made in England, is produced in the United States only in relatively small quantities, owing to the lack of the specially skilled and trained workers required in its manufacture. (A. V. B.)

CHINCHA ISLANDS, three small islands in the Pacific Ocean, about 12m. from the coast of Peru, to which country they belong, opposite the town of Pisco, and 106m. from Callao, 13° 38' S., 76° 28' W. The largest of the group, known as the North Island or Isla del Norte, is only four-fifths of a mile in length, and about a third in breadth. They are of granitic formation and rise from the sea in precipitous cliffs, worn into countless caves and hollows, which furnish convenient resting-places for the sea-fowl. Their highest points attain an elevation of 113ft. The islands have yielded a few remains of the Chincha Indian race. They were formerly noted for vast deposits of guano, and its export was begun by the Peruvian government in 1840. The supply, however, was exhausted in 1874. In 1853–54 the Chincha islands were the chief object in a contest known as the Guano war between President Echenique and General Castilla; and in April 1864 they were seized by the Spanish rear admiral, Pinzon, in order the Peruvian government to apologize for its treatment of Spanish immigrants.

CHINCH BUG, a North American heteropterous insect (*Blissus leucopterus*) occurring in most parts of the United States, but particularly destructive to grain crops in the valleys of the Mississippi, Missouri and Ohio rivers. It is probably the most destructive native insect, and has frequently damaged crops to the extent of many million dollars in a single year. It was first noticed in North Carolina, at the close of the Revolutionary War, was first described and named by Thomas Say in 1831, and with the growth of agriculture in the Middle West, soon became a pest of the first importance. In 1871 it damaged the wheat, oat and barley crops of Illinois, Iowa, Indiana, Nebraska, Missouri and Kansas to the estimated amount of \$30,000,000. The loss in 1887 to maize, wheat and oats was estimated at \$79,000,000.

Originally the chinch bug fed upon wild grasses, but when the cultivation of wheat reached its native haunts it multiplied enormously. It is a small black and white insect, about $\frac{1}{2}$ in. long, and when full grown has a long-winged and a short-winged form. The adult bugs hibernate in sheltered places, usually clustering about the roots and bases of grassy plants. In the spring they lay their eggs behind the lower blades of the grain or in the ground around the plants. The young, when hatched, are bright red in colour, and begin at once to suck the sap of the plants.

They grow rather rapidly and shed their skins five times, the adult being the fifth stage. By the time the majority are full grown, or even before, the wheat has become too hard to suck, or harvest begins, and they are then compelled to migrate in search of food.

The cropping systems prevalent in the Middle West offer at once new sources of food. In seasons of abundance the bugs march in throngs from the wheat to the maize. The full-grown individuals do not generally take wing, but walk along the ground. Occasionally, however, at this time they take wing and scatter. There is generally a second generation on maize, the adults appearing in the autumn and flying back to their winter quarters at the roots of wild grasses or other sheltered places.

The chinch bug is most susceptible to weather conditions, and with wet weather in the late spring and toward the end of July the young are either destroyed by the water or develop an epidemic fungous disease. In dry weather, however, they flourish. Seasons in which they occur in great numbers are rarely consecutive. Outbreaks have lasted for two or three years, but, in the same locality, years of abundance are apt to be separated. Serious damage may be obviated by proper cropping of farms, reducing the acreage of small grains and using the land for immune crops. Resistant varieties of grains have also been found. At the time of migration, millions may be destroyed by barriers of various kinds, including ditches, and by using kerosene or creosote. Taking advantage of the hibernating habit, the burning of old grasses, particularly the so-called bunch-grass along roadsides, when organized and done co-operatively, destroys the bugs wholesale and often has the good effect of preventing serious losses during the following summer. Calcium cyanide in dust form has also been sometimes used. But community burning of winter grass seems to be, on the whole, the most feasible means of control. (L. O. H.)

CHINCHILLA, a small grey hopping rodent (*Chinchilla lanigera*), the size of a squirrel, inhabiting the eastern slopes of the Andes in Chile and Bolivia, at altitudes between 8,000 and 12,000 ft. It typifies not only the genus *Chinchilla*, but the family *Chinchillidae* (see RODENTIA). The chinchilla is about 10 in. in length, exclusive of the long tail, and in the form of its head somewhat resembles a rabbit. It is covered with a dense soft fur of a delicate French grey, darkly mottled on the upper surface and dusky white beneath, the ears being long, broad and thinly covered with hair. Chinchillas live in burrows. They associate in communities, forming their burrows among loose rocks, and coming out to feed in the early morning and towards sunset. They feed on roots and grasses, and when eating they sit on their haunches, holding their food in their fore-paws. The fur (*q.v.*) of this rodent was prized by the ancient Peruvians, and at the present

BY COURTESY OF AMERICAN MUSEUM OF NATURAL HISTORY

THE CHINCHILLA, A NATIVE OF SOUTH AMERICA, ALTHOUGH ITS NUMBERS ARE DECREASING, IT IS OF COMMERCIAL IMPORTANCE FOR ITS SOFT, LUSTROUS GREY FUR

day the skins are exported in numbers to the markets, where they are made into muffs, tip-pets and trimmings. That chinchillas have not under such circumstances become extinct is owing to their fecundity, the female producing five or six young twice a year. The Peruvian chinchilla (*C. brevicaudata*) is larger, with relatively shorter ears and tail; while still larger species constitute the genus *Lagidium*, ranging from the Andes to Patagonia, and distinguished by having four in place of five front-toes, more pointed ears, and a somewhat different skull. (See also VISCACHEA.)

CHINDE, a town (municipality) of Portuguese East Africa, and seat of local Government representative (Intendente), is the chief port for the Zambezi valley and the centre of distribution of the river traffic for the interior as far as Tete. Till recently it was also the chief port for British Central Africa. It is situated at the mouth of the Chinde branch of the Zambezi, in 18° 40' S., 36° 30' E., 62 miles from Quelimane, 146 from Beira, and 969

from Durban. Pop. (1927), 133 Europeans, 71 Asiatics and 1,266 natives. Large steamers are unable to cross the bar, over which the depth of water varies from 10 to 18 ft. Chinde owes its existence to the discovery in 1889 that the branch of the Zambezi (*q.v.*) on the banks of which it is built is navigable from the ocean. By the Convention of 1891, an area of 5 ac.—subsequently increased to 25—was leased for 99 years to the British Government, on which goods in transit to British possessions can be stored duty free. This area, known as the British Concession, is also in part used for residences and for business establishments. There is a slip for the sternwheel river steamers, which connect with the steamers visiting the port, and ply up and down the river to Chindio, Tete, etc. Passengers and goods are sometimes transhipped at Beira for Chinde. At high water the port has a depth of 18 to 19 ft. The climate is not considered unhealthy, but the surroundings are flat, and there are mangrove swamps on both sides of the river. There are two public gardens, and a Decauville line runs to a fine beach where there is good bathing. There is a considerable export trade from Portuguese territory, sugar, cotton and ground-nuts being largely cultivated in the Zambezi valley and gold and copper mines worked. In 1925-26, 91 ships entered and 92 left Chinde, imports were 14,453 tons and exports 22,982 tons, the port had 7.5% of the trade of the province. See PORTUGUESE EAST AFRICA.

CHINDWIN, river of Burma, the largest tributary of the Irrawaddy, called Ningthi by the Manipuris. It is formed by the junction of the Tanai, the Tawan and the Tarôn or Turông, but there is doubt as to which is the main stream. The Tanai rises on the Shwedaung-gyi peak of the Kumôn range, 12 m. N. of Mogaung, and flows due north until it reaches the Hukawng valley, when it turns to the west and meets the Tarôn or Turông river. The last-named flows into the Hukawng valley from the north. Its sources are in the hills to the south of Sadiya, rising from 10,000 to 11,000 ft. above sea-level. It flows in a general east to west direction as far as its junction with the Loglai. It then turns south and breaks into the Hukawng valley a few miles north of Saraw and meets the Tanai about 10 m. above Kintaw village. Below the Hukawng valley the Chindwin is interrupted at several places by falls or transverse reefs. At Haksa goods have to be transhipped from large boats to canoes. Not far below this the Uyu river comes in on the left bank at Homalin, and from this point downwards steamers ply for the greater part of the year. The Uyu flows through a well-cultivated valley, and during the rainy season it is navigable for a distance of 150 m. from its mouth by steamers of light draught. Below Kindat, the only considerable affluent of the Chindwin is the Myit-tha, which drains the Chin hills. The Chindwin rises considerably during the rains, but in March and April is so shallow in places that navigation is difficult even for small steam launches. Whirlpools, narrows and sandbanks also cause great trouble. The extreme outlets of the river are 22 m. apart, the interval forming a succession of long, low, partially populated islands. The most southerly mouth of the Chindwin is, according to tradition, an artificial channel, cut by one of the kings of Pagān. It was choked up for many centuries, until in 1824 it was opened out by an exceptional flood.

CHINDWIN, UPPER and LOWER, two districts in the north-west border division of Burma. Upper Chindwin has an area of 16,037 square miles. Pop. (1921), 186,881. Lower Chindwin has an area of 3,480 square miles. Pop. 342,880. For further details see BURMA.

CHINESE ARCHITECTURE. The art of building in China has always been closely dependent on the intimate feeling of the Chinese people for the significance and beauty of nature. They arranged their buildings with special regard to the "spirits of earth, water and air," their ambition being not to dominate nature by their creations, as Westerners mostly do, but to co-operate with it, so as to reach a perfect harmony or order of the same kind as that which is reflected in the creations of nature. It was less the outward forms that interested them than the inner meaning, the underlying creative forces. This is most evident in the arrangement of some of the great tombs and shrines or in open-air altars

dedicated to the divinities of heaven and earth. But it is also reflected in profane buildings such as the imperial palaces, which were planned and built according to sidereal or cosmological considerations. This appears even from the name used for the present and some earlier imperial palaces: Tzu Chin Ch'eng, the so-called Purple (or Violet) Forbidden City, of astronomical origin: the Heavenly Lord or Ruler Above was supposed to occupy a circum-

polar constellation composed of 15 stars called the Purple Protected Enclosure, and as this was situated in the centre of the celestial world, so was the palace of the emperor, the human representative of the highest divine principle, supposed to be in the middle of the human world.

The general arrangement and planning of the Chinese buildings have indeed very little in common with such artistic points of view as have been applied in Western architecture; they result rather from religious and philosophical ideas which have their roots in most ancient traditions. This accounts also for the uniformity, not to say monotony, of early Chinese architecture. The principles of construction have remained the same during many centuries, as have also the plans of the temples and palaces. The modifications of style which have been introduced are of comparatively small importance. It thus becomes possible to draw some conclusions from relatively late examples about the earlier buildings, which

CHINESE TEMPLE PLAN
Showing the usual arrangement of placing the main buildings in a row, the one behind the other

unfortunately are practically all destroyed; the wooden material has poorly withstood the ravages of fire and warfare, and the people have never made any serious efforts to protect their old buildings. It was mainly for the dead that the Chinese created more permanent abodes, and thus the tombs are the most ancient architectural monuments still existing in China. Besides these there are some cave temples hollowed out in the mountain sides and a few stone and brick pagodas of early date which will be mentioned later.

The Walls of China.—The earliest architectural monument above the soil in China is the "Great Wall," a massive fortification running along the northern and north-western frontier of the country. It was erected by the great Emperor Ch'in Shih Huang Ti shortly after he had reunited the different parts of the country into an empire (228 B.C.). No doubt minor parts of such a wall had existed before his time, but he planned his defence against the nomadic tribes on a very much larger scale than had any previous ruler. It is stated that nearly 750 km. of the wall were built during his reign. Whatever truth this statement may contain, the fact remains that he laid the foundation of one of the world's grandest constructions, which, after many enlargements and restorations in the course of time, is still of great importance. The structural character of the wall is quite simple. It is built mainly of earth and stone, varies in height between 6 and 10 metres and is mostly covered by a coating of bricks. On the ridge of the wall runs a passage three or four metres wide between crenellated parapets, and at regular intervals square watchtowers rise above the ridge on which fires were lighted as soon as any danger was sighted. In spite of this uniformity, the wall is intimately connected with the landscape, rising in many parts almost like one of nature's own creations, accentuating the sharp ridges of the mountain chains and winding according to the undulations of the ground. It is the greatest and most monumental expression of the absolute faith of the Chinese in walls.

THE GREAT WALL OF CHINA

The Great Wall of China at the Nank'ou pass, Chih-li; 228 B.C. It is 1,400 miles long, with square watch-towers at intervals

TWO CITY WALLS

1. Portion of the city wall of Peking; west side, outer view. It is provided with 44 bastions and coated with bricks. The battlements are beginning to crumble. It had been constantly rebuilt or repaired from the end of the 15th to the middle of the 19th century. Its two gates are the Hsi Chih men (north) and Ping Tzu men (south), connecting city and suburbs
2. Portion of the city wall and the double bastion at south gate in Si-an, Shen-si, built at the end of the 14th century, and repaired in places. It encloses an almost square city, and has double gate-towers, square bastions and round corner-towers

Walls, walls and yet again walls, form the framework of every Chinese city. They surround it, they divide it into lots and compounds, they mark more than any other structures the basic features of the Chinese communities. There is no real city in China without a surrounding wall, a condition which indeed is expressed by the fact that the Chinese used the same word *ch'eng* for a city and a city wall; there is no such thing as a city without a wall. It is just as inconceivable as a house without a roof. These walls belong not only to the provincial capitals or other large cities but to every community, even to small towns and villages. There is hardly a village of any age or size in northern China which has not at least a mud wall or remains of a wall around its huts and stables. No matter how poor and inconspicuous the place, however miserable the mud house, however useless the ruined temples, however dirty and ditch-like the sunken roads, the walls are still there and as a rule kept in better condition than any other building. Many a city in north-western China which has been partly demolished by wars and famine and fire and where no house is left standing and no human being lives, still retains its crenellated walls with their gates and watchtowers. These bare brick walls with bastions and towers, sometimes rising over a moat or again simply from the open level ground where the view of the far distance is unblocked by buildings, often tell more of the ancient greatness of the city than the houses or temples. Even when such city walls are not of a very early date (hardly any walls now standing are older than the Ming dynasty) they are nevertheless ancient-looking with their battered brickwork and broken battlements. Repairs and rebuildings have done little to refashion them or to change their proportions. Before the brick walls there were ramparts round a good many of the cities and towns as still may be seen at some out-of-the-way places; before the towns were built there were villages or camps of mud and straw huts surrounded by fences or ramparts of a temporary character.

Types and Construction of Buildings.—Whether the buildings were imperial tombs, Buddhist temples or memorial shrines dedicated to great philosophers or, on the other hand, of a profane nature, such as imperial palaces, dwelling-houses or administration offices, all were arranged within walls and in closed compounds according to similar principles. Characteristic of all these extensive compounds is the clear development of a main central axis running from north to south. The principal buildings, their courts and gateways are all placed in a row, one behind the other, while the secondary buildings are arranged at the sides of the courtyards, the façades, the doors and the gates of the principal buildings all facing south, an orientation which evidently was based on religious traditions. It was not by adding to the height of the buildings but by joining more courts to the compounds that these architectural compositions could be enlarged. There are princes' palaces in Peking which have as many as 20 courtyards and some of the large temples or monasteries have a still larger number of such units. As each compound is enclosed by a high wall it is quite impossible to obtain any idea of the arrangements from the outside, and at the larger palaces the different courtyards are also divided the one from the other by secondary walls with decorative gateways. The courts vary in size and the streets follow along the walls. Through such an arrangement the inner portions of the Purple Forbidden City of Peking became almost labyrinthine.

thine.

The types of the principal buildings also remain the same, independently of their use as temples, palaces or dwelling-houses. The most common among these types is the hall, *tien*, i.e., an oblong, rectangular room, usually divided by rows of round pillars or columns into three or more naves of which the foremost is usually

WU-LIANG TIEN, SUCHOW, A 2-STOURED HALL WITH BARREL VAULTS

arranged as an open portico; in other cases the open colonnade is continued all around the building. The interior is, as a rule, lighted by small windows placed quite low, but exceptionally there may be a second row of windows, giving a brighter effect; these are at a higher level. Very important for the decorative effect of the buildings is the broad substructure, the terrace and the far projecting roof. When the substructure is made higher, a so-called *t'ai* is created, i.e., a shorter hall or a centralized building in two storeys on a high terrace with battered walls. Such *t'ai* are often mentioned in the old descriptions of palaces and cities. They seem to have been quite common since earliest times. In the Forbidden City of Peking this type of building is beautifully developed at the outer gates as, for instance Wu Men, where the great pavilion rises on a monumental terrace. Other characteristic examples of *t'ai* are the drum and bell towers which rise in the centre of many of the old cities in northern China, but similar buildings have also been used as storehouses, watchtowers and observatories. The general name for larger, many storeyed buildings is *lou*, a name which, however, is not used for the pagodas, whereas small buildings of two or more storeys often are called *ko*, and the open small pavilions *t'ing*. Furthermore, one finds in some of the palatial compounds as well as at many private dwelling-houses, particularly where they are connected with gardens, so-called *lang*, i.e., long open galleries which serve to connect larger buildings.

Considering the most common Chinese buildings such as the *tien*, the *t'ai* and the *t'ing* in their entirety, we may be struck by the fact that the main body of the structures appears much less than in Western buildings. It is, figuratively speaking, pushed into the background by the broad terrace and the far projecting roof which throws a broad shadow over the façade. These two elements are of the greatest importance for the general effect of the structure. The terrace may be developed in various steps and provided with marble balustrades and decorative staircases, as, for instance, at the imperial palace and many large temples, or it may be simply a stone-lined substructure with one or two steps; but it always contributes to lift the building and to form a kind of counterbalance to the projecting roof. It is, however, at the *t'ai* that the substructures become of greatest importance. They may reach a height of 10 or 12 metres and be covered by a hall or pavilion of tower-like effect.

The buildings which rise on the terraces are made of wood; their structural frame is pure carpenters' work. The walls may look massive and appear to support the roof but, practically speaking, they have no structural importance. They are simply filled with brick or clay between the supporting columns. In the larger buildings the outer wall on the façades is usually not placed in the fore-

YÜ HUANG MIAO ON PIAO SHAN
NEAR TSINANFU

most row of columns but this is reserved as an open gallery. In some instances the portico is double, in other cases it is reduced to a few intercolumns in the middle. The building thus consists of a nave and aisles some of which might be completely or partly divided by filled-in walls, by which various rooms are created which indeed may be quite freely increased or decreased, the middle one being, as a rule, the broadest. The intervals between the columns are on the whole quite wide, and sometimes it happens that some columns are excluded in the midst of the building in order to create more free space. But the Chinese hall is not a longitudinal structure like the Greek temples (which also originally were built of wood); it expands transversally to the central axis which is indicated by the entrance door on the middle of the façade. The two short sides with the gables serve

ROOF CONSTRUCTION ACCORDING TO YING TSAO FA SHIH (1103)

no other purpose than to end the hall; they have no decorative importance and no such emphasis as in the classic temples; sometimes they are hardly meant to be seen. The side walls may project as a kind of ante-room to the portico or the corners may be accentuated by columns. The Chinese builders were never so particular or consistent in the placing of the columns as the classical architects. They employed a material which allowed greater freedom than the marble beams and they yielded less to purely artistic considerations than to practical wants. The beauty and strength of their architecture depend mainly on the logical clearness of the constructive framework.

This comparative freedom in the placing of the columns is rendered possible also by the fact that they are not supporting posts as in the classical buildings. They are not provided with capitals and they do not support the entablature, but they are tied both longitudinally and transversally by beams which may cut into, or run through, the posts. The ends of the transverse beams often project in front of the columns, and the longitudinal beams form a kind of architrave which keeps the outer colonnade together. In larger buildings of comparatively late periods brackets or cantilevers are sometimes introduced on the columns below the tie beams but the real bracketing system which serves to support the eaves of the roof is situated above these. The roof brackets are, in their simplest form, two-armed and project in the earlier buildings only from the heads of the columns; but in the later buildings they become manifold and are placed on the beams as well as on the posts, sometimes so close together that they create the impression of a cornice. It is mainly in the modifications of the bracketing system that one may trace an evolution of Chinese architecture.

The constructive system demanded that the buildings should be developed horizontally rather than vertically. Nevertheless, many of the large halls are erected in two storeys, though the second is often nothing more than a decorative superstructure without floor or windows. The lower storey forms a kind of outer compartment to the building and is covered by a lean-to shed roof while the main span or saddle roof covers the central portion of the building which rises to a greater height. Sometimes there is a coffered or painted ceiling over this portion but more often, particularly in the temples, the trusses and beams of the roof construction are left entirely uncovered.

Roofs.—It is evident that the development of the roof on the Chinese buildings is closely connected with the placing of the entrance door. This is not to be found on the short-(gable) ends of the building but in the middle of the southern façade, which usually has also a free-standing row of columns. Most of the important buildings are indeed placed so that they can be appreciated only in full-front view, and their peculiar decorative effect thus becomes dominated by the broad high-towering roof. Whatever the original reason for this particular kind of roof may have been,

it was gradually more and more developed from a decorative point of view. The builders may have felt the need of modifying the impression of weight and breadth, inevitably adhering to the enormous roof masses, and this was most successfully done by curving the sides and accentuating the tension and rhythm of the rising lines. This tendency becomes perhaps more evident in minor decorative buildings such as pavilions and pagodas, not to speak of small ornamental works in clay and metal on which the roof appears almost as a crown. The common dwelling-houses in northern China have, on the contrary, much smaller and less curving roofs and, if we may judge from reproductions of earlier buildings, such as the reliefs from the Han tombs in Shantung and some small clay models dating from the Han and Wei dynasties, it seems that the curved roof was then not very far developed. In the T'ang time (7th to 9th century) the characteristic shape of the roof was, however, fully developed.

It is possible that the origin of the far projecting and strongly curved roof may be looked for in primitive thatch-covered huts of a kind similar to those which still are to be seen on the Indo-Chinese islands. If so, it would first have been introduced in southern China (where indeed the curving and projecting roof always was more strongly developed than in the north), and later on, when the whole country became more of a cultural unit, in the northern provinces. When the Chinese once had realized the fine decorative effect of these roofs, they developed them freely at the expense of the main body of the building. The larger the roofs, the stronger becomes the effect of shade under the eaves and the more they seem to be disengaged from the supporting framework and to soar in the air. In many instances the roofs crown the building rather than cover it, and their decorative ornamentation with figures and animals on the ridges and on the corner ribs serve also to strengthen the impression of a decorative superstructure.

When the building has a roof in two storeys the lower one is a lean-to shed roof; the upper one, a span-roof—but the gables of this do not reach down to the eaves: they are cut at one-half or three-fourths of their height. This peculiar combination of the gabled and the hipped-roof is very common both in China and in Japan, but there are also buildings with complete hip-roofs sloping to all four sides. This is, according to the Chinese, the finest form. It is to be found on ceremonial edifices such as the big central hall Tai Ho Tien in the Forbidden City, Peking, and some of the sacrificial halls at the imperial tombs.

Buildings consisting of two superimposed halls have been in use since very early days, as may be seen on some reliefs of the Han dynasty, and they are also mentioned in many of the old descriptions of the imperial palaces, where such buildings sometimes were connected by flying bridges. Very characteristic and well-developed examples of this type of structure are still to be seen at Yung Ho Kung (the Yellow Temple) in Peking, which was erected in the 17th century as an imperial residence but afterwards consecrated as a Llama temple. Later Lamaistic buildings (from the Ch'ien Lung era) show at times an even further development in height, as for instance the Yu Hua Ko, a temple standing at the north-western corner of the Forbidden City. In southern China the distribution of storeys seems to have been still freer; there are large temples in Suchow with three superimposed halls and other more centralized structures built in the same way, which indeed may be called towers, particularly if they are placed on terraces. The constructive framework of the main roof consists generally of various beams arranged step-wise one above the other and supporting on their ends the purlins (*q.v.*). In smaller buildings all the transverse beams may be supported by columns which increase in length towards the middle of the room, the central one reaching up to the main ridge. It is, however, more common that only the lowest or the two lower beams rest directly on pillars, while the upper ones are carried by brackets and small posts rising from the lower beams. The purlins laid on these supports are arranged rather closely, so that the rafters may be stretched in curves, the projecting ones being spliced and bent upwards. The well-developed system of brackets and cantilevers which support this projecting part of the roof will be specially discussed later because it is in this that one may follow the development and decay of Chinese archi-

ecture.

The outer aspect of the roof is determined by the alternatively convex and concave tiles and the strongly accentuated corner ridges which curve at the ends in a kind of snout and often are provided with series of fantastic human and animal figures, called *k'uei lung tsü*. The main ridge-post is very high and decorated at both ends with a kind of fish-tailed owl, called *ch'ih wen*, which

BRACKETING SYSTEM FROM A PAVILION AT THE CONFUCIUS TEMPLE IN CHÜFÜ. YÜAN PERIOD

had a symbolic significance and served to protect the building against fire and other calamities. On ordinary buildings the roof tiles are of unglazed, lightly baked grey clay, but on the present imperial buildings all the roofs are laid with yellow glazed tiles, while some of the temples and smaller buildings erected for various members of the imperial family have deep-blue roof tiles. Green tiles are sometimes used on pavilions, gates and walls.

The columns as well as the filled-in walls between them have usually a warm vermilion tone which becomes most beautiful when softened by dampness and dust. The beams and the brackets below the eaves are painted with conventionalized flower ornaments in blue and green, sometimes with white contours. The door panels of more important buildings are provided with ornaments in gold, but their upper part serves as windows and is fitted only with open lattice-work. On the whole it seems as if later times had tried to gain by decorative elaboration whatever of constructive significance and beauty had been lost.

Minor Pavilions and Gateways.—Besides the longitudinal halls in right angle to the central axis, indicated by the entrance door, there are more centralized structures on a quadrangular, polygonal or round plan, *i.e.*, pavilions or towers, which may be more than two storeys high. The most primitive type of pavilion is a square hut with corner posts which carry a flat or tent-shaped roof. Such pavilions are often seen in pictures representing famous philosophers meditating on nature. Unless they are quite open the walls may be made of bamboo or basket-work. The more elaborate pavilions on a polygonal or round plan developed in connection with the Chinese garden and have been abundantly used in the imperial parks since early times. Such kiosks, tea-houses and pavilions were placed on spots with historical associations or on hills or promontories where the view was particularly beautiful. Their shape and style were developed with a view to the rockeries and the growing trees; how well they fitted into such surroundings may still be seen in the wonderful gardens around the sea palaces in Peking. These small pavilions, half hidden between the trees, clinging on the rocks or rising on stones out of the mirroring water, often give us a more vivid and immediate impression of the charm and naturalness of Chinese architecture than the larger buildings. It was also pre-eminently through such small decorative structures that Chinese architecture became known and appreciated in the 18th century in Europe.

On the larger pavilions the roofs are usually divided into two or three storeys, thus adding greatly to the picturesque effect of the building, particularly when it is erected on a polygonal plan

which gives it a number of projecting corner snouts. Beautiful examples of this kind of pavilion may be seen at the "Coal Hill" in Peking as well as in Pei Hai and other imperial parks. They have no walls, simply open colonnades supporting the roof which may give the impression of hovering in the air. When the portions between the successive roofs are enlarged and provided with balconies or colonnades the pavilion becomes a real tower, such as for instance the Fo Hsiang Ko (Buddha's Perfume Tower), which rises above the lake at the Summer palace.

Related to the pavilions by their open decorative effect, yet forming an architectural group of their own, are the *p'ai lou*, *i.e.*, free-standing gateways with three or more openings, which span the streets in many Chinese cities or mark the entrance to some sacred precincts, such as tomb or temple areas. The object of their erection was often to commemorate some outstanding local character or some important event in the history of the place or simply to mark a spot notable for its beauty or its sacredness. The earliest *p'ai lou* were, no doubt, simply large gateways made of wood and provided with inscribed tablets. These could easily be developed into more important structures by adding at the sides more posts and gateways, and they were soon executed in stone as well as in wood. From an architectural point of view they may be divided into two principal groups: the one consisting of *p'ai lou* with very tall side posts reaching above the transversal beams (which may be covered by small roofs); the other, of *p'ai lou* with shorter side posts covered by the roofs, so that the whole gateway has more likeness to a façade or an open flat pavilion. The supporting masts, which may be 4 or 8 or 12 according to the size and importance of the structure, are placed on stone plinths, sometimes decorated with lions, and tied together not only by cross-beams in two or three horizontal rows, but also by carved or painted panels or, in the case of stone *p'ai lou*, by flat slabs decorated with reliefs. Over each one of the openings is a separate small span-roof resting on brackets and usually covered with glazed pan-tiles. The *p'ai lou* thus contain some of the most characteristic features of traditional Chinese architecture, *viz.*, the supporting posts, the curving saddle-roofs on double or triple rows of brackets, and the carved or painted friezes. They are essentially wooden structures. The whole character of these buildings as well as their decoration has been developed with a view to the special requirements of the material, but that has not prevented the Chinese from

BRACKETING SYSTEM ON BELL-TOWER AT SHAO LIN SSU. YÜAN PERIOD

executing the same type of structure also in brick and in stone. The largest among them stand at the Ming tombs near Nankow and at the tombs of the Ch'ing emperors at Hsi Ling and Tung Ling, but the most elaborately decorated marble *p'ai lou* may be seen in some of the old cities in Shantung, such as Chüfu and Weihsen.

Closely connected with the *p'ai lou* are those highly decorative sham façades which used to be erected in front of important shops. They also consist of tall masts tied by cross-beams with manifold rows of brackets which support small roofs in one or two storeys.

Under these are panels decorated with human figures in relief or with brightly coloured floral designs in open-work into which the signboards of the shops are inserted. High masts or pillars are indeed much in favour in China; they are mostly used pair-wise, either free-standing in front of palaces (as the *hua piao*) or at the gateways of the dwelling compounds. Another type of gateway which is quite common consists of broad pillars made of masonry

BRACKETING SYSTEM FROM THE CH'U TZU AN, SHAO LIN SSU. SUNG STYLE

and coated with glazed tiles, often with ornaments in various colours. When a span-roof connects the deep pillars a kind of small gatehouse may be created.

Of considerable importance also for the outward effect of the Chinese buildings are the balustrades which line the terraces and staircases in front of the buildings. They are in northern China mostly made of white marble and composed of square posts ending in sculptured finials between which ornamented panels and moulded railings are inserted. Such marble balustrades may be seen at most of the important temples and, in their richest development, on the terraces of the Three Great Halls (San Ta T'ien) in the Forbidden City in Peking. Here they are repeated in three different tiers and broken in many angles, according to the shape of the terraces, producing a splendid decorative effect, particularly as the white marble stands out in contrast to the red colour of the buildings.

Stone and Brick Buildings.—Although Chinese architecture is principally wood construction, it should not be forgotten that a great number of stone and brick buildings have been made in China, including bridges, for which the Chinese since earliest times have used brick and stone. The great majority of the still existing buildings in masonry are of comparatively late periods; very few indeed can be dated before the Wan Li era (1573-1619). The only important exceptions to this general rule are the pagodas made of brick and mud, several of which may be ascribed to the T'ang period (618-906) and a few to even earlier times. On the whole, it seems, however, that the Chinese regarded brick and stone work as material fitted for storehouses, walls, substructures and the like, but hardly for real architecture in the same sense as wood construction. It is a characteristic fact that brick buildings are not even mentioned in the standard work on architecture which was published by imperial order in the year 1103 under the title *Ying Tsao Fa Shih* (The Method of Architecture). This beautifully illustrated work in eight volumes (which has been issued in a modern reprint) is founded on the practical experience of architects and decorators, which the author, Li Chieh, collected from various sources. It gives everything that an educated Chinese towards the end of the Sung period considered the fundamentals of architecture. No stone or brick houses are mentioned, not even columns, door-frames or floors of stone. The only stoneworks particularly described are the plinths and corner pilasters, stairs, balustrades, dragon heads on staircases, thresholds and stones for the door-posts, besides canals, sluices, platforms, terraces, etc. The measures and instructions for the execution of all these various kinds of stonework are very accurate, but they are of no great

importance for the architectural style. The constructive methods are treated only in the third part of the book, which contains "Rules for large work in wood," i.e., framework of buildings, posts, trusses, rafters, etc. Then follows a chapter called "Rules for smaller works in wood," i.e., doors, windows, partition walls, coffered ceilings, screens, cornices, gutters, staircases, door-panels, balustrades, besides Buddhist and Taoist house shrines, or *Fe yüeh*, decorative gate-façades erected in front of important houses, etc. Then follow "Rules for works in carved wood," concerning decorative details, and at the end of the book, "Rules for exterior roofing," also concerning the ornamental figures on the roofs, etc. The author devotes some paragraphs to bricks and to roof tiles but he gives no rules for construction in such materials.

Turning to the existing monuments in China, we may notice the Ssu Men Ta, at the temple Shen Tung Ssu in Shantung, as the earliest and most important example of architectural masonry work. The building, which in spite of its name—the Four-Gate pagoda—is no tower but a one-storeyed square house (each side about 7.35 metres), was erected A.D. 534. It is coated with finely cut and fluted limestone slabs, but the interior body of the walls may be partly of mud. It has an arched entrance on each side and a cornice consisting of five corbelled tiers but no other architectural divisions. The pyramidal roof is made of corbelled stone slabs and supported by a large square centre pillar crowned by a small stupa. The solid and self-contained aspect of the building together with its fine proportions make it one of the most remarkable of Chinese architectural monuments. It is possible that similar buildings existed in earlier times when stone and brick may have been more freely used; the type may be observed, for instance, in the more or less house-shaped tomb pillars of the Han dynasty in Szechuan and Honan.

The next in date among the masonry buildings are some real towers or pagodas of the Sui and T'ang periods which will be mentioned later; most of them are made of packed clay or dirt in combination with stone or brick. Still more common is the combination of brick and wood construction. It can be carried out in different ways, either by lining a real wooden structure with brick walls or by placing a bracketed span-roof on strong brick walls, eventually adding pillars for interior support if the walls are too wide apart. This method of construction has been used in most of the outer city gate-towers, of which the oldest now preserved are from the beginning of the Ming period, and also in numerous watchtowers and storehouses on the walls that enclose the cities of northern China. A particularly fine example is the famous bell tower at Peking, often considered as a monument of the Yuan dynasty, though it was completely renewed during the reign of Chi'en Lung. All these buildings exhibit on the outside massive brick walls more or less regularly divided by windows or by rows of square loopholes which give to the battered façades of the big gate-towers a fortress-like appearance. The shape of the high roofs is, however, the same as on ordinary wooden structures, and if one examines these masonry buildings more closely, one usually finds wooden columns inserted in the walls as well as detached in the interiors.

The substructures of the gate and bell towers are in most cases pierced by tunnels or barrel vaults serving as passages. These may be either round or somewhat pointed, as for instance on the drum tower in Peking which actually dates from the Yuan period. The vaults are constructed with great care and precision, sometimes reaching a span of nearly 15 metres. Vaulting (but not the system of *voussoirs*) was undoubtedly known in China in early times; it was used in the tomb chambers which were covered with bricks, in the tunnels leading to these; when heavy brick walls were erected around the cities, barrel vaults followed suit for the entrances. The step from such constructions in brick to the building of cupolas is not a very long one. We do not know exactly when cupolas first came into use, but we have reason to assume that they were well developed in the T'ang period. As an evidence of this the mosque in Hangchow may be mentioned because the farthest rooms of this building are covered by three cupolas on pendentives (*q.v.*). The mosque may have been renewed in later times but in close adherence to the original model which, of course,

TWO HALLS IN PEKING

1. Pao Ho Tien, one of the Three Great Halls, in the Purple Forbidden City, Peking; built 1627, repaired 1765
2. The Hall of Classics, at the Confucius Temple, Peking. The upturned

lines of roof corners suggest aspiration, as, in another form, the Gothic is said to do. The tent form is sometimes regarded as the possible origin of the characteristic shape of Chinese roofs

was of Persian origin. Another kind of cupola is to be found over the hall of the big bronze elephant on the Omi mountain in Szechuan erected during the reign of Wan Li (1573-1619). The transition of the square room into a round cupola is here also accomplished by means of pendentives but outwardly the building is covered by a tent-shaped roof. One of the small sanctuaries on Piao shan near Tsinanfu is an example of a more pointed cupola.

BRACKETING SYSTEM OF CHIEN CH'ING KUNG, FORBIDDEN CITY, PEKING

At the end of the Ming period buildings with classical orders in one or two storeys began to appear. Internally these were covered by longitudinal or transversal barrel vaults, but outwardly they were provided with the usual span and shed-roofs. Among the best examples of this kind of building may be mentioned the Wu Liang Tien in Suchow and Shuan Ta Ssu in Tai-yuanfu, besides the two halls on Wu Tai Shan. The façades are divided by arches and columns, but these are partly inserted in the wall and the capitals are stunted or turned into cantilevers, the entablature reduced to an architrave, the cornice replaced by rows of brackets above which the upturned eaves project in the usual manner. This combination of classical orders and Chinese brackets is indeed characteristic evidence of how foreign the principles of Greek architecture always remained to the Chinese. Such buildings may have been inspired by Indian models, but the Chinese modified them quite freely by grafting on the pseudo-classical models elements inherited from their indigenous wooden architecture.

An entirely different type of masonry work is illustrated by the buildings made after Tibetan models mostly as late as in Ch'ien Lung's reign. The towers and sham fortresses on the slopes of the Western hills in Peking, which were erected in order to give the Chinese soldiers an opportunity to practise assaults, are well known by all tourists. Still larger and more important Tibetan buildings may be seen at Jehol, the famous summer resort of the Manchu emperors in northern Chihli, where an entire Llama cloister was erected after the model of the famous Potala in Lassa, the residence of the Tibetan pope-kings. This enormous brick façade in some nine or ten storeys must in its absolute bareness have appeared quite dreary to the Chinese. They have tried to give it some life or colour by surrounding the windows with pilasters and canopies made of glazed tiles, but the sombre and solid character still dominates, giving evidence of a foreign culture transplanted into Chinese surroundings.

Historical Development.—Buddhist temples and pagodas have existed in China since the end of the Han dynasty, and though the earliest ones are no longer preserved, we may obtain some idea about them from old reproductions and contemporary Japanese buildings made after Chinese models. The first messages of the new religion were brought to the Chinese at the beginning of our era, but it was not until the 2nd century A.D. that it became more widely spread, largely due to the pilgrims who journeyed between China and India. They brought news not only of the writings and images of the new religion but also of its buildings. It has been reported that small bronze models of the famous stūpa of Kanishka at Peshawar (erected in the 1st century A.D.) were brought to China by Hui Sheng, a monk who took part in a mission to India in the year 518. No doubt, other pilgrims did the same, and there may have been many small models of this much admired religious monument in China. As far as one may judge by later Indian reproductions, reverting more

or less directly to the famous pagoda of Kanishka, it was built on a square platform, but the main section of it seems to have been round or bottle-shaped and divided by projecting cornices into three or more storeys. Very characteristic of this pagoda was the high mast with its nine superposed metal disks and crowning lotus bud. At present there are no such pagodas preserved in China, but ancient engravings on stone give us reason to believe that they have existed.

The oldest pagoda in China still standing is at Sung Yüeh Ssu, a temple on the sacred mountain Sung Shan in Honan. According to historical records, it was built about 523, when the palace previously existing here was consecrated as a temple. The tower is made of mud and brick on an octagonal base and reaches a height of nearly 30 metres. The lowest section consists of a plain plinth above which follows a main storey divided by pilasters and windows in a kind of aedicula (*g.v.*). The upper section of the tower has the shape of a convex cone, divided by narrow cornices into 15 low, blind storeys. It is crowned by a large bud or cone with nine rings, an equivalent to the mast with the metal disks which is usually found in the wooden pagodas. The early date of the building is verified by the style of the lion reliefs and the mouldings of the main storey.

The character of the whole structure is solid and severe, at the same time the incurvation of the outline prevents any impression of rigidity.

There is no other pagoda of as early date but the type returns with some modifications in some later pagodas, as for instance, the Pei T'a (the North tower) and the Nan T'a (the South tower) at Fang Shan in Chihli. The former, which was built at the beginning of the 8th century, shows a more typically Indian style with its bottle-shaped top, part being on a terraced substructure while the latter, which was built at the beginning of the 12th century, has a stiffer appearance without any incurvation of the outline or narrowing towards the top. It is divided by bracketed cornices into 11 storeys and reveals by its form and details a closer connection with traditional Chinese constructions. To the same group of buildings belong also the pagodas at Ch'engtingfu, Mu T'a (T'ien Ning Ssu) built about 1078 in nine storeys with wooden cornices, and the Ching T'a built at a somewhat later period, and furthermore the two big pagodas near Peking, known as Pa Li Chuan and T'ien Ning Ssu, which were erected during the Chin and Yüan dynasties (in the 12th and 13th centuries). They show some likeness to the Nan T'a at Fang Shan, but their dimensions are much larger and their high plinths are richly decorated with figure reliefs in baked clay. Both have 13 low blind storeys and make quite an imposing effect by their great height, but they lack the elastic incurvation which gives to the pagoda at Sung Yüeh Ssu such an harmonious character.

ROOF TILES ON A HALL IN THE FORBIDDEN CITY, PEKING

Many of the early pagodas in China were, no doubt, constructed of wood and have perished, because of the unresisting material. There are records of a very large wooden pagoda erected in A.D. 516 at Lo-yang at the order of the Empress Dowager Hu. According to Chinese chronicles this was 100ft. high (a statement which must not be taken literally but merely as a general indication of unusual height) and consisted of nine storeys. Above the tower rose a mast roof, high carrying 30 gilt metal discs which, as well as the chains by which the mast was tied to the four corners, were hung with no less than 500 gilt bells. This noble edifice became, however, the prey of fire in 534. The description must have been based on hearsay, but it nevertheless has some interest as testimony of the existence of wooden pagodas in China at an early date. It is also confirmed by several reproductions of pagodas found among the cave sculptures from the beginning of the 6th century at Yun Kang and Lung Men. Here one may see executed in relief pagodas with

three as well as with five storeys illustrating exactly the same architectural type as found in the earliest Japanese pagodas from the beginning of the following century. They are built on a square plan with corner posts and projecting roofs over the successive storeys and crowned by high masts carrying discs and ending in the form of large buds or small stūpas. In the successive storeys on some of these pagodas are placed Buddhist statues.

Excellent examples of the same type of pagoda may be seen at some of the old temples near Nara in Japan, as, for instance,

BRACKETING SYSTEM ON THE KONDO OF TOSHODAIJI. T'ANG STYLE

Horyuji and Hokkiji which were erected at the beginning of the 7th century in the Suiko period by builders from Korea or China. The pagoda at Hokkiji has five storeys; the bracketed roofs project quite far but narrow gradually towards the top so that the appearance of heaviness is avoided. Each side has four carrying posts with projecting cantilevers, which at the corners are placed diagonally and cut into the shape of clouds, a motif which is particularly characteristic of this period. The rafters are square and rather substantial; the far projection of the eaves is produced by a very clever construction which no doubt was developed in China before it was introduced in Japan, although the earliest Chinese examples no longer exist. The principle of this system consists in the redoubling of the rafters below the eaves: instead of placing the outermost purlins directly on the cantilevers, which project from the posts, supporting shorter rafters are introduced which are fastened in the beams and trusses of the roof and which carry by means of vertical struts or cushions the further projecting upper rafters. These may be made longer and the roof is lifted higher, the effect becoming lighter than in buildings where the purlins rest directly on cantilevers or beams. This constructive system with redoubled rafters remained in use until the Yüan period, perhaps even later, though the form of the lower rafters as well as other details becomes modified. Furthermore one may notice in these early buildings the very solid and broad shape of the various members, as, for instance, the comparatively short columns with entasis (*q.v.*) and the very broad and heavy cantilevers cut into the shape of clouds at their lower side. The trusses and beams of the roof, to which the rafters are tied, are solid and strong, the various parts being tied together with consummate skill.

The essential parts of the buildings and the method of construction are the same in the pagodas and in the temple halls of this period, as may be learned from a closer study of the Golden Hall or Kondo of Horyuji, an oblong, quadrangular room with a colonnade and a roof of two storeys. A very important member added to the pagodas is, however, the mast which runs through the whole height of the tower. The purpose of this mast is not really constructive, it is not meant to support the tower, but simply to form a spire rising high above the roof and carrying the nine metal rings or discs. The builders usually did not tie the mast very tightly to the framework of the tower, because if the whole structure were suspended on the mast, the security of the tower would be jeopardized by the unavoidable swaying of

the mast. In some comparatively recent examples one may find the mast suspended in the beams of the tower, but here the intention evidently was to lift it a little above the ground in order to avoid the still greater danger that might arise through the gradual sinking of the tower which would then, so to speak, be carried by the mast or hang on it. In the oldest pagodas which for the longest time have withstood storms and earthquakes the mast is a relatively free-standing post within the structure, always with plenty of room for its swayings, which thus do not really affect the security of the tower.

Quite a number of pagodas and temple halls of the 7th and 8th centuries are to be found in Japan, but it is our purpose here simply to point out certain general principles of construction borrowed from China. The five-storeyed pagoda at Horyuji is, in spite of the verandah which was added later round the ground storey, the most important example, but characteristic of the same style (which was developed in China, during the northern Wei dynasty and in Japan during the Suiko dynasty) are also the three-storeyed pagodas at Hokkiji and Horinji, which remind us of the stone reliefs representing pagodas in the grottoes at Lung Men and Yun Kang.

Important modifications of the old style may be observed on the beautiful pagoda of Yakushiji which was erected at the beginning of the 8th century in close adherence to Chinese constructions from the beginning of the T'ang period. It is a three-storeyed tower, but each one of the storeys is provided with a closed balcony carried on cantilevers, so that the pagoda at first sight gives the impression of a six-storeyed building. The intermediate shed-roofs are of the same shape, though smaller than those which cover the main storeys; a kind of rhythmic division is thus created, and the decorative effect becomes more interesting than in the earlier pagodas. Of great importance for the horizontal articulation are also the far-projecting carrying beams of the balconies, as well as the repetition of the three-armed brackets in double tiers under the eaves of the six successive roofs. The bracketing system has here attained its highest development, the lower brackets being used as supports for the upper ones which reach farther out and are provided with cushions. Their transversal arms replace the formerly used cantilevers, and on the top of them may be one more tier of similarly shaped brackets, as on other buildings of the same period. It should be observed that all the brackets are complete, the lower ones being so arranged that they carry a continuous beam and also the trans-

versal arms of the upper brackets, while these serve as supports for the upper beams under the eaves and for the rafters. In order to strengthen the vertical construction, struts with cushions are often placed on the hammer-beams in the intervals between the brackets.

The same characteristic forms and constructive features return in some contemporary temples and pagodas which thus also testify that the parts to which we have paid special attention are typical features of the architecture of this period. Interesting in this connection are the two large temple halls at Toshodaiji, another temple not far from

OUTER GATEWAY ACCORDING TO YING TSAO FA SHIH (1103)

Nara, *i.e.*, the Kodo (Hall of Teaching) and the Kondo (the Golden Hall). The former once formed a part of the imperial palace at Nara but was moved to its present place when the temple was erected in 759. The building is quite simple, an oblong, one-storeyed hall with double rows of columns all around, the inner row standing free in the room, the outer being filled out to form a wall. The columns are not quite as heavy as on the buildings of the preceding period and the inter-columns are very long. The brackets are introduced only in one tier but between them are struts which contribute to support the roof.

The same principles of construction are still further developed on the Kondo of Toshodaiji which, with the exception of its entirely rebuilt roof, is an unusually imposing example of T'ang architecture. The building stands on a comparatively broad and high platform, but it is provided with a colonnade only on the front. The columns have a slight entasis and rest on moulded plinths. They are tied together, as usual, by a long architrave-beam and provided with quadrangular cushions from which the three-armed brackets project. These carry the upper longitudinal beam and a second tier of brackets. Above this follows a third row of brackets which is almost hidden below the far projecting eaves. The rafters project between the arms of the uppermost brackets and abut against the transversal arms of the second row of brackets. The rafters are doubled, the upper ones being supported by struts which also carry the outermost purlins, and the two layers are furthermore tied by braces. The whole system is carried out with perfect logic in a method which may be termed the highest perfection of wooden construction.

How closely this building depends on Chinese models is proved by the reproduction of a similar temple hall on a large stone gable above one of the gateways to the Ta Yen T'a pagoda at Sianfu. This remarkable engraving which we reproduce from a copy executed by a Japanese artist for Prof. Sekino, is of great historical importance, because it evidently reproduces a Chinese temple on which we may observe the same constructive details as pointed out on the Kondo of Toshodaiji. It matters little that the columns have been made spiky and the roof too small, as long as we recognize the principle of the whole constructive system, *i.e.*, the brackets and the struts, of which the lower ones have the same kind of curving legs as may be seen on some Japanese buildings of the 9th and 10th centuries.

Before following the further development of the traditional wooden construction during the Sung and the Yüan dynasties it is necessary to mention a group of buildings which illustrates another side of T'ang architecture. These are pagodas in what is popularly called the "Indian style," that is to say, buildings made of packed mud and brickwork which rise in terraces on a square plan. The most important among these pagodas stand in the neighbourhood of Sianfu within or just outside the district which once was occupied by Ch'angan, the capital of the T'ang emperors. In the first place should be mentioned the Ta Yen T'a (the Large Pagoda of the Wild Geese) which was founded in the year 652 by the great Buddhist pilgrim and teacher, Hsüan Chuang. It was then made of clay and brick in five storeys; later on, though still in the T'ang period, some storeys were added, and after some vicissitudes, the tower was rebuilt between 931 and 933. Later repairs have been carried out in the Ming and Ch'ing periods. The present pagoda, which has five storeys, seems however to correspond quite well to the T'ang building. It stands on a fairly high terrace and is at the base about 25.5 metres square, its full height being almost 60 metres. Its general shape reminds us of an elongated pyramid with truncated top. The successive storeys, which are accentuated by corbelled cornices, grow lower and narrower towards the top. The uppermost has a pyramidal roof crowned by a glazed cone which is now well covered by small trees and bushes. The coating of the walls is made of yellowish, lightly burnt bricks. They are quite plain except for some very thin pilasters and the arched gateways and a window on each side. The interior division is made by beams and wooden floors and the staircase which still exists makes it possible to ascend to the top. The imposing effect of this tower depends on its fine proportions and well balanced, massive form, which is strengthened by its position on a natural elevation.

Not far from this stands a smaller pagoda called Hsiao Yen T'a (the Small Tower of the Wild Geese), erected 707-709. This tower had originally 15 storeys but of these hardly 13 are now preserved. The storeys are very low but, as in the previous instance, accentuated by corbelled cornices. Only the ground floor is a little higher and on the northern and southern side provided with vaulted entrances. The upper storeys have small vaulted windows on the façade but otherwise no openings or divisions, and it is impossible to know whether they ever had any floors be-

cause there is no longer any staircase. Externally the tower differs from the Ta Yen T'a by the fact that it is not a stepped pyramid but a square tower with a slight curve on its middle part.

In still worse repair is the Hsiang Chi Ssu, situated a little farther southward from Sianfu. It was erected in 681 according to the same general design as Hsiao Yen T'a, probably in 11 or more storeys, of which, however, only ten remain. The outline

P'ING TZU MEN, INNER GATE-TOWER, PEKING

is not curved but rises straight towards the top which is largely ruined. The storeys are quite low but provided with an horizontal and vertical moulding possibly suggested by wooden buildings. The dependence on wooden architecture is still more evident in another pagoda situated in the same neighbourhood called Hsing Chiao Ssu, which was erected in 839 at the place where the remains of the great pilgrim, Hsüan Chuang, were removed in 669. It is a comparatively small tower measuring only about 20 metres in height and 5.35 on each side, but it presents an unusual historical interest by the fact that some of the most characteristic elements of wooden architecture have here been faithfully reproduced in brickwork. The storeys are not only marked by corbelled cornices but also with rows of three-armed brackets which rise from a kind of horizontal beam and provided furthermore, in the two upper storeys, with carrying posts in the shape of half columns. This close adherence to wood constructions may also be taken as an evidence of the greater age of the wooden pagodas in China as compared with the brick pagodas, which probably were developed through influence from India.

On each side of the Hsing Chia Ssu are smaller three-storeyed pagodas erected to the memory of other monks, both having three divisions without any cornices. Such minor quadrangular towers of three to five storeys dating from the T'ang, Sung and Yüan dynasties are often to be found on tombs or other memorable places. One of the largest and most beautiful among them is the Pai T'a Ssu in the same neighbourhood south of Sianfu; others are to be found at Shen Tung Ssu in Shantung and at Fang Shan in Chihli. The same architectural shape may also be observed in the celebrated pagoda Pai Ma Ssu near Honanfu which was not built until the Sung period, though it often has been mentioned as one of the oldest pagodas in China, probably owing to the legend connected with the Pai Ma Ssu temple. It is supposed to have

been founded by Indian missionaries, who carried the first *sutras* to China, but as a matter of fact, the present pagoda was preceded by an earlier one in wood, which perished by fire in 1126. Other characteristic buildings are the Chiu T'a Ssu, or Nine-towered Pagoda, near Lin Cheng in Shantung, and the Lung Kung T'a at Shen Tung Ssu, an impressive square tower in three high divisions, which are encumbered by sculptural decoration.

CROSS SECTION AND ELEVATION OF YAKUSHIJI PAGODA. 8TH CENTURY

Although the greater part of the buildings which still remain in China from the T'ang and Sung dynasties are pagodas made of mud and brick there are also some examples of temples constructed at least in part of wood, dating from the end of the Sung period. The most authentic and important of these is the Ch'u Tzu An hall at Shao Lin Ssu, the famous temple on the slope of Sung Shan in Honan, where the miraculous Bhodidharma, the founder of the Dhyana or Zen Buddhism, is said to have remained several years. According to an inscription, the Ch'u Tzu An was erected about the year 1125 or shortly before. It is a small, square building (measuring about 11 metres on each side) standing, as usual, on a stone terrace. Each side has four hexagonal stone pillars but only those of the façade are even partly visible, the others being

completely embedded in the brick walls. In the room are two pairs of smaller and two pairs of larger hexagonal pillars, all decorated with Buddhist reliefs, and the gateway is framed by carved stone beams. Thanks to these solid stone supports the building still stands, but the roof, which is made of wood, threatens to fall in (if it has not already done so). At the writer's visit to the place in 1921 large pieces of the eaves were missing, and perhaps now the building has no other roof than the sky. The most interesting parts of this structure, however, are not the carved stone pillars but the brackets under the eaves which illustrate how these were used in the Sung period. The modifications in comparison with the bracketing system of the T'ang dynasty are quite noteworthy. Thus we find that the brackets emerge not only from the pillars but also, between these, from the horizontal beam. They are placed more closely together than previously, forming a kind of cornice. In the lower tier the brackets have three arms but in the upper tier the transversal arms have been cut by the under rafters, which are pointed and project like beaks or long paws. They are tied by means of braces to the brackets and carry at both ends struts (vertical posts) on which the purlins or corresponding beams rest. This change may be said to imply that the lower rafters have lost their original character and become a sloping cantilever transversing the lower brackets which they lengthen, thus making them better fitted to support the far projecting roof. The modification has evidently a practical purpose, though it hardly improves the original bracketing system, as exemplified on the T'ang buildings.

The evolution continued in this same direction; the three-armed constructive brackets gave place to two-armed ones transversed by thin sloping beams or rafters, cut like beaks at the end. These project successively, the one tier reaching beyond the other, each one carrying its row of brackets which serve to support the longitudinal beams or a kind of struts for the purlins. The former system may be observed on the Bell Tower at Hsiao Lin Ssu, which according to an inscription was erected about the year 1300, where the third storey has no less than four tiers of gradually projecting brackets with beaks. The latter method is quite common; as an example may be mentioned one of the pavilions at the Confucius temple at Chüfu, also of the Yüan dynasty, where the horizontal pieces form a support for several sloping cantilevers (or rudimentary lower rafters) which have been joined into a kind of bed for the struts and purlins of the roof.

Chinese buildings dating from the Sung and Yüan dynasties are scarce indeed, but our knowledge of the architecture of these

CROSS SECTION OF THE KONDO OF HORYUJI, BUILT IN 7TH CENTURY

times may be supplemented by observations on Japanese buildings from the 12th and 13th centuries, *i.e.*, the Kamakura period. In Japan this was a time of great building activity and, according to the best informed Japanese authorities, remarkable for its close imitation of the contemporary Chinese models. Quite important in this respect is the Shariden (Chu Tzu An) of the Zen temple Engakuji in Kamakura, built according to the same principles as the above-mentioned Chinese hall, though with an

CHINESE MEMORIAL GATEWAYS

1. P'ai-lou or memorial gateway built of wood, at the lake of the Summer Palace, Peking. These characteristic structures, usually of wood, mark the entrance to a sacred or beautiful spot or commemorate some event or person
2. Marble P'ai-lou at the Altar of Heaven, Peking. This illustrates the type

- of p'ai-lous with tall side-posts reaching above the transverse beams
3. Marble P'ai-lou over the main street in Wei-hsien, Shantung. In this type of p'ai-lous, the shorter side-posts are covered by roofs, making the gateway resemble an open pavilion. This is one of the more elaborate examples, with three openings and storeyed roofs

extraordinarily large and high roof covered with straw. This is carried by brackets of the same type as those which were observed at Chu Tsu An of Hsiao Lin Ssu. The brackets are placed so closely together that they form a continuous cornice. The purely Chinese origin of the constructive system of the Shariden of Engakuji may be confirmed through a comparison with some of the illustrations in the above-mentioned architectural treatise *Ying Tsao Fa Shih* published in 1103. On the buildings or schematic designs reproduced here we find brackets of exactly the same type as those described above, though their significance is partly obscured by the addition of some large transverse beams which probably have their origin in the imagination of the draughtsman.

The Japanese called this constructive system which they have borrowed from northern China, "karayo," while another somewhat different contemporary method was called "tenjiku," because it was considered to have been derived from India via southern China. It was used principally at large gates and temple buildings, to which one desired to give a particularly imposing appearance by the development of their upper portions. This was achieved by multiplying the brackets and transforming them into straight arms or cantilevers projecting stepwise from the posts. A good example of the *tenjiku* style is the Nandaimon gate at Todaiji, which was erected in 1199. It has five spans of columns on the long sides and a roof in two storeys, of which the lower one is supported by seven tiers and the upper by six tiers of cantilevers projecting from each column. At the corners are added diagonal cantilevers to form a support for the corner beaks. This kind of construction seems, however, never to have won much popularity in northern China; it is so simple and natural that it hardly can be credited with particular artistic importance. Projecting roof beams have indeed been used in many countries to support the eaves, but the characteristic feature of the *tenjiku* buildings is that the cantilevers are multiplied or massed together by the insertion of intermediate pieces into large composite brackets.

The further development of the wood construction in China after the end of the Yüan dynasty is a question which hardly needs

tailed investigations than have hitherto been made. It is evident however, that already during the latter half of the Ming period simpler methods were applied, as may be seen for instance on the earliest buildings in the Forbidden City in Peking. It is true that the outer appearance was kept up by fixing multiple rows of brackets and pointed beaks below the eaves, but these have no real constructive function. The purlins rest on projecting beams or on struts standing on the columns. The closely arranged and freely multiplied brackets and beaks which we find on the big palace halls and imposing gate towers in Peking are nothing but ornamental cornices, the decorative effect of which nobody will deny. The roof would indeed rest just as well on the building even if these sham brackets were taken away. The forms are still the same as before but they have lost much of their significance because they lack inner necessity. The particular quality and importance of the old architecture of China depended on its firm and clearly developed wood construction. It was purely carpenters' art, and based on the special requirements of the material. Each part had a definite function which was not concealed by any superimposed decoration. This architecture was logical and purposeful and it remained a living art as long as the original principles of construction were kept up, but once these were encroached upon by purely decorative tendencies, both vitality and further growth were at an end. (See also JAPANESE ARCHITECTURE.)

DOOR PANEL ACCORDING TO YING TSAO FA SHIH (1103)

(O. S.)

BIBLIOGRAPHY.—The only original Chinese work on architecture is the *Ying Tsao Fa Shih* (1103; 2nd ed., 1145; reissued by the Shanghai Commercial Press). Good accounts of the work were given by P. Demieville in *Bulletin de l'École Française d'Extrême-Orient*, tome xxv. (1925), and Percival W. Yetts in the *Burlington Magazine* (March, 1927), the latter containing a discussion of earlier European books dealing with Chinese architecture. Of greater importance are, however, the works published by various Japanese authorities on their own early buildings since these are closely connected with those of China. See *Japanese Temples and their Treasures* (last ed. 1915); also articles in the *Kokka* and other Japanese reviews, especially C. Ito and J. Tsuchiya's report about the imperial palaces in Peking, in the *Bulletin of the School of Engineering of the Tōkyō Imper. University* (1905), a kind of text for the portfolio publications; *Photographs of Palace Buildings of Peking and Decoration of the Palace Buildings of Peking* (1906). See also Boerschmann, *Baukunst und religiöse Kultur der Chinesen* (1911-14) and *Chinesische Architektur* (1925); Osvald Sirén, *The Walls and Gates of Peking* (1924), and *The Imperial Palaces of Peking* (Paris, 1926); Tokiwa and Sekino, *Buddhist Monuments in China* (Tōkyō, 1926-27), of which only one part has been issued in English.

The drawings of this article are executed partly on the basis of sketches by Prof. Sekino and partly after photographs by the author.

CHINESE EASTERN RAILWAY. In 1895 there was formed, under Russian charter, but with a predominance of French capital and with some capital owned by the Chinese Government, the Russo-Chinese Bank. When, in 1896, Russia obtained from China permission to shorten the Trans-Siberian railway by building a line across Northern Manchuria, the bank formed the Chinese Eastern Railway Company. Only Russians and Chinese were to be shareholders, and a Chinese appointed by Peking was to be president. After 80 years the line was to revert to China free of charge, or the Chinese Government might purchase it at the end of 36 years. The original board of directors was entirely Russian, and the capital stock was all owned by the Russo-Chinese Bank. In 1898 a convention between China and Russia provided for the construction by the company of the South Manchurian line of the Chinese Eastern railway from Harbin to Port Arthur and Dairen (Dalny). The roads so provided for were completed in 1905 and for that purpose the Russian Government advanced about 800,000,000 roubles. In 1905, as a result of the Russo-Japanese War, the South Manchurian railway south of Changchun passed into the hands of Japan.

A STONE ENGRAVING ON THE DOOR GABLE AT TA YAN T'A, SIANFU

to be discussed, because no real progress can be observed, but rather a gradual decline, which becomes evident in the more and more arbitrary treatment of the bracketing system. At the beginning of the Ming dynasty one may still find buildings constructed in the same style as those of the Yüan period, i.e., with beak-formed pieces laid transversally across the brackets, but the projecting pieces become often clumsy and out of proportion to the brackets. A fine example of early Ming architecture is the Bell Tower in Sianfu, the lower roof of which rests on a double row of brackets of the same type as those of the Yüan buildings. On the other hand, the tower of the eastern gate of T'a Tung Fu, erected in 1371, shows beak-shaped pieces projecting from very feeble brackets.

The question how long a really constructive bracketing system remained in use in China is difficult to answer without more de-

In 1910 the Russo-Chinese Bank was amalgamated with the Northern Bank to form the Russo-Asiatic Bank, and the new institution became heir of the Russo-Chinese Bank's interest in the Chinese Eastern railway. The new bank had a Russian charter, but the majority of its stock was in French hands. The Chinese Government remained a part owner. In 1915 an agreement was formed for the operation by the Chinese Eastern railway of the short private line connecting Tsitsihar and the main line, and in March, 1916, an agreement was entered into by the Russo-Asiatic Bank and the Chinese Government for the building of a line from Harbin to Blagoveshchensk with a branch from Mergen to Tsitsihar. In a treaty of July 3, 1916, Russia ceded to Japan 60m. of the Chinese Eastern railway between Changchun and the Sungari river.

The Railway and the War.—The World War and the Russian revolution and the consequent disintegration in Siberia threw the traffic and finances of the railway into confusion. In pursuance of the Chino-Japanese military agreement of 1918, made after China entered the World War, Japanese troops appeared in the Chinese Eastern railway zone.

The Chinese saw in the disturbed conditions in the north an opportunity to extend their control over the railway, and in 1920 put a Russian of their choice in charge and appointed three Chinese to vacant posts on the directorate. The Russo-Asiatic Bank protested and was supported by the French Government. Negotiations between the bank and the Chinese Government followed and an agreement was signed (Oct. 2, 1920), providing for temporary Chinese control of the railway under a directorate, five of whose members were to be elected by the bank and four by the Chinese Government.

At the Washington Conference in 1921-22, China and the Powers could not reach complete agreement about the railway, but a resolution was adopted stating that better protection should be given the railway, that the personnel should be more carefully selected, and the funds more economically used. The Powers other than China also made reservations under which the consular body in Harbin interfered when in Aug. 1923 the Chinese attempted to seize the land department of the railway.

The 1924 Agreement.—The Russo-Chinese agreement of May 31, 1924, contained a long article which, among other things, had an assurance that China might buy back the railway and a provision for a conference to settle more definitely the future of the road. Simultaneously, another agreement was adopted for the joint administration of the railway pending the final adjustment.

In 1924, in spite of unsettled conditions, the railway showed a profit in its operation of 7,365,000 gold roubles, as compared with 6,406,702 roubles in 1913.

Relations between the Soviet Government and the Chinese masters of Manchuria have not been smooth. Early in 1926 the Soviet general manager was arrested by the Chinese for alleged political use of the railway, but on an ultimatum from the Russians (Jan. 24) he was released. The dispute was renewed in 1929, but a *modus vivendi* was reached. (K. S. L.)

CHINESE IMMIGRATION. The first recorded Chinese immigrants to the United States reached San Francisco in 1848; not until 1852 did they begin to arrive in considerable numbers, when at least 18,000 were in the country. During the next eight years their numbers almost doubled. Some became miners, servants, laundrymen and farm hands; many engaged in the building of railroads. There being more work than laborers, the Chinese at first were generally welcomed, although there were protests against their free entrance, especially in California.

Although emigration to the islands of the Pacific and Indian oceans had been going on for hundreds of years, the Manchus, who ruled China after 1644, discouraged it. The ban upon emigration was lifted locally in the province of Kwangtung in 1859. In 1868 the Imperial Government reversed its non-emigration order by signing with the United States the Burlingame Treaty. The increased entry of Chinese into the United States subsequently caused economic and social difficulties. The Chinese were able to live on a lower scale than Americans or European immigrants, and were willing to do work scorned by white men.

The thrift and economy of the Chinese, their lack of desire or ability to amalgamate, the funds sent by them to China, the ultimate return thither of many, the fact that they were of a different race and culture, and that most of them were from the more unfortunate classes of China—all served to stir up jealousy, contempt and persecution throughout the West.

On November 17, 1880, a treaty was signed by the United States and China providing for the regulation or suspension of immigration, but not its absolute prohibition. The first of a series of Chinese Exclusion Acts aimed at labourers was passed May 6, 1882, and this was followed by others in later years. The application of these exclusion measures to the Hawaiian and Philippine Islands occurred in 1900 and 1902. In addition to the special legislation directed at Chinese, the latter come under the application of the general immigration laws of 1917 and 1924, and may be deported on departmental warrant if they enter the country in violation of law. The severity with which the laws have been applied has caused friction on numerous occasions.

Prior to 1924 the admissible classes of Chinese were teachers, including editors; students; travellers; merchants, including bankers, with their wives and minor children; officials of the Chinese government, with their wives, children and servants; persons whose physical condition necessitated immediate hospital treatment; persons shown by convincing proof to have been born in the United States, with their wives who were admitted not as citizens but as the wives of citizens, also their minor children; and seamen under prescribed conditions. The number of Chinese in the United States has fallen steadily since 1890 when 107,488 were reported to 1920, when but 61,639 were listed.

In the British Isles the number of Chinese has been negligible. The history of Chinese immigration into the English-speaking parts of the British Empire—notably Australia, New Zealand and Canada—has in many ways paralleled that of the United States. The first Chinese to enter Australia appear to be those who entered Queensland between 1840 and 1859, where they served as shepherds. The discovery of gold led to a considerable influx in the sixth decade of the century; in 1854 there were 2,341 Chinese in Victoria; by 1859 there were in the gold-fields some 42,000. In New South Wales by 1861 there were about 13,000. Disturbances began in 1860, the Chinese at times being driven from the fields. The Chinese question assumed political, economic and diplomatic significance during the remainder of the century. A determining factor in the federation of the Commonwealth of Australia in 1901 was the need for uniform exclusion laws. During the first year of the Union a sweeping immigration act went into effect. As amended during the next quarter of a century, this act prohibits the immigration into the country of "any person who fails to pass the dictation test." In the years 1905 to 1914 none passed. Non-permanent settlers, including merchants, travellers and students are not required to take the test. Since 1888 the number of Chinese has dropped steadily. In 1891 there were 38,077, including half-castes; by 1920 the estimated number was 20,118.

From 1908-23 four Acts were passed in New Zealand having to do with immigration restriction or exclusion. Chinese are required to obtain permits from the Minister of Customs, and pay a poll tax of one hundred pounds. Registered Chinese aliens in April 1920 numbered 2,376.

In Canada the mining of gold and the building of the Canadian Pacific Railroad encouraged Chinese immigration early in the '70s, immigration at that time being unrestricted. Since 1886 Chinese immigration has been controlled by a head tax ranging from \$50 per entrant in 1886 to \$500 after 1904. By the Chinese Immigration Act of 1923 Chinese of non-labouring classes only may enter. In 1920 it was estimated that not more than 35,000 Chinese were in the Dominion.

Hall, *Immigration in the Pacific: Analysis of Acts and Administration*; Institute of Pacific Relations, *Honolulu* (1925); R. D. McKenzie, *Oriental Exclusion* (Chicago, 1928); H. F. MacNair, *The Chinese Abroad* (Shanghai, 1924); M. R. Coolidge, *Chinese Immigration* (Boston, 1909). (H. F. MacN.)

CHINESE LANGUAGE. In treating of Chinese, it will be convenient to distinguish, broadly, the spoken from the written language because for reasons connected with the peculiar nature of the script, the two soon began to move along independent and largely divergent lines.

Although Chinese, like other living languages, must have undergone gradual changes in the past, so little can be stated with certainty about these changes that an accurate survey of its evolution is quite out of the question. Obviously a different method is required when we come to the written characters. We have hardly any clue as to how Chinese was spoken or pronounced in any given district 2,000 years ago, although there are written remains dating from long before that time; and in order to gain an insight into the structure of the characters now existing, it is necessary to trace their origin and development.

We find a number of dialects, all clearly of a common stock, yet differing widely from one another. Most of these dialects fringe the coast-line of China, and penetrate but a comparatively short way into the interior. Starting from the province of Kwangtung in the south, where the Cantonese and, farther inland, the Hakka dialects are spoken, and, proceeding northwards, we pass in succession the following dialects: Swatow, Amoy (these two may almost be regarded as one), Foochow, Wenchow, Ningpo and Wu. Farther north the great dialect popularly known as Mandarin (*Kuanhua* or "official language"), sweeps round behind the narrow strip of coast occupied by the various dialects above-mentioned, and dominates a hinterland constituting nearly four-fifths of China proper. Mandarin, of which the dialect of Peking, the capital 1421 to 1928, is now the standard form, comprises a considerable number of sub-dialects, some of them so closely allied that the speakers of one are wholly intelligible to the speakers of another, while others (e.g., the vernaculars of Yangchow, Hankow or Mid-China and Ssü-ch'uan) may almost be considered as separate dialects. Cantonese is supposed to approximate most nearly to the primitive language of antiquity, whereas Pekingese perhaps has receded farthest from it. For all practical purposes Mandarin, in the widest sense of the term, is by far the most important as the native speech of the majority of Chinese and the recognized vehicle of oral communication between all Chinese officials, even when they come from the same part of the country and speak the same *patois*. All examples of phraseology in this article will therefore be given in Pekingese.

The dialects proceed from the same parent stem, are spoken by members of the same race, are united by the bond of writing, the common possession of all, and share alike in the two most salient features of Chinese as a whole: (1) they are all monosyllabic, that is, each individual word consists of only one syllable; and (2) they are strikingly poor in vocables, or separate sounds for the conveyance of speech. The number of these vocables varies from between 800 and 900 in Cantonese to no more than 420 in the vernacular of Peking. This scanty number is eked out by interposing an aspirate between certain initial consonants and the vowel, so that for instance *p'u* is distinguished from *pu*. The latter is pronounced with little or no emission of breath, the "p" approximating the farther north one goes (e.g., at Niuchwang) more closely to a "b." The aspirated *p'u* is pronounced more like our interjection "Pooh!" The number of vocables in Pekingese has slowly but surely diminished. Thus the initials *t* and *k*, when followed by the vowel *i* (with its continental value) have gradually become softer and more assimilated to each other, and are now both pronounced *ch*. Again, all consonantal endings in *t* and *k*, such as survive in Cantonese and other dialects, have entirely disappeared from Pekingese, and *n* and *ng* are the only final consonants remaining. Vowel sounds, on the other hand, have been proportionately developed, such compounds as *ao*, *ia*, *iao*, *iu*, *ie*, *ua* occurring with especial frequency. One and the same sound has therefore to do duty for different words. Some sounds may have fewer meanings than ten attached to them, but others will have many more. Thus

the following represent only a fraction of the total number of words pronounced *shih* (something like the "shi" in shirt): 史 "history," 使 "to employ," 屍 "a corpse," 市 "a market," 師 "an army," 獅 "a lion," 侍 "to rely on," 待 "to wait on," 詩 "poetry," 時 "time," 識 "to know," 施 "to bestow," 是 "to be," 實 "solid," 失 "to lose," 示 "to proclaim," 視 "to look at," 十 "ten," 拾 "to pick up," 石 "stone," 世 "generation," 食 "to eat," 室 "a house," 氏 "a clan," 始 "beginning," 釋 "to let go," 試 "to test," 事 "affair," 勢 "power," 士 "officer," 誓 "to swear," 逝 "to pass away," 適 "to happen."

Use of Couplets.—To supplement this deficiency of sounds several devices are employed through the combination of which confusion is avoided. One of these devices is the coupling of words in pairs in order to express a single idea. There is a word 哥 *ko* which means "elder brother." But in speaking, the sound *ko* alone would not always be easily understood in this sense. One must either reduplicate it and say *ko-ko*, or prefix 大 (*ta*, "great") and say *ta-ko*. Simple reduplication is mostly confined to family appellations and such adverbial phrases as 慢慢 *man-man*, "slowly." But in a much larger class of pairs, each of the two components has the same meaning. Examples are: 恐怕 *k'ung-p'a*, "to be afraid," 告訴 *kao-su*, "to tell," 樹木 *shu-mu*, "tree," 皮膚 *p'i-fu*, "skin," 滿盈 *man-ying*, "full," 孤獨 *ku-tu*, "solitary." Sometimes the two parts are not exactly synonymous, but together make up the sense required. Thus in 衣裳 *i-shang*, "clothes," *i* denotes more particularly clothes worn on the upper part of the body, and *shang* those on the lower part. In another very large class of expressions, the first word serves to limit and determine the special meaning of the second: 奶皮 "milk-skin," "cream"; 火腿 "fire-leg," "ham"; 燈籠 "lamp-cage," "lantern"; 海腰 "sea-waist," "strait." There are, besides, a number of phrases which are harder to classify. Thus, 虎 *hu* means "tiger." But in any case where ambiguity might arise, *lao-hu*, "old tiger," is used instead of the monosyllable. 狐 (another *hu*) is "fox," and 狸 *li*, an animal belonging to the smaller cat tribe. Together, *hu-li*, they form the usual term for fox. 知道 *chih tao* is literally "to know the way," but has come to be used simply for the verb "to know." These pairs or two-word phrases are of such frequent occurrence, that the Chinese spoken language might almost be described as bi-syllabic. Suffixes or enclitics are attached to many of the commonest nouns. 女 *nü* is the word for "girl," but in speech 女子 *nü-tzu* or 女兒 *nü-erh* is the form used. 子 and 兒 both mean child, and must originally have been diminutives. The suffix 兒 belongs especially to the Peking vernacular. The use of numeratives is quite a distinctive feature of the language. The commonest of them, 個 *ko*, can be used indifferently in connection with almost any class of things, animal, vegetable or mineral. But there are other numeratives (at least 20 or 30 in everyday use) which are strictly reserved for limited classes of things with specific attributes. 枚 *mei*, for instance, is the numerative of circular objects such as coins and rings; 顆 *k'o* of small globular objects—pearls, grains of rice, etc.; 口 *k'ou* classifies things which have a mouth—bags, boxes and so forth; 件 *chien* is used of all kinds of affairs; 張 *chang* of chairs and sheets of paper; 隻 *chih* (literally half a pair) is the numerative for various animals, parts of the body, articles of clothing and ships; 把 *pa* for things which are grasped by a handle, such as fans and knives.

The Tones.—The tones may be defined as regular modulations of the voice by means of which different inflections can be imparted to the same sound. To the foreign ear, a Chinese sentence spoken slowly with the tones clearly brought out has a certain sing-song effect. It is absurd to suppose the tones were deliberately invented in order to fit each written character with a separate sound. It is considered that tones were the automatic result of the elision of prefixes, some of which as elsewhere may have served as classifiers. A tone is as much an integral part of the word to which it belongs as the sound itself; like the sound, too, it is not fixed once and for all, but is in a constant, though

very gradual state of evolution. This is proved by the great differences of intonation in the dialects. Theoretically, four tones have been distinguished (the even, the rising, the sinking and the entering) each of which falls again into an upper and a lower series. But only the Cantonese dialect possesses all these eight varieties of tone (to which a ninth has been added), while Pekingese has only four: the even upper, the even lower, the rising and the sinking. It appears that down to the 3rd century B.C. the only tones distinguished were the 平 "even," 上 "rising" and 入 "entering." Between that date and the 4th century A.D. the 去 sinking tone was developed. In the 11th century the even tone was divided into upper and lower, and a little later the entering tone finally disappeared from Pekingese. For centuries their existence was unsuspected, the first systematic classification of them being associated with the name of Shên Yo, a scholar who lived A.D. 441-513. The Emperor Wu Ti one day said to him: "Come, tell me, what are these famous four tones?" "They are 天子聖哲 whatever your Majesty pleases to make them," replied Shên Yo, skilfully selecting for his answer four words which illustrated, and in the usual order, the four tones in question. Not every single word in a sentence must necessarily be given its full tonic force. Quite a number of words, such as the enclitics, are not intonated at all. In others the degree of emphasis depends partly on the tone itself, partly on its position in the sentence. In Pekingese the 3rd tone (really the 2nd in the ordinary series, the 1st being subdivided into upper and lower) is particularly important, and next to it in this respect comes the 2nd (that is, the lower even, or 2nd division of the 1st). It may be said, roughly, that any speaker whose 2nd and 3rd tones are correct will at any rate be understood, even if the 1st and 4th are slurred over.

The Characters.—A page of printed Chinese or carefully written manuscript consists of a number of wholly independent units, each of which would fit into a small square, and is called a character. These characters are arranged in columns, beginning on the right-hand side of the page and running from top to bottom. They are *words*, standing for articulate sounds expressing root-ideas, but, unlike our words, are not composed of alphabetical elements or letters. Clearly, if each character were a distinct and arbitrarily constructed symbol, only those gifted with exceptional powers of memory could ever hope to read or write with fluency. This, however, is far from being the case. Most Chinese characters are susceptible of some kind of analysis. Means of communication other than oral began with the use of knotted cords, similar to the *quipus* (q.v.) of ancient Mexico and Peru, and were displaced later on by the practice of notching or scoring rude marks on wood, bamboo and stone. The first four numerals, as written with simple horizontal strokes date from this early period. In Chinese writing, a few characters, even in their present form are pictures of objects, pure and simple. Thus, for "sun" the ancient Chinese drew a circle with a dot in it: ☉, now modified into 日; for "moon" 月, now 月; for "God" they drew the anthropomorphic figure 天, which in its modern form appears as 天; for "mountains" 山, now 山; for "child" 子, now 子; for "fish" 魚, now 魚; for "mouth" a round hole, now 口; 手 for "hand" now 手; for "well" 井, now written without the dot. These picture-characters, then, accumulated little by little, until they comprised all the common objects which could be easily and rapidly delineated—sun, moon, stars, various animals, certain parts of the body, tree, grass and so forth to the number of two or three hundred. The next step was to a few compound pictograms: 旦 the sun just above the horizon="dawn"; 林 trees side by side="a forest"; 舌 a mouth with something solid coming out of it="the tongue"; 言 a mouth with vapour or breath coming out of it="words."

While writing was still in its infancy, it must have occurred to the Chinese to join together two or more pictorial characters in order that their association might suggest to the mind some

third thing or idea. "Sun" and "moon" combined in this way make the character 明, which means "bright"; woman and child make 好 "good"; "fields" and "strength" (that is, labour in the fields) produce the character 男 "male"; the "sun" seen through "trees" 東 designates the east; 家 has been explained as (1) a "pig" under a "roof," the Chinese idea, common to the Irish peasant, of home, and also (2) as "several persons" under "a roof," in the same sense; a "woman" under a "roof" makes the character 安 "peace"; "words" and "tongue" 話 naturally suggest "speech"; two hands (友, in the old form 𠂇) indicate friendship; "woman" and "birth" 姓="born of a woman," means "clan-name," showing that the ancient Chinese traced through the mother and not through the father. This class of characters, correctly called ideograms, as representing ideas and not objects, is comparatively small. As there was nothing in the character *per se* which gave the slightest clue to the sound of the word it represented, each character had to be learned and recognized by a separate effort of memory. The first step in a new, and, ultimately the right direction, was the borrowing of a character already in use to represent another word identical in sound, though different in meaning. Owing to the scarcity of vocables there might be as many as ten different words in common use, each pronounced *fang*. Out of those ten only one, we will suppose, had a character assigned to it—viz., 方 "square" (originally said to be a picture of two boats joined together). But among the other nine was *fang*, meaning "street" or "locality," in such common use that it became necessary to have some means of writing it. Instead of inventing an altogether new character, as they might have done, the Chinese took 方 "square" and used it also in the sense of "locality." This was a simple expedient, no doubt, but one that applied on a large scale would lead to confusion. The difficulty which presented itself was overcome as in speech by adding to *fang* "square," another part meaning "earth," in order to show that the *fang* in question had to do with location on the earth's surface. The whole character thus appeared as 坊. Nothing was easier now than to provide signs for the other words pronounced *fang*. "A room" was 房 door-*fang*; "to spin" was 紡 silk-*fang*; "fragrant" was 芳 herb-*fang*; "to enquire" was 訪 words-*fang*; "an embankment," and hence "to guard against," was 防 mound-*fang*; "to hinder" was 妨 woman-*fang*. This class of characters, which constitutes at least nine-tenths of the language, has received the convenient name of *phonograms*. The formation of the phonogram, or phonetic compound, did not always proceed along such simple lines as in the examples given above. In the first place, most of the phonetics now existing are not simple pictograms, but themselves more or less complex characters made up in a variety of ways. Again, the sound is in most cases given by no means exactly by the so-called phonetic, a fact chiefly due to the pronunciation having undergone changes which the written character was incapable of recording. There are extreme cases in which a phonetic provides hardly any clue at all as to the sound of its derivatives. In general, the "final" or rhyme is pretty accurately indicated, while in not a few cases the phonetic does give the exact sound for all its derivatives. A considerable number of phonetics are nearly or entirely obsolete as separate characters, although their family of derivatives may be a very large one. 𠂇, for instance, is never seen by itself, yet 堅 緊, and 賢 are among the most important characters in the language.

The whole body of Chinese characters, then, may conveniently be divided up, for philological purposes, into pictograms, ideograms and phonograms. The first are pictures of objects, the second are composite symbols standing for abstract ideas, the third are compound characters of which the more important element simply represents a spoken sound. In a strict sense, even the first two classes do not directly represent either objects or ideas, but rather stand for sounds by which these objects and ideas have previously been expressed. It may, in fact, be said that Chinese characters are "nothing but a number of more or

less ingenious devices for suggesting spoken words to a reader."

The "Six Scripts"—The Chinese themselves at a very early date (probably many centuries B.C.) evolved a six-fold classification of characters, the so-called 六書 *liu shu*, very inaccurately translated by the Six Scripts, which may be briefly noticed:—

1. 指事 *chih shih*, indicative or self-explanatory characters. This is a very small class, including only the simplest numerals and a few others such as 上 "above" and 下 "below."

2. 象形 *hsiang hsing*, pictographic characters.

3. 形聲 *hsing shēng* or 諧聲 *hsieh shēng*, phonetic compounds.

4. 會意 *huì i*, suggestive compounds based on a natural association of ideas. To this class alone can the term "ideographs" be properly applied.

5. 轉注 *chuan chu*. The meaning of this name has been much disputed, some saying that it means "turned round"; e.g., 目 *mu* "eye" is now written 目. Others understand it as comprising a few groups of characters nearly related in sense, each character consisting of an element common to the group, together with a specific and detachable part; e.g., 老, 考 and 耆, all of which have the meaning "old." This class is concerned only with peculiarities in the use of characters.

6. 假借 *chia chieh*, borrowed characters, that is, characters adopted for different words simply because of the identity of sound. The period of "borrowed characters" did not last very long, though traces of it are thought to be seen in the habit of writing several characters, especially those for certain plants and animals, indifferently with or without their radicals.

Styles of Writing.—In the earliest inscriptions (Shang dynasty, 18th century B.C.), the so-called 古文 *ku-wen* or "ancient figures," all the above-mentioned forms occur. None are wholly

pictorial, with one or two unimportant exceptions. In the following specimen only the last character is unmistakably pictorial: This is read: 申作寶鼎 "Shên made [this] precious *ting*." In 1903 a large number of inscribed bone fragments were excavated in the north of China, which have furnished

a list of nearly 2,500 separate characters, of which not more than about 600 have been so far identified. They appear to be responses given by professional soothsayers to private individuals who came to them seeking the aid of divination in the affairs of their daily life. The bones were ancient but some at least of the inscriptions have been forged. It is difficult to fix their date with much exactitude. The script, though less archaic than that of the earlier bronzes, is of an exceedingly free and irregular type. Some attribute them to the Shang, or Yin dynasty (1766–1122 B.C.) in accord with Chinese tradition. Others think that they represent a mode of writing already obsolete at the time of their production, and retained of set purpose by the diviners from obscurantist motives, dating them about 500 years later, or only half a century before the birth of Confucius, long after the appearance of a new and more conventionalized form of writing, called in Chinese 篆 *chuan*, which is commonly rendered by the word Seal, for the reason that many ages afterwards it was generally adopted for use on seals. Under the Chou dynasty, as well as the two succeeding it, the meaning of the word was not "seal," but "sinuous curves," as made in writing. This epoch possibly marks the first introduction into China of the brush in place of the bamboo or wooden pencil with frayed end which was used with some kind of colouring matter or varnish, and the introduction of a supple implement like the brush at the very time when the forms of characters were fast becoming crystallized and fixed, would account for a great revolution in the style of writing. Authentic specimens of the 大篆 *ta chuan*, older or Greater Seal writing, are exceedingly rare. But it is generally believed that the inscriptions on the famous stone drums, now at Peking, date from the reign of King Hsian, and they may therefore with practical certainty be cited as examples of the Greater Seal in its original form. These "drums," really ten roughly chiselled

mountain boulders, were discovered in the early part of the 7th century, lying half buried in the ground near Fêng-hsiang Fu in the province of Shensi. On them are engraved ten odes, a complete ode being cut on each drum, celebrating an imperial hunting and fishing expedition in that part of the country. Great strides had been made in this writing towards symmetry, compactness and conventionalism. The vogue of the Greater Seal appears to have lasted until the reign of the First Emperor, 221–210 B.C. (see *History*), when a further modification took place. For many centuries China had been split up into a number of practically independent States, and this circumstance seems to have led to considerable variations in the styles of writing. Having unified the empire, the First Emperor proceeded, on the advice of his minister Li Ssü, to standardize its script by ordaining that only the style in use in his own State of Ch'in should henceforward be employed throughout China. This new style of writing was the Greater Seal characters in the form they had assumed after several centuries of evolution, with numerous abbreviations and modifications. It was afterwards known as the 小篆 *hsiao chuan*, or Lesser Seal, and is familiar from the *Shuo Wen* dictionary (see *Literature*). Though a decided improvement on what had gone before, something less cumbrous was soon felt to be necessary by the clerks who had to supply the immense quantity of written reports demanded by the First Emperor. Thus a simpler and more artistic form of writing was in use, though not universally, not long after the decree abolishing the Greater Seal. This 隸書 *li shu*, or "official script," as it is called, shows a great advance on the Seal character. It is perhaps likely to have been directly evolved from the Greater Seal. It differs from the modern character only in minor details. The Lesser Seal was evidently obsolete at the time of the compilation of the *Shuo Wen*, about 100 years after the Christian era. The Greater Seal and still earlier forms of writing had fallen into utter oblivion before the Han dynasty was 50 years old.

Out of the "official script" two other forms were soon developed, viz., the 草書 *ts'ao shu*, or "grass character" which so curtails the usual strokes as to be comparable to a species of shorthand, requiring special study, and the 行書 *hsing shu* or running hand, used in ordinary correspondence. Some form of grass character is mentioned as in use as early as 200 B.C. or thereabouts, though how nearly it approximated to the modern grass hand it is hard to say; the running hand seems to have come several centuries later. The final standardization of Chinese writing was due to the great calligraphist Wang Hsi-chih of the 4th century, who gave currency to the graceful style of character known as 楷書 *k'ai shu*, sometimes referred to as the "clerkly hand." When block-printing was invented some centuries later, the characters were cut on this model, which still survives at the present day. The script of China has remained practically unchanged ever since. The manuscript rolls of the T'ang and preceding dynasties, discovered by Sir Aurel Stein in Turkestan, show a style of writing not only clear and legible but remarkably modern in appearance.

Grammar.—No set of rules governing the mutual relations of words has ever been formulated by the Chinese, apparently because the need of such rules has never been felt. The most that native writers have done is to draw a distinction between 實字 and 虛字 "full" and "empty words," respectively, the former being subdivided into 活字 "living words" or verbs, and 死字 "dead words" or noun-substantives. By "empty words" particles are meant, though sometimes the expression is loosely applied to abstract terms, including verbs. The above meagre classification is their nearest approach to a conception of grammar in our sense. Every Chinese character is an indivisible unit, representing a sound and standing for a root-idea. Being free from inflection or agglutination of any kind it is incapable of indicating in itself either gender, number or case, voice, mood, tense or person. No Chinese character can be definitely regarded as being any particular part of speech or possessing any particular

function absolutely, apart from the general tenor of its context. Thus, taken singly, the character 上 conveys only the general idea "above" as opposed to "below." According to its place in the sentence and the requirements of common sense, it may be a noun meaning "upper person" (that is, a ruler); an adjective meaning "upper," "topmost" or "best"; an adverb meaning "above"; a preposition meaning "upon"; and finally a verb meaning "to mount upon," or "to go to." It would puzzle grammarians to determine the precise grammatical function of any of the words in the following sentence, with the exception of 何 (an interrogative, by the way, which here happens to mean "why" but in other contexts is equivalent to "how," "which" or "what"): 事何必古 "Affair why must ancient," or in more idiomatic English, "Why necessarily stick to the ways of the ancients in such matters?" Or take a proverbial saying like 少所見多所怪 which may be correctly rendered "The less a man has seen the more he has to wonder at." It is one thing, however, to translate it correctly, and another to explain how this translation can be inferred from the individual words, of which the bald equivalents might be given as: "Few what see, many what strange." To say that "strange" is the literal equivalent of 怪 does not mean that 怪 can be definitely classed as an adjective. On the other hand, it would be dangerous even to assert that the word here plays the part of an active verb, because it would be equally permissible to translate the above, "Many things are strange to one who has seen but little."

There are certain positions and collocations of words which tend to recur, but the number of qualifications and exceptions which will have to be added is so great as to render the rule itself valueless. 馬上 means "on a horse," 上馬 "to get on a horse." But it will not do to say that a preposition becomes a verb when placed before the substantive, as many other prepositions come before and not after the words they govern. If we meet such a phrase as 警寇, literally "warn rebels," we must not mentally label 警 as a verb and 寇 as a substantive, and say to ourselves that in Chinese the verb is followed immediately by its object. Otherwise, we might be tempted to translate, "to warn the rebels," whereas a little reflection would show us that the conjunction of "warning" and "rebels" naturally leads to the meaning "to warn (the populace or whoever it may be) *against* the rebels." Each particular passage is best interpreted on its own merits, by the logic of the context and the application of common sense. The beginner must accustom himself to look upon each character as a root-idea, not a definite part of speech.

The Book Language.—In the beginning, all characters doubtless represented spoken words, but there was no need to reproduce in writing the bisyllabic compounds of common speech because *chien* "to see," in its written form 見, could not possibly be confused with any other *chien*, and it was therefore unnecessary to go to the trouble of writing 看見 *k'an-chien* "look-see," as in colloquial. All superfluous particles or other words that could be dispensed with were ruthlessly cut away, and all the old classical works were composed in the tersest of language, far removed from the speech of the people. The passion for brevity and conciseness resulted often in such obscurity that detailed commentaries on the classics have always constituted an important branch of Chinese literature. After the introduction of the improved style of script, and when the mechanical means of writing had been simplified, literary diction became freer and more expansive, to some extent, but the classics were held in such veneration as to exercise the profoundest influence over all succeeding schools of writers, and the divorce between literature and popular speech became permanent. No book of any first-rate literary pretensions would be easily intelligible to any class of Chinese, educated or otherwise, if read aloud exactly as printed. The public reader of stories is obliged to translate, so to speak, into the colloquial of his audience as he goes along. There is no inherent reason why the conversation of every-day life should not be rendered into characters, as is done in foreign

handbooks for teaching elementary Chinese; one can only say that the Chinese do not think it worth while. There are a few words, indeed, which, though common enough in the mouths of genteel and vulgar alike, have positively no characters to represent them. On the other hand, there is a vast store of purely book words which would never be used or understood in conversation.

The book language is nice in its choice of words, and obeys special rules of construction. Of these, perhaps the most apparent is the carefully marked antithesis between characters in different clauses of a sentence, which results in a kind of parallelism of rhythmic balance. This parallelism is a noticeable feature in ordinary poetical composition, and may be well illustrated by the following four-line stanza: "白日依山盡 The bright sun completes its course behind the mountains; 黃河入海流 The yellow river flows away into the sea. 欲窮千里目 Would you command a prospect of a thousand li? 更上一層樓 Climb yet one storey higher." In the first line of this piece, every single character is balanced by a corresponding one in the second: 白 white by 黃 yellow, 日 sun by 河 river, and so on. In the 3rd and 4th lines, where more laxity is generally allowed, every word again has its counterpart, with the sole exception of 欲 "wish" and 更 "further." Some of the early Jesuit missionaries, men of great natural ability who steeped themselves in Oriental learning, have left very different opinions on record. Chinese appeared to be as admirable for the superabundant richness of its vocabulary as for the conciseness of its literary style. And among modern scholars there is a decided tendency to accept this view as embodying a great deal more truth than the other.

The Chinese language has to assimilate the vast stock of new terminology which closer contact with the West would necessarily carry with it, by the conjunction of two or more characters already existing; of this 昇降機 (rise-descend-machine) for "lift," and 議政國會 (discuss-govern-country-assembly) for "parliament" are examples. Even a metaphysical abstraction like the Absolute has been tentatively expressed by 絕對 (exclude-opposite); but in this case an equivalent was already existing in the Chinese language.

A drastic measure, strongly advocated in some quarters, is the entire abolition of all characters, to be replaced by their equivalent sounds in letters of the alphabet. Under this scheme 人 would figure as *jên* or *ren*, 馬 as *ma*, and so on. But the proposal has fallen extremely flat. The vocables are so few that only the colloquial, if even that, could possibly be transcribed in this manner. Any attempt to transliterate classical Chinese would result in a mere jumble of sounds, utterly unintelligible, even with the addition of tone-marks. There is another aspect of the case. The characters are a potent bond of union between the different parts of the country with their various dialects, and the script, in spite of certain disadvantages, has hitherto triumphantly adapted itself to the needs of civilized intercourse.

Giles, *A Chinese-English Dictionary* (2nd ed., 1910); B. Karlgren, *Sound and Symbol in Chinese* (1923).

CHINESE LITERATURE is especially remarkable (1) for its antiquity, coupled with an almost unbroken continuity down to the present day; (2) for the variety of subjects presented, and for the exhaustive treatment which not only each subject but also each subdivision has received, as well as for the colossal scale on which many literary monuments have been conceived and carried out; and (3) for the accuracy of many of its historical statements, so far as it has been possible to test them.

The Chinese usually divide their literature into four great groups. Under the first of these we find the Confucian Canon, together with lexicographical, philological, and other works dealing with the elucidation of words. Under the second, histories of various kinds, officially compiled, privately written, constitutional, etc.; also biography, chronography, catalogues, government, geog-

raphy and bibliography. Under the third, philosophy, religion, e.g., Buddhism; the arts and sciences, e.g., war, law, agriculture, medicine, astronomy, painting, music and archery; also a host of general works, monographs, and treatises on a number of topics, as well as encyclopaedias. The fourth class is confined to poetry and essays, poetical critiques and works dealing with the rhymes—what might, in other words, be called *belles lettres*.

Poetry.—Proceeding, with only partial reference to Chinese classification, we begin with the last of the above four classes. Among the oldest Chinese records in our possession are songs and ballads. The earliest were for ritual purposes in religious ceremonies, and may belong to about the ninth century B.C. These and later poems of the Chou period are collected in the *Shih Ching*, popularly known as the odes, which forms an important portion of the Confucian Canon. The odes treat of a variety of subjects of war and love, of eating and drinking and dancing, of the virtues and vices of rulers, and of the misery and happiness of the people. Many are for religious purposes, and others are satires, or love songs, or complaints of soldiers against their commander, or are for popular festivals.

Passing over the intervening centuries we come to the most glorious age of Chinese poetry, the T'ang dynasty. From the long string of names which have shed lustre upon it, the following, all of the first rank, may be mentioned. Mêng Hao-jan (A.D. 689–740) failed to succeed at the public competitive examinations and retired to the mountains, where he led the life of a recluse. Later he obtained an official post; but he was of a timid disposition, and once when the emperor, attracted by his fame, came to visit him, he hid himself under the bed. His hiding-place was revealed by Wang Wei, a brother poet. The latter (A.D. 699–759), in addition to being a first-rank poet, was also a landscape-painter of great distinction. He was further a firm believer in Buddhism; and after losing his wife and mother, he turned his mountain home into a Buddhist monastery. Of all poets, no one has made his name more widely known than Li Po, or Li T'ai-po (A.D. 705–762), popularly known as the Banished Angel, so heavenly were the poems he dashed off, often under the influence of wine. Although a genial companion and at times in high favour at court, he was of a roving disposition, and a strain of melancholy, of unsatisfied longing, runs through his verses. Tu Fu (A.D. 712–770) is generally ranked with Li Po, the two being jointly spoken of as the chief poets of their age. Tu Fu, like the latter, led a chequered and wandering life. Po Chü-i (A.D. 772–846) held several high official posts, but found time for a considerable output of some of the finest poetry in the language. His poems were collected by imperial command and engraved upon tablets of stone.

The poets of the Sung dynasty (A.D. 960–1260) were many and varied in style; but their work, much of it of the very highest order, was more formal and precise. Life seemed to be taken more seriously than under the gay and pleasure-loving T'ang. The long list of Sung poets includes such names as Ssü-ma Kuang, Ou-yang Hsiu and Wang An-shih. A still more familiar name in popular estimation is that of Su Tung-p'o (A.D. 1031–1101), known partly for his romantic career, but still more as a brilliant poet and writer of fascinating essays.

The Mongols (A.D. 1260–1368), who succeeded the Sungs, and the Mings who followed the Sungs and bring us down to the year 1644, helped, especially the Mings, to swell the volume of Chinese verse, but without reaching the high level of the two great periods above mentioned. Then came the Manchu dynasty, of which the same tale must be told, in spite of two highly cultured emperors, K'ang Hsi and Ch'ien Lung, both of them poets and one of them author of a collection containing no fewer than 33,950 pieces, the majority of which are but four-line stanzas of little literary value.

The chief moods of the Chinese poet are a pure delight in the varying phenomena of nature, and a boundless sympathy with the woes and sufferings of humanity. Erotic poetry is not absent, but it is not proportionate to the great body of Chinese verse. In his love for hill and stream, which he peoples with genii, and for tree and flower, which he endows with sentient souls, the Chinese poet is seen at his best. His views of life are deeply tinged with melan-

choly and often loaded with an overwhelming sadness "at the doubtful doom of humankind." In his lighter moods he draws inspiration, and in his darker moods consolation, from the wine-cup. The present day, with its use of the colloquial for literary purposes and its break with old conventions, is witnessing many interesting new schools of poetry, some of them strongly Chinese, others with Western prototypes.

History.—The oldest of Chinese histories is a series of ancient documents now passing under a collective title as *Shu Ching* and popularly known as the canon or book of history. Some of its documents are genuine remains of the Chou dynasty and a few are possibly even of earlier date, but others are fabrications of later times. The work opens with an account of the legendary emperors Yao, Shun and Yü, and continues down into the 8th century B.C. The next step brings us to Confucius. Among his other literary labours, the great sage undertook to produce the annals of Lu, his native State, basing them on the officially kept chronicle of that principality. The work is known as the *Ch'un Ch'iu* (i.e., the Spring and Autumn), Annals. It consists of a varying number of brief entries under each year of the reign of each successive ruler of Lu which scarcely make possible the reconstruction in any detail of the age they profess to record. The *Tso Chuan*, a so-called commentary on the Ch'un Ch'iu, in reality is only in part that. It is mainly an independent history of another one of the feudal states of the Chou period.

Historiography took its next great step under Ssü-ma Ch'ien (145–87 B.C.), the son of an hereditary grand astrologer who was also an eager student of history and the actual planner of the great work so successfully carried out after his death. By the time he was ten years of age, Ssü-ma Ch'ien was already well advanced with his studies, and at 20 he set forth on a round of travel which carried him to all parts of the empire. Entering the public service, he was employed upon a mission of inspection to the newly conquered regions of Ssuch'uan and Yünnan. In 110 B.C. his father died, and he stepped into the post of grand astrologer. After devoting some time and energy to the reform of the calendar, he took up the work which had been begun by his father and which was ultimately given to the world as the *Shih Chi*, or historical record. This was arranged under five great headings, viz., (1) Annals of Imperial Reigns, (2) Chronological Tables, (3) Monographs, (4) Annals of Vassal Princes and (5) Biographies. The historical record begins with the so-called Yellow Emperor, a shadowy and probably mythical figure, and continues down into the Han dynasty. Ssü-ma Ch'ien's great work has been accepted as the model for all subsequent dynastic histories, of which 26 have now been published. As a rule each dynasty found its historian in the dynasty which supplanted it; and as a group the dynastic histories are notable for the fairness with which the conquerors have dealt with the vanquished, accepting without demur such records of their predecessors as were available from official sources. The output of history, however, does not begin and end with the voluminous records above referred to. History has been a favourite study with the Chinese, and innumerable histories of a non-official character, long and short, complete and partial, political and constitutional, have been showered from age to age upon the Chinese reading world. One of the chief of these is the *T'ung Chien*, or mirror of history, so called because "to view antiquity as though in a mirror is an aid in the administration of government." It was the work of a statesman of the 11th century, whose name, by a coincidence, was Ssü-ma Kuang. It embraces a period from the 4th century B.C. down to A.D. 960. It is written in a picturesque style, but the arrangement was found to be unsuited to the systematic study of history. Accordingly, it was subjected to revision, and was to a great extent reconstructed under the direction of Chu Hsi (A.D. 1130–1200), the famous philosopher.

In regard to biography, the student is by no means limited to the dynastic histories. Many hundreds of biographies have been written and huge biographical collections have been compiled and published.

Geography and Travel.—There is a considerable volume of Chinese literature which comes under this head, but if we exclude

relatively few accounts of foreign countries, nothing in the way of general geography had been produced prior to the arrival of the Jesuit Fathers at the close of the 16th century. Up to that period geography meant the topography of the Chinese empire, and of topographical records there is a very large and valuable collection. Most of the prefectures and departments have their individual topographies, compiled with great fullness from records and from tradition. The buildings, bridges, monuments of archaeological interests, etc., in each district are all carefully inserted, side by side with biographical and other local details. The Chinese have been fond of travel, and hosts of travellers have published notices, more or less extensive, of the different parts of the empire, and even of adjacent nations. With Buddhism came the desire to see the country which was the home of the faith, and several important pilgrimages were undertaken with a view to bringing back images and sacred writings to China. Chief among these pilgrims, from the standpoint of the records which they left, were Fa Hsien, whose travels covered the years A.D. 399-414, and Hsüan Tsang, who was away from China from A.D. 629 to 645.

Philosophy.—In philosophy China has almost as long a history as the Occident. A brief survey can only name a few outstanding figures and indicate some of the main trends of thought. As has been hinted (*see CHINA, HISTORY*), the Chou dynasty witnessed the beginning of philosophical speculation and before its close the main schools of native thought had begun to take form. Most of the founders served the State as officials and the problem common to them all was one of government. The empire was broken into many warring States, injustice and oppression were rife, and an awakening conscience sought a remedy. The early philosophers, then, were concerned chiefly with social and ethical questions. They were interested only incidentally, if at all, in theories of knowledge or of a future life. What in time came to be the dominant school found its great formulator in Confucius (6th and 5th centuries B.C.). Born in the feudal State of Lu in what is now Shantung, for part of his life he was in office. His standards were too high to permit him to remain permanently in official position, and during most of his career he was a teacher, for years travelling from place to place hoping that a prince would accept his services on his own exacting terms. He believed social salvation to lie chiefly in a return to the best of the past. This he interpreted as emphasis on the cultivation of morality in the governing classes (for he believed that political problems were fundamentally ethical and that the example of the rulers determined the character of the people), on bringing into the service of the State the men of highest integrity and education, the perpetuation of the ceremonies, religious, social and political, of antiquity, and on loyalty to the chief social relations, particularly those of the family. He declined to discuss the future life and was reserved about the supernatural, but he had a profound belief that directing the universe was a righteous Being before whom man should stand in awe and conscious dependence.

Mencius, who lived in the second half of the 4th century, revered Confucius but placed greater emphasis upon the innate goodness of human nature and, as a natural corollary to it, enunciated the duty of princes to listen to the voice of the people and the right of the people to revolt against injustice in high places. Hsün Tzu, of the 3rd century B.C., also claiming to be of the spiritual lineage of Confucius, held man to be bad by nature but capable of improvement through proper ethical standards and regulation by himself and the State. He denied all belief in the supernatural and in spirits, and depersonalized the ruling element in the universe by describing it as unvarying law.

A second school of thought, commonly called Taoism and also beginning in the Chou dynasty, has as its basic classic the *Tao Tê Ching*. The authorship of this is usually ascribed, although on decidedly dubious grounds, to a shadowy Lao Tzu, said to have been an older contemporary of Confucius. The *Tao Tê Ching* held up as ideal conformity to the way of nature (the Tao). Conformity to the way of nature, it maintained, involved the absence of regulations and of the artificialities of civilization. In a rough way this early Taoism corresponded to the philosophical anarchism of the West. Chuang Tzu, of the 4th and 3rd centuries B.C., was of

the same school, and by his vivid style did much to give it currency—and prepared the way for its eventual degradation.

Mo Ti, of the 4th and 5th centuries B.C., was very influential. He held that all institutions should be judged by their ability to promote human welfare, and on that ground condemned, among other things, music and elaborate funerals. He also believed that ruling the universe is a Being whose dominant characteristic is love, and that love of man for man should be the basic principle of human conduct. He was followed by two schools, one of which developed his principle of utility into a logical method based on empiricism, and the other emphasized the religious side of his teaching.

Yang Chu, also of the 4th century B.C., was an ethical egoist, who would have each man seek happiness for himself in ways dictated by prudence, but with no care for the happiness of others.

The Legalists, who flourished chiefly in the fourth and third centuries B.C., emphasized, as their name indicates, well-devised laws, adjusted to the needs of the time as a means of bringing order into the disturbed society of their day.

With the Han dynasty, Confucianism was made the established philosophy of the State, and free speculation tended to die. Mohism disappeared, although not without influencing Confucianism; and Taoism, while at times popular at court, degenerated into a search for the elixir of life and a means of effecting the transmutation of metals. At least one semi-independent thinker of importance, Wang Ch'ung (A.D. 27-97), appeared, teaching, among other things, that man might be either good or bad by nature, and declaring spirits and miracles to be hallucinations. With the entrance of Buddhism in the latter part of the Han dynasty and the rapid spread of the new faith in the next few centuries, new elements were brought into Chinese philosophy. Descriptions of Buddhism and of Buddhist thought are given elsewhere and need not be repeated here. Buddhism greatly influenced Taoism, but for several centuries orthodox Confucianism was but little modified by it. During the Sung dynasty, however, Confucian scholars came to grips with some of the fundamental issues raised by Buddhism and several interpretations contended for the mastery. That finally accepted by the State had as its greatest exponent Chu Hsi (A.D. 1130-1200), who by his lucid pen aided its triumph. Chu Hsi made Confucianism an orderly philosophical system, which, while professedly grounded solidly on the ancient classics, showed distinctly the influence of Buddhism, and had a cosmology that would have seemed strange to many of the Chou period.

Until the beginning of the 20th century Chu Hsi dominated official scholarship. Here and there was an influential rebel, the most prominent being Wang Yang-ming (A.D. 1472-1528), who, after attempting to arrive at knowledge in the way commended by the orthodox (the investigation of the outward world), had an experience of enlightenment resembling that of the Buddhist, and henceforth sought by looking within his own mind and heart to understand the universe. Some modern radical scholars, moreover, regard a small group in the Manchu dynasty as having prepared the way for the intellectual revolution of to-day. During the last few years, with the breakdown of the older structure of government and its support of orthodoxy, and with the New Tide or Renaissance movement, interest in philosophical speculation has again awakened. Many schools of thought are represented.

Arts and Sciences.—Not much, relatively speaking, has been written by the Chinese on military strategy or tactics. However, one very remarkable work has come down to us from the 6th century B.C., the *Art of War*, by Sun Wu.

In spite of the high place accorded to farmers, who rank second only to officials and before artisans and traders, and in spite of the assiduity with which agriculture has been practised in all ages, most of what agricultural literature the Chinese possess may be said to belong to modern times. Until the present century the standard work was the *Nung Cheng Ch'üan Shu*, compiled by Hsü Kuang-ch'i (1562-1634). It is in 60 sections, the first three of which are devoted to classical references. Then follow two sections on the division of land, six on the processes of husbandry, nine on hydraulics, four on agricultural implements, six on plant-

ing, six on rearing silkworms, four on trees, one on keeping and breeding animals, one on food and 18 on provision against a time of scarcity.

From Chou times China has had medical works of many kinds. Until the coming of Western medical science, in the whole range of Chinese medical literature there was nothing which could approach the *Pên Ts'ao*, or *Materia Medica*, sometimes called the Herbal. This was compiled by Li Shih-chen, who completed his task in 1578 after 26 years' labour. No fewer than 1,892 species of drugs, animal, vegetable and mineral, are dealt with, arranged under 62 classes in 16 divisions.

Mathematics and astronomy have both been written about fairly extensively. Foreign influence has been potent in both these fields.

The practice of divination is of ancient date, more so than even the *I Ching*, or canon of changes. The *I Ching* was originally deduced from eight diagrams made up of broken and unbroken lines (thus, ☯, ☯, ☯, ☯, etc.). It is attributed, mistakenly, to Wên Wang, whose son founded the Chou dynasty. To it many of the greatest Chinese philosophers devoted much thought and it has been widely used by many different kinds of diviners. Numbers of other methods have also been adopted and have yielded a considerable bulk of literature. In like manner, geomancy is a subject on which many volumes have been written; and the same applies to palmistry, physiognomy, and alchemy.

Calligraphy, in the eyes of the Chinese, is just as much a fine art as painting, but the latter occupies the larger space in Chinese literature and forms the subject of extensive works. One of the most important of these is the *Hsüan Ho Hua P'u*, the author of which is unknown. It contains information concerning 231 painters and the titles of 6,192 of their pictures, all in the imperial collection during the reign period *Hsüan Ho* (A.D. 1119-1126) from which the title is derived.

The literature of music does not go back to a remote period. The canon of music, which was formerly included in the Confucian Canon, has been lost for many centuries. The works now available, exclusive of entries in the dynastic histories, are not older than the 9th century A.D. There are a vast number of works, many of them exhaustive, on such topics as archaeology, seals (engraved), numismatics, pottery, ink (the mis-called "Indian"), mirrors, precious stones, tea, wine, chess, wit and humour, cookery, etc. Reprints of miscellaneous books and pamphlets in a uniform edition, the whole forming a "library," have long been a favourite means of disseminating information. In a similar manner it has been customary for relatives or friends, sometimes for the trade, to publish the "complete works" of important and often of unimportant writers, usually soon after death.

Novels and Plays.—Although novels were formerly not regarded as an integral part of literature proper, it was generally conceded that some might be profitably studied, if for no other reason than their style. Their first marked development was in the Mongol dynasty. The *San Kuo Chih*, an historical romance based upon the period of disruption at the close of the 2nd century A.D., is a delightful book, packed with episodes of battle, heroism, self-sacrifice, skilful strategy and all that goes to make up a stirring picture of strenuous times. Its author cannot be named for certain; it probably belongs to the 13th century. From the 13th century the growth of the novel was continuous; and finally, in the 17th century, a point was reached which is not likely soon to be surpassed. The *Hung Lou Meng*, the author of which took pains, for political reasons, to conceal his identity, is a creation of a very high order. Its plot is intricate and original, and the *dénouement* startlingly tragic.

Simultaneously with the appearance of the novel, stage-plays seem to have come into existence in China. In the earliest known ages there were set dances by trained performers, to the accompaniment of music and singing; and something of the kind, more or less ornate as regards the setting, had long been associated with solemn and festive occasions. However, not until the days of the Mongol rule, A.D. 1260-1368, can the drama proper be said to have taken root and flourished in Chinese soil. There is an excellent collection of 100 plays of the Mongol dynasty, published in

1615. There is also a large collection, issued in 1845 and in the years following.

Dictionaries and Encyclopaedias.—The *Erh Ya*, commonly classed as a dictionary, is referred by native scholars generally to the 12th century B.C., but its true date is undetermined and is undoubtedly many centuries later. With the *Shuo Wên*, or explanation of written words, we begin the long list of lexicographical works which constitute such a notable feature in Chinese literature. A scholar named Hsü Shên, who died about A.D. 120, made an effort to bring together and analyze all the characters it was possible to gather from the written language as it existed in his own day. He then proceeded to arrange these characters (about 10,000 in all) on a system, by radicals, which would enable a student to find a given word without having to search through the whole book. Passing over a long series of dictionaries and vocabularies which appeared at various dates, some constructed on Hsü Shên's plan, with modifications and improvements, and others, known as phonetic dictionaries, arranged under the finals according to the tones, we come to the great standard lexicon produced under the auspices, and now bearing the name of the Emperor K'ang Hsi, A.D. 1662-1723. The total number of characters given therein amounts to over 44,000, grouped no longer under the 540 radicals of Hsü Shên but under the much more manageable number of 214, as already used in earlier dictionaries. Further, as the groups of characters would now be more than four times as large as in the *Shuo Wên*, they were subdivided under each radical according to the number of strokes in the other or phonetic part of the character.

Considering the long unbroken series of years during which Chinese literature has, in spite of many losses, been steadily gaining in bulk, it is not astonishing to find that classical, historical, mythological and other allusions to personages or events of past times have also grown out of all proportion to the brain capacity even of the most brilliant student. Designed especially to meet this difficulty, there are several well-known handbooks, elementary and advanced, which trace such allusions to their source and provide full and lucid explanations. In their desire to bring together condensed, yet precise, information on a large variety of subjects, the Chinese may be said to have invented encyclopaedias. They differ, however, from Western encyclopaedias in being made up, not of articles especially composed for the purpose, but of extracts of existing works. Though not the earliest work of this kind, the *T'ai P'ing Yü Lan* is the first of any great importance. It was produced toward the close of the 10th century A.D., under the direct supervision of the emperor. Its total number of sections is 1,000, arranged under 55 headings. Other encyclopaedias, differing in scope and in plan, appeared from time to time. The largest ever compiled was the *Yung Lo Ta Tien*, under the orders of the third emperor of the Ming dynasty. Yung Lo's object was to collect all that had ever been written on the Confucian Canon, history, philosophy and the arts and sciences. The resulting work was too huge to be printed, for it ran to 22,937 books, and only three copies were made. Of these, two were destroyed on the fall of the Ming dynasty and the third, with the exception of a few odd volumes, at the time of the Boxer outbreak. The *T'u Shu Chi Ch'êng* was planned, and to a great extent made ready, under instructions from the Emperor K'ang Hsi and was finally brought out by his successor, Yung Cheng, 1723-36.

Recent Developments.—The intellectual revolution which is one of the accompaniments of the impact of the West upon China has resulted in a vast flood of literature. Most of it is ephemeral: newspapers by the thousand, magazines by the score, placards and pamphlets. Much of it is in the form of text-books on modern subjects issued by such publishing houses as the Commercial Press. Some is of a more original nature, such as a history of philosophy by Hu Shih, books by Liang Ch'í-ch'ao, and Liang Siu-ming's *The Civilizations of the East and the West and Their Philosophies*. All these are symptomatic of the greatest intellectual ferment that China has known for centuries. Most of the modern literature is in the *pei hua*, a purified form of the mandarin. All accepted standards of literature as well as of other phases of human thought and activity are being challenged and the end is not yet in sight.

At the conclusion of this brief survey of Chinese literature, it may well be asked how such an enormous and ever-increasing mass has been handed down from generation to generation. When the Chinese began to write in a literary sense, as opposed to mere scratchings on bones, they traced their characters on slips of bamboo and tablets of wood with a bamboo pencil, frayed at one end to carry an ink of lacquer made from tree sap. About 200 B.C. a brush of hair was substituted for the bamboo pencil; after which, silk was called into requisition as an appropriate vehicle in connection with the more delicate brush. Under the later Han dynasty paper was developed, the traditional date of its invention being A.D. 105. Printing was preceded by rubbings from inscriptions, printed silk, stencils, seals and stamps. The earliest extant examples of true printing, by means of engraved blocks of wood, date from A.D. 770 and are from Japan, but these were preceded by earlier steps in China for the purpose of reproducing the Buddhist Scriptures. Moveable types were invented in the 11th century, but the prevailing method even to-day is by engraved blocks of wood, one block for each two pages of text.

CHINESE MUSIC. Music played a great part in the origins of ancient Chinese civilization, the pitch-pipe of the normal pitch (called Huang-chung) was the basis of the Chinese system of measures, of the calendar and of their astronomical calculations.

A Musical System.—According to tradition, the emperor Huang-ti (c. 2697 B.C.) sent his minister Ling-lun to the Kun-lun mountains in north-west China to cut a pitch pipe from a species of bamboo which gave the note Huang-chung. Eleven other notes were derived from this note by the following process: a third part of the nine-inch pipe Huang-chung was cut off, thus producing a second pipe, Lin-chung, which was six inches long ($9 \times \frac{2}{3}$) and gave the fifth. The second pipe was divided into three parts, and one of the third parts was added to it (8 in. or $6 \times \frac{2}{3}$); this gave the descending fourth (Tai-tsu) from the second pipe, and so on. This was the origin of the 12 Chinese pitch pipes; Huang-chung (C), Ta-lu (C#), Tai-tsu (D), Chia-chung (D#), Ku-hsi (E), Chung-lu (F), Jui-pin (F#), Lin-chung (G), I-tse (G#), Nan-lu (A), Wu-i (A#), and Ying-chung (B). The Chinese system of fifths is first mentioned in the work *Lu-Tsu-Chun-Chiu*, which dates from the 3rd century B.C.—about the time when the Pythagorean musical system was made known in Greece by the pupils of Pythagoras.

As the circle of fifths could not be closed owing to the (Pythagorean) comma, the Chinese made a number of attempts in the course of the ages to divide the octave into 60 notes (King-fang, c. 40 B.C.), 360 notes (Chien-lo-chih, c. A.D. 430), 18 notes (Tsai-yuan-ting, c. A.D. 1180), and 12 notes (Ho-cheng-tien, c. A.D. 420 and Wang-po, c. A.D. 958), equal and unequal temperament respectively. The old system of fifths still continued however to be the prevailing system. Finally, Prince Chu-tsai-yu, in 1595, a century earlier than Andreas Werkmeister (1691) in Europe, fixed the twelve pitch-pipes in equal temperament; in order to obtain the nearest semitone he divided the length of a pitch-pipe by 1.0594631 or $\sqrt[12]{2}$ and its diameter by 1.0292857 or $\sqrt[12]{2}$. The mathematical and physical basis was confirmed by experiment by the Belgian authority on acoustics, V. Ch. Mahillon.

The ancient Chinese scale has five tones: Kung (C), Shang (D), Chiao (E), Chih (G) and Yu (A). Later, under the Chou dynasty (1122-255 B.C.), two further notes, Pien-chih (F#) and Pien-kung (B) were added.

Each note of this scale of five or seven notes can be used as the primary note of a scale, and this gives five or seven modes, just as in Greek music we have the Doric, the Phrygian mode, etc. As each of these five or seven modes can be transposed in twelve ways, there are 60 or 84 keys in Chinese music. (X.)

Musical Practice.—The ancient theory and the classical music of past centuries are connected almost exclusively with the rites and ceremonies of the temples of worship and of the court. One of the old literary classics, the *Li Ki* or *Book of Rites*, contains many allusions to music; and one whole section (said to be a later interpolation) is devoted wholly to music in its ethical, ritual and symbolic aspects. Until a few decades ago the Imperial Ministry of Rites included a bureau of music, but the function of this office seems to have been entirely a matter of ceremonial tradition, and to have had no connection with the practice of music in its popular forms. The performance of ritual music was continued in certain places up to most recent times with a scrupulous adherence to tradition. The solemn celebration of the highest office of the Confucian worship is accompanied by a traditional orchestra of 44 pieces. Taoist temples are content with about six instruments. In the Confucian solemn rite the Emperor himself was supposed to be the chief celebrant. The pentatonic, non-harmonic music for this celebration has often been reproduced in European notation in the books on Chinese music, particularly the solemn march to which the imperial worshipper proceeded to the door of the temple and the concluding monodic hymn to Confucius (Ta tsai K'ung tsen) in which all the instruments and voices took part.

Music outside the temples is more popular in character and has probably been subjected to more frequent changes in style; although even here the tenacious conservative instincts of the race have handed down a more archaic type of music to the present day than is known in the occidental countries. The practice of this music by individuals, particularly by amateurs of high social status for their own aesthetic satisfaction is not so widespread in China as in the West. Home or household music seems to have been more highly developed in Japan than in China. There is, in China, no well organized class of professional music teachers. Most musicians acquire their art in a purely empirical way,

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART
CHINESE GONG AND STICK, A MUSICAL PERCUSSION INSTRUMENT NOW USED CHIEFLY IN THE THEATRE

although there is a considerable body of books containing the notations of tunes for various instruments. This notation is not a staff notation, but a tablature system, that is, a series of signs or symbols for the individual tones, frets or finger positions. Vocal music has an important place in the temples and still more in the theatre. Apart from this it is not cultivated as an art co-ordinate with instrumental music to the same extent as in Western nations, although the singing of songs and ballads is not uncommon.

Musical Instruments.—The number of instruments used by

the Chinese is comparatively large. Moule lists and describes not fewer than 130. Many of them are, to be sure, mere toys or signal instruments of no great musical importance. They are used by mountebanks at fairs or markets, and by hawkers or beggars. European writers about Chinese instruments devote much space to the description of the ancient classic instruments used in temple worship, many of which have long since gone out of common use. They are largely percussion instruments, including many forms of highly ornamented drums (*Ying ku*, 應鼓; *po fu*, 搏附; *pang ku*, 梆鼓), sonorous stones single (*t'e k'ing* 特磬) or arranged in chimes (*pien k'in* 編磬) or bronze bells used in the same manner (*po chung* 銅鍾; *pien chung* 編鍾). The *k'in* 琴 is a narrow hollow box 3 to 4 ft. in length, with slightly convex upper surface. It has five, or in more modern instruments, seven silk strings plucked with the fingers, and was still used until fairly recent times for refined artistic music. Its Japanese counterpart is the *koto*. A larger instrument constructed on the same principle, but having in earlier times as many as 50 strings, later only about 25, is the *se*, rarely used except in ceremonies. The ancient instruments were classified by the older theory according as they produced the sound of stone, metal, silk, bamboo, wood, skin, gourd and earth. The most important instruments still in use are the two-stringed fiddle, *hu k'in*, 胡琴; the four-stringed moon guitar, *y'ueh k'in*, 月琴; the four-stringed, pear-shaped, balloon guitar, *pi p'a*, 琵琶; the three-stringed guitar with a very long neck, *san hsien*, 三絃; a first cousin of the Japanese *samisen*. Of the flute type are the straight (direct) flute *hsiao* 簫; and the transverse flute *ti*, 笛. Reed instruments are represented by the gentle *kuan tzu* 管子, a straight bamboo tube, 8 to 10 in. long, with a rice straw serving as a double reed or oboe mouthpiece; and the shrill, *so na* 鎖呐, a double reed instrument with a conical wooden body ending in a metal "bell," often called the Chinese clarinet. The *sheng* 笙 consists of a lacquered wooden body (formerly a gourd or calabash), about the shape and size of a tea cup, and a mouthpiece through which the player inhales the air. On the body are grouped 13 to 17 speaking pipes, slender bamboo tubes each provided with a thin, free reed of metal. Each tube has a hole below the reed and the pipe speaks only when the hole is stopped by the player's finger. The *yang k'in*, 洋琴, or foreign psaltery, consists of a trapezoidal sound box about 2 ft. in width over which are usually stretched 14 to 20 double, triple or quadruple sets of metal strings which are played by striking them with two light bamboo rods.

Modern percussion instruments, used chiefly in the theatre, include the large gong (*lo* 鑼), cymbals (*po* 鈸), a flat circular drum, struck with a pair of light sticks (*pang ku* 梆鼓) and sharply resonant wooden blocks or castanets (*pe pan* 拍板). Before the revolution of 1911-12, professional musicians had no high social standing. Those who played in the theatre commanded more respect than the players in funeral or wedding processions. Courtesans and beggars who played and sang, and ballad singers were of the lowest rank. The Chinese theatre makes copious use of music, the drama being practically a music drama. A relatively very small part of the play is given over to unaccompanied spoken dialogue. The recitative portions are either punctuated by the

percussion instruments or are invested with a continuous rhythmic accompaniment of these instruments which often drown out the actor-singer's voice. The lyric portions of the performance are accompanied by the fiddles, guitars, flutes or pipes. The protagonist selects the tunes from among a large number of well-known conventional strains or motives, said to be very old. The instrumentalists accompany in unison, although, since they play without

CHINESE DULCIMER (YANG CH'IN), HAVING 16 SETS OF STRINGS, 4 IN EACH SET, AND PLAYED WITH TWO BAMBOO BEATERS

written music, embellishments and variations are produced *ad libitum*, and there are at times instances of the use of double notes and traces of an embryo type of contrapuntal invention. The Chinese ideal of good vocal performance, particularly for the male actors, requires a high, forced falsetto tone production.

All of this music, as well as the popular music of funeral and wedding processions and of street songs is, like the sacred music, distinctly pentatonic. But where, as in the popular orchestra or solo performance, the art of improvisation and embellishment has free play, the larger intervals of the five-tone scale are frequently filled out in runs and figures, as a careful analysis of phonograph records (Erich Fischer) has shown. But even here the importance of the pentatonic skeleton or foundation is beyond doubt and is easily sensed by the European hearer. Since the revolution the influence of Western music has become more marked.

CHINESE PAINTING. The first thing to be said about Chinese painting is that very little is known of its actual achievements. We have indeed ample records of the lives and works of innumerable painters, from the first centuries of our era onwards, and a mass of criticism. Chinese paintings also exist in vast quantities. But it must be realized that of genuine, or probably genuine, works of the great masters of the best periods, very few indeed remain. It is impossible to doubt, from the evidence of what has survived, and from literary records, that Chinese painting, with its majestic and continuous tradition of more than 1,500 years, is one of the greatest schools of painting that the world has seen. But we are quite without the means of comparing Chinese painting as a whole with the paintings of Italy, or any other European school, the successive masterpieces of which are known and accessible to every student.

It is true that during the 20th century the almost complete ignorance which prevailed on the subject till the end of the 19th century has been greatly lessened. Important discoveries have been made, and it is impossible to predict what may yet be discovered. The fundamental difficulties, however, of the study of Chinese painting are likely to remain; the extreme rarity, namely, of certain and documented works, on which an accurate conception of the greater masters' style can be based. The practice of repeating famous designs with variations, of copying ancient works, which has prevailed in all ages, makes it possible to have a general idea of the styles of certain periods and certain masters.

But immense and repeated destruction accounts for the rarity of ancient pictures in China itself. In Japan collections have been made, centuries ago, and religiously preserved; and these paintings form the best foundation for study, though in many cases the traditional attributions have been abandoned by modern criticism.

General Characteristics.—Painting is the pre-eminent art of China. It is right that the art of any nation should be judged by a world standard, not merely from a national point of view. In spite of all differences and peculiarities, Chinese painting takes its place with the other pictorial arts of the world, for there is a fundamental affinity between all successful works of art.

Painting, for the Chinese, is a branch of handwriting. Both for writing and painting a brush is used; and to acquire a fine hand in writing demands a mastery in manipulating the brush and modulating its strokes such as few European painters attain. Ink is the favourite medium; but Chinese ink is a wonderful substance, capable of an immense range and an extraordinary beauty of tone. Many Chinese masterpieces are in monochrome. Coloured paintings are either light-coloured or full-coloured; but the ink-drawing remains almost always the foundation of the design. Fresco-painting, technically a different method from the fresco-painting of Europe (see Church's *Chemistry of Paints and Painting*, p. 307, 1915), was largely practised—and probably the grandest art of China was in this form—but the frescoes of the finest period seem all to have been destroyed. The great mass of Chinese pictures, however, are paintings on silk or, less commonly, absorbent paper, the pigments being water-colours or body-colours (see R. Petrucci, *Encyclopédie de la Peinture Chinoise*, 1918, a translation of a well-known treatise illustrated with woodcuts called the *Mustard Seed Garden*. See also Ferguson's *Chinese Painting*). Paintings are usually in the form of hanging pictures or of horizontal scrolls, in both cases normally kept rolled up. The latter form involves a mode of composition peculiar to Chinese art, though imitated by the Japanese. These paintings, often of great length, are unrolled bit by bit and enjoyed as a reader enjoys reading a manuscript. A succession of pictures is presented, though the composition is continuous. Thus, in the case of landscape, for which this form has been used with most felicity, one seems to be actually passing through the country depicted. Other forms are the framed picture and the small album picture; screens also were employed for painting.

Chinese technique admits of no correction. The artist closely observes and stores his observations in his memory. He conceives his design, and having completed the mental image of what he intends to paint, he transfers it swiftly and with sure strokes to the silk. The communication through the sensitive and powerful strokes of the brush of something personal and unique must, in such an art, count for much in the spectator's appreciation. The qualities prized by the Chinese in a small ink-painting of bamboos, a favourite subject alike with beginners and masters, are those prized in a piece of fine handwriting, only there is added a keen appreciation of the simultaneous seizure of life and natural character in the subject. In the *Mustard Seed Garden* treatise cited above, it is said that in a master's work "the idea is present even where the brush has not passed." And this emphasis on the value of suggestion, of reserves and silences, is important to notice, because no other art has understood, like the Chinese, how to make empty space a potent factor in the design. It may be that Chinese painting relies too much on suggestion, presuming in the spectator a sensibility and a fineness of organization which are found but in choice societies; on the other hand it avoids that laborious accumulation of unessential phenomena which in European art has proved the death of so many pictures by accomplished hands. A certain slightness, comparatively speaking, is inevitable in Chinese paintings, partly because of the water-colour medium, partly because suggestion is preferred to statement, partly because so many of the artists were amateurs and not professionals. It is remarkable, however, how solid and structural a Chinese landscape can be. The greater painters gave much thought and pains to elaborating a convention by which the sense of shape and mass can be given to rock forms, for instance, without losing directness, and vitality of brush stroke, the sense of handwriting. Each successful con-

vention was preserved, handed down and imitated. Mountains could be painted in the manner of this old master or of that. And the Chinese, with their passion for codification, have carefully tabulated all these various methods. The painter's art is also saturated with literary associations. Certain flowers and certain birds, for instance, are painted together because their association is consecrated by a classic poem. Many of the painters were poets; some, like Wang Wei, equally distinguished in both arts. But it is less the direct illustration of a poem or story that is normally aimed at, than the evocation of a mood similar to that expressed in the poem.

When we turn to the subject-matter of Chinese painting, we are struck by the early appearance of landscape art and its actual predominance. Landscape is accounted the most important of subjects because it includes man and all living things; the whole is greater than the part. Man does not play the central and heroic part that he plays in the art of Europe, for which the nude human form is the most significant and expressive of motives. Flowers are quite as important as figures. This difference in the fundamental conception of life and the universe makes itself felt in design. Instead of the symmetry which contemplation of the human body has made the basis of Western composition, the Chinese prefer the principle of balance. They contemplated trees and saw that they were unsymmetrical but perfectly poised. Where in Europe we have Christian themes, in China we have Buddhist themes; instead of the stories of classic mythology we have the stories of Taoist legend and the fairy tale. Genre-painting (*q.v.*) is as common as in the West, though portraiture is perhaps less common. But always the life of the world outside man,—the life of animals, birds and plants—plays a much larger part than in Western art. The life of action counts for less, and the contemplative life for more.

HISTORY

Early Periods.—From literary references we can infer that painting was practised in China several centuries at least before Christ, chiefly in the form of portraiture. It is not till we come to the Han dynasty, that we have any more tangible evidence, though there exist some rude designs in red on jade which may be a thousand years earlier. Designs on lacquer of the 1st century A.D., found in Korea by Mr. Umehara, and in Chinese Turkistan by Sir Aurel Stein; some rough paintings on tiles (Eumorfopoulos collection), and other decorations; outline drawings on vases of rather later date, give some hint of what painting in the Han period was like. We see that a Chinese type of decorative design, animated by movement in the forms, was already matured. The incised stone friezes of the period are clearly translations of paintings, and these give an idea of the character of pictorial design and the range of subject—scenes from history and legend, ceremonies, dances, mythical creatures, and all the fairy world of Taoism.

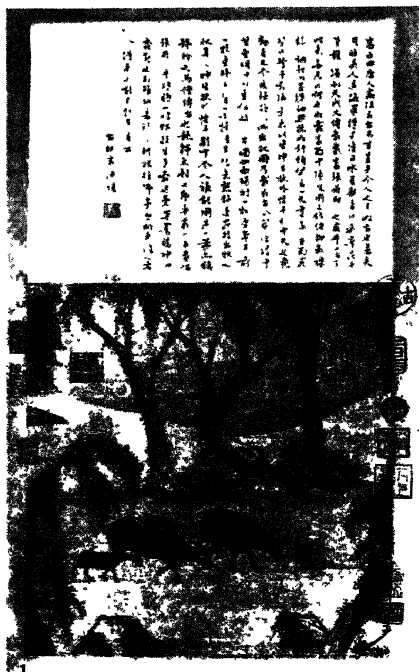

In the 4th century, however, flourished an artist who ranks among China's most famous masters: Ku K'ai-chih. There exist two rolls attributed to him: one, *The Admonitions of the Instructress in the Palace*, is in the British Museum; the other, illustrating a poem on a river nymph, is in the Freer collection at Washington. These paintings are by different hands. The one in the Freer collection is altogether drier in handling, and may be a Sung copy. The British Museum roll is of a marvellous subtlety and distinction; the line is intimately expressive. Its actual date is disputed, but it is generally thought to be, if not an original, a T'ang copy. In any case there is no doubt that both of these paintings represent the design of the Chin dynasty (A.D. 265–420). They are, therefore, extremely precious documents, and their value is increased by the fact that while the British Museum roll depicts scenes of court life, with all the details of dress and accessories of singular refinement, the Freer roll, with its dragon chariot and floating fairies, gives the imaginative or fanciful side of the art of the period. In both cases the landscape element is quite primitive. The landscape introduced into the London painting is indeed in strong contrast with the consummate grace and expressiveness of the tall and slender figures,

SIX CHARACTERISTIC PAINTINGS, 4TH TO 14TH CENTURY

1. Chinese herdsman, a painting of the mid-12th century, Sung period. 2. A man on a water-buffalo attributed to Li T'ang (c. 1100), of the Northern Sung school. 3. Landscape with bridge and willows, by Ma Yuan, a landscape painter of the late 12th and early 13th century. His work shows the vigor of the Northern Sung school combined with delicacy and sensitiveness. 4. Detail, from

"Ladies Beating and Preparing Silk," a genre painting attributed to the artist-emperor, Hui Tsung (1082-1135), Sung dynasty. It probably preserves a T'ang design. 5. Portrait of a Buddhist priest, a Chinese fresco of the 14th century. 6. "Harmonious Family Life," part of "The Admonitions of the Instructress in the Palace," attributed to Ku K'ai-chih (4th century), one of China's earliest painters

and the air of a mature and fine civilization which they seem to breathe. Far from being primitive, the figure-drawing seems to belong to the close of a tradition rather than its beginning; and we may conjecture behind it the ruder, masculine style of Han gradually subtilized and transformed in the direction of elegance and charm. Ku K'ai-chih famed especially for his portraits, painted all kinds of subjects, including Buddhist themes. But if we may take these two pictures attributed to him as typical of the period, we find no trace of Indian influence in them.

Of about the 6th century are some of the earliest wall paintings in the rock temples at Tun-huang, on China's western frontier (see Pelliot, *Grottes de Touen-houang*, vol. iv.), full of animated movement, containing figures of the same slender and elegant type as those in the Ku K'ai-chih roll. But these are provincial in manner.

It was in the 6th century that the famous six canons of Hsieh Ho, himself a painter, were formulated. The exact meaning of the first and most important of these has been disputed, but it is clear that the emphasis is laid on creative inspiration, conceived not as a personal gift, but as the spirit of the cosmos entering into the artist and enabling him to produce in his forms the movement of life.

The legends of the great masters tell, not of the deceptive appearance of reality in their paintings, but of their being so informed with passionate life that they assumed material existence and motion. The emphasis on movement is significant. Even in decorative designs the forms seem to move and flow.

The T'ang Dynasty (A.D. 618-905).—In the 7th century the empire, after a period of division, was consolidated under the great T'ang dynasty, which lasted for 300 years. This was undoubtedly the period of China's grandest art. It is true that almost all the painting of the time has perished; but all the available evidence confirms the testimony of the Chinese historians and critics to the greatness of the T'ang masters. Some fragments of a painting of a spring festival, found by Sir Aurel Stein in 1914 at Turfan, and some other paintings found in the same locality by the Otani expedition, are precious relics of early T'ang art, for they show us something of the pictorial style of the early 8th century. Here we find the new T'ang ideal of feminine beauty: a more massive form, compared with the slender elegance of preceding periods; a full, rounded face, with hair heaped around and above the head, and an air of smiling health. Precisely the same types and the same pictorial motives are found in the few pictures surviving from this period in Japan. And it is from the early painting of Japan, closely modelled on Chinese prototypes, that we can most safely infer the great style of T'ang. This kind of painting is mostly Buddhist, and the grandest T'ang works were of Buddhist inspiration. Supreme among them, according to all testimony, were the works of Wu Tao-tzū, acknowledged to be the greatest of all Chinese painters.

China, during this epoch, was open to foreign influences as she has never been since. Her empire expanded westward; her suzerainty extended as far as the Caspian. Envoys and tribute-bearers were constantly coming or going; there was a great interest in foreign ways, dresses and customs; Indians, Persians, Turks and Syrians met in the capital, which was truly a world centre. But the influence of greatest moment was Buddhism, now accepted with fervour. Great numbers of Indian monks, some of them doubtless artists, were settled in China. Chinese pilgrims journeyed to India and brought back sacred manuscripts and images. But Chinese art, strong in its own traditions, was able to assimilate the Indian formulae and create a Buddhist art of extraordinary splendour. Among the earliest of the T'ang masters may be mentioned Wei-ch'ih I-sêng, who came from Khotan to China about 630. A copy of a picture of Vaisravana by this artist is in the Freer collection at Washington; and his style is perhaps to be discerned in a remarkable roll in Mr. Berenson's collection. Yen Li-pên (born c. 600), was famous for his portraits of national worthies, foreign envoys and Buddhist pictures. We know his work only through copies. With Wu Tao-tzū, T'ang painting underwent a transformation. His early style was fine and delicate; later, it became broad and of amazing

power. He painted over 300 Buddhist frescoes, as well as paintings of all kinds of subjects on silk. All have perished. One or two of his designs have been preserved by being engraved on stone, and some paintings and drawings are extant which may be copies from his work. The majestic fresco *Three Bodhisattvas*, given to the British Museum by Mr. Eumorfopoulos, dating probably from the 12th century, presumably preserves the T'ang tradition, and from it we may infer the yet grander and more magnificent creations of Wu Tao-tzū and his followers. All records agree in emphasizing the overwhelming power of his creations and also the almost sculptural character of his figures. Of actual and authenticated work by a known T'ang artist we have only five portraits of priests (much damaged) painted about 800 by Li Chên and preserved in Japan. These are in a contained and rather austere style. But our chief documents for T'ang Buddhist painting are the pictures recovered from Tun-huang, on the western frontier of China, by Sir Aurel Stein and Prof. Pelliot. These are now in the British Museum, at Delhi and in Paris. A certain number are dated, with dates of the 9th and 10th centuries. Those which are in Chinese style may be taken to reflect the central tradition of Buddhist painting, though in a more or less provincial form. Of much the same character is a large Buddhist picture of the 9th century in the Boston Museum.

The Tun-huang pictures are largely devoted to the cult of Amitabha Buddha, who presides over the Western Paradise, and of his spiritual son Avalokitesvara, or Kuan-yin, the genius of Compassion, who in later times assumes a feminine form. There are many pictures of the Paradise, in which we see a host of blessed beings presided over by a Buddha (usually, but not always, Amitabha) gathered round a sacred concert, where a dancer performs to music on a terrace raised above the lotus-lake. Some of these complex compositions, containing a great number of figures, are remarkable for the harmonious serenity of the design—there is no confusion or awkwardness in the arrangement—and the varied beauty of the colouring. Other votive pictures portray the great Bodhisattvas, especially Kuan-yin, or scenes from the Buddha legend. In the former case, the forms, draperies and ornaments are closely modelled on Indian prototypes; in the latter, types, dress and architecture are purely Chinese. From the small scenes sometimes painted at the sides of the large pictures we get a hint of the secular style of the period both in figure and landscape. The figures of donors, which are also fairly frequent, give us contemporary costume. Though mostly the work of artisans rather than artists, the value of these paintings as documents is very great, and a few are of real beauty as works of art.

In this era landscape became important as an independent art. The character of Chinese landscape is seen in the word for landscape, *shan-sui* (山水), mountain and water. Li Ssü-hsün (b. 651) was the first eminent painter who devoted himself mainly to landscape. He painted in greens and blues, with gold outline. None of his works exist, but copies preserve the characteristics of his style. His son, Li Chao-tao, developed this technique. A small picture in the Boston Museum, ascribed to him but probably of later date, gives a good idea of this "miniature" kind of landscape-painting. A very different tradition in landscape was founded by Wang Wei (b. 699), who was equally famous as a poet. He matured a style of ink-painting, in which the landscape became the counterpart of an emotion, more subjective and more "impressionist" in method than the work of Li Ssü-hsün and his school. Copies exist (one is in the British Museum, and an earlier one in the Freer collection) of a famous roll by Wang Wei, *Scenery of the Wang Ch'uan*. The painting was engraved on stone when it began to decay. Rubbings have been published by Dr. B. Laufer in *Ostasiatische Zeitschrift* (April 1912).

Ts'ao Pa and his greater pupil, Han Kan, were especially famous for their paintings of horses. Han Kan found endless subjects in the fine horses sent as tribute from Central Asia. He worked in the 8th century for the emperor Ming Huang. A contemporary, Han Huang, painted buffaloes and rustic scenes. The splendidly modelled pottery figures of horses and camels found in T'ang tombs give us a clue to the vigour and breadth

of the animal painting of these masters, whose original work has perished.

Admirable *genre* pictures and scenes from court life were also painted in this era. Chou Fang is known by versions (one in China and one in a New York private collection) of his *Listeners to Music*, a design in which the Chinese genius for eloquent spacing is conspicuous. The beautiful picture in the Boston museum of *Ladies Beating and Preparing Silk* probably preserves a T'ang design.

The Five Dynasties (A.D. 900-960).—In this short period a great many artists are recorded, of whom Hsü Hsi was famous as a flower-painter and Chou Wên-chü for his pictures of women. Still more celebrated was Huang Ch'uan, who painted landscape, birds, flowers, etc., and who is said to have started what is called the "boneless method"; i.e., painting without a drawn outline.

The Sung Period (A.D. 960-1260).—Under the emperors of the Sung dynasty China was re-united. The emperor Hui Tsung was himself a painter and a great collector. In his reign the Academy of Painting became very prominent and attracted artists from all parts. A certain realism was inculcated, but in style a fastidious simplicity was to be aimed at. The small album-painting of a bird in a bough in the Eumorfopoulos collection, and similar paintings in famous albums in Japan, some of which are attributed to Hui Tsung, illustrate the ideals of the time. Flower-painting, hardly existent in the T'ang period, was now a favourite theme, and some painters, like Wên T'ung, specialized in ink-painting of the bamboo. Of the flower-painters Chao Ch'ang was the most celebrated. The most eminent master in landscape of Northern Sung was Kuo Hsi, who wrote an essay on landscape, partly translated by Waley (*Chinese Painting*, pp. 189-194). Mi Fei invented a new style in landscape, without outline and with boldly brushed-in wooded peaks rising above rain and mist. His style is preserved in many pictures, though again few or none are likely to be actually by his hand. Chao Ta-nien painted autumn and winter scenes; Fan K'uan was famous for his snow-scenes.

But the most famous name in the art of Northern Sung is Li Lung-mien (c. 1040-1106). Much of his work consisted of copies from earlier masters. He had a reverential passion for tradition. At first he painted horses, but soon abandoned such subjects for Buddhist themes. Rarely using colour, he drew with a delicate, nervous line. Copies of his works are numerous, and a few originals have been reproduced in the *Kokka*. He is revered by the Chinese as a perfect type of Chinese culture; judged purely as an artist, he would not have so great a fame.

In 1127 the Tatars occupied northern China. The emperor Hui Tsung was taken prisoner and died in exile. Hang-chow became the new capital of what is known as Southern Sung. The changed temper of the times is reflected in the art of a people no longer greatly interested in external events which they were helpless to transform. The passion for romantic solitudes, for soaring peaks and plunging torrents, which had always haunted certain minds, eager to escape from the pressure of official life and ceremonious routine, became a mastering inspiration. The Zen sect of Buddhism, now dominant, with its reliance on intuition, its contempt for all outward forms, replaced the votive picture of single or assembled Bodhisattvas, glowing with colour and gold, by pictures of Arhats in intense contemplation, or by swift ink-sketches of Zen saints; even a poising bird or blossoming spray could become in this mode of thought as "religious" a theme as the glorified Buddha. The emphasis was all on the interior mind. This temper, to which Taoist love of freedom and fluidity contributed much, gives a peculiar poetic character to the art of Southern Sung. Some there were, like Li Sung-nien, who kept to the older traditions and painted scenes from history and legend, and sets of pictures on weaving and agriculture. But the genius of the age is seen rather in Li T'ang (to whom are attributed a roll in a Japanese collection and a beautiful small picture in the Boston Museum), and still more in his famous pupils, Hsia Kuei and Ma Yüan. Owing to the enthusiasm with which the landscapes of this school were collected in Japan, we are able to judge of its productions from concrete examples. Though this school

soon fell out of favour in China, it represents to Europe Chinese landscape at its finest; synthetic in conception, impassioned in execution, it unites simplicity with grandeur. Hills and high places had always been regarded with reverence as the abode of spirits. We find no counterpart to the feeling of aversion or disgust which the Alps inspired in Europeans down to so late a period. And though the Chinese have always been an agricultural people, it is not the relation of toiling man to the fruitful earth which inspires their typical landscape art. It is a more cosmic inspiration; a feeling of affinity between the human spirit and the energies of the elements,—the winds, the mists, the soaring peaks, the plunging torrents. Technically, Chinese landscape design differs from European. The high horizon precludes the need for uniting sky and ground, divided by the natural horizon of sight, by means of vertical lines and masses. The eye passes from the foreground, so often a source of trial and difficulty to the European painter, to the central motive of the picture, usually a mountain form.

The Yüan or Mongol Period (A.D. 1260-1368).—In this comparatively short period there was a tendency to go back to the style of ancient masters. Chao Mêng-fu is perhaps the most famous painter of the time. Countless pictures of horses now in Western collections are attributed to him, few of them with any probability. He also painted landscapes and flowers. Another fine painter was Jên Jên-fa, of whom there is a good example in the Eumorfopoulos collection, and others in Japan. The four chief landscape masters were: Huang Kung-wang, Wang Mêng, Ni Tsan, and Wu Chên. The two latter led roaming lives and had nothing of the professional about them. Ni Tsan painted suggestions of landscape in ink, in a reticent, delicate manner. Wu Chên, known as the "Priest of the Plum-blossom," excelled in paintings of bamboos. Ch'ien Hsüan is a master whose name is very frequently forged on paintings; he painted birds, flowers, also figures. Wang Yo-shui was famous for flowers. Yen Hui is greatly admired in Japan for his pictures of Taoist sages, but is less known in China.

The Ming Dynasty (A.D. 1368-1644).—The art of the Ming period is characterized as a whole by a gradual fading out of the interior glow which under Buddhist and Taoist inspiration had suffused the creations of earlier periods. Concentrated in herself, China had no longer any stimulating contact with the world without; and her art became concerned rather with the beauty of material things than with the expression of the interior spirit. At the same time a reverential conservatism prescribed for the painter both subject and manner of treatment. The painters of this period are so numerous that only a few outstanding masters can be mentioned. The first Ming emperor re-established the Academy of Painting, with the aim of emulating the glories of Sung art. Gifted painters flocked to his court. Lin Liang painted ink-pictures of eagles, wild geese, flowers, etc., in a style of extraordinary breadth and power. A good example is in the British Museum, which also has a fine *Fairy and Phoenix* ascribed to Wu Wei, a master who strove to recapture something of the strong brush-work of Wu Tao-tzu. Very typical of early Ming art are the bird and flower pictures of Pien Ching-chao (Pien Wên-chin) and of Lü Chi, in which a certain solidity and a decorative richness of colour combine with powerful drawing in a large design. In landscape, Tai Chin, accounted one of the foremost Ming painters, led a new movement and had many followers. His style was broad and free, with little or no colour. Another school preferred minuteness of detail, with an ornamental use of colour, especially a rich blue. Of this school were Chou Ch'ên and T'ang Yin, who also excelled in figures.

Tung Ch'î-ch'ang (1554-1636), eminent as a critic as well as a painter and calligrapher, despised these "professionals" and their laborious technique. He is associated with the "Learned Man's Painting," in which refined taste and literary associations counted for much more than mere accomplishment. Tung Ch'î-ch'ang claimed that this style originated with Wang Wei in the 8th century, the founder of the Southern school. (In distinguishing the Northern and Southern schools, he tried to give these rather shadowy terms a geographical foundation which does not really

Painting, probably early Ming period, by an unknown artist—a typical landscape composition

exist.) The Southern school, adorned in the earlier part of this period by Shên Chou and Wên Chêng-ming, two much-admired masters, had by the close of the dynasty become triumphant and supreme. Among bird and flower painters of the 16th century, Chou Chih-mien may be mentioned as one of the most distinguished, though his work is rare.

The Ch'ing (Manchu) Dynasty (A.D. 1644-1911).—Painting in the 17th and 18th centuries is very largely devoted to landscape in the style of the Southern school, which in the later developments of the literary man's style becomes loose, slight, capricious and eccentric. Among gifted amateurs of the beginning of the dynasty, Chu Ta is much admired for his ink-sketches of flowers, rocks, etc. More important artists of the K'ang Hsi period are "the four Wangs," Wang Shih-min, Wang Chien, Wang Hui and Wang Yuan-ch'í.

Another great figure in the 17th century is Yün Shou-p'ing, also called Nan-t'ien, the most famous flower painter of the Ch'ing period. Wu Li, who was converted to Christianity and became known as Father Acunha, painted landscapes. The influence of the Jesuits was considerable for a time in China, but had no lasting effect on the arts. The Jesuit Giuseppe Castiglione was made to learn the Chinese style of painting under the name Lang Shih-ning. Chiao Ping-ch'eng, however, learnt something of European perspective and taught it to Lêng Mei and other artists. Chiao Ping-ch'eng's sets of pictures of agriculture and weaving were engraved in 1696. Shên Nan-pin went to Japan and stayed at Nagasaki (1731-33); his work had a very stimulating effect on the naturalistic movement in Japan. Apart from this naturalistic movement, the modern painting of China seems to show little new life, and though good painters flourished in the 19th century, they were mostly content with exercises in the various manners consecrated by the past.

CHINESE PAVILION, **TURKISH CRESCENT**, **TURKISH JINGLE**, or **JINGLING JOHNNY**, an instrument consisting of a pole about 6 ft. high terminating in a conical metal cap or pavilion, hung with small jingling bells and surmounted by a crescent and a star. The Turkish crescent, or "jingling Johnny," as it was familiarly called in the British army bands, was introduced by the Janissaries into western Europe, but it has fallen into disuse now, having been replaced by the *glockenspiel* or steel harmonica.

CHINESE SCULPTURE. The historical records about sculptural works in China do not begin until the Ch'in dynasty (221-206 B.C.); the earliest refer to the 12 colossal statues of "the giant barbarians" and the bell-frames in the shape of monsters "with stags' heads and dragons' bodies," which the great emperor Ch'in Shih Huang Ti ordered to be cast from the weapons of war collected throughout the kingdom. These enormous bronze statues which were placed before one of the imperial palaces near Hsien Yang, on the Wei river in Shensi, are mentioned by Lu Chia, an author who lived from the Ch'in to the Han dynasty, and by several later chroniclers such as Chang Heng (d. A.D. 139) who speaks of "the metal barbarians sitting in a row." At the end of the later Han dynasty Tung Chow melted "ten bronze men into small cash, also the bell-frames"; the two remaining ones he set up inside the Ch'ing Ming gate at Ch'angan but these were also lost during the 4th century, when a local ruler tried to remove them but found them too heavy for the muddy roads, the result being that one was melted down into cash, the other thrown into the river. Nothing, however, is known about the artistic character of these statues, but their well recorded history proves that they were considered extraordinary both for their motives and their size.

Ch'in Dynasty.—The only sculptures now remaining which possibly might be attributed to the Ch'in dynasty are some decorative animals in bronze. Most of these are of small size and placed on the lids of sacrificial vessels, but nevertheless with a well developed sculptural character. A larger example,—

sometimes ascribed to the Ch'in period—is a statuette, that represents a reclining bull (now in the possession of L. Wannick, Paris). It is said to have been found together with some bronze vessels, decorated in Ch'in style, at Li Yü in northern Shansi, but to judge by its style, it can hardly have been executed before the 6th century A.D. (Northern Wei dynasty). We illustrate it, however, as a particularly fine example of early Chinese animal sculpture.

Among other bronze animals which have been ascribed to the Ch'in period should be mentioned a large dragon or hydra with crested neck and flame-like wings at the shoulders and the loins, in the collection of A. Stoclet, Brussels. It is in marked contrast to the bull, fierce, fantastic, grotesque to the utmost without any connections with nature, and must, indeed, be earlier in date, though hardly of the Ch'in period. Other fantastic animals such as intertwining dragons or felines appear at the handles of some large bells in Ch'in style.

New efforts were evidently made in different directions during this short period which, in the field of art, was simply an introduction to the classic age of the Hans. The rigid ceremonial art of earlier times is gradually modified by a more direct and vivid interest in nature. The Chou art (1122-256 B.C.) was preeminently symbolic and geometrical. The art of the Ch'in and the Han periods aimed at the presentation of the actual rhythm of things, the inherent life and significance of the artistic forms.

The Han Dynasty.—Most of the Han monuments have evidently been destroyed; yet, to judge from those which remain as well as from minor plastic creations in bronze and clay, Chinese sculpture was at this early period much better fitted to treat animal motives than human shapes. It is only in the reliefs that the human figures reach an importance comparable to that of the animals, and these are, on the whole, more like paintings translated into stone than real sculptures. With the exception of the small tomb statuettes made as substitutes for real people, human representations are quite rare and artistically much inferior to the representations of animals. The Chinese have never considered the human figure an artistic motive in itself, but simply used it for expressing an action or a state of consciousness. They have taken greater interest in types, postures and motives of drapery than in the bodily form or the muscular organism. The case is quite different with the animal sculptures. They may adhere to certain types or formulae characteristic of the period to which they belong but their artistic importance depends mainly on the rendering of their organic form and vitality. The best among them are monumental creations, hardly inferior to animal sculptures of any other period or nation. The conventionalization, which is more or less preponderant during the early epochs, does not convey an element of immaterial abstraction but serves to accentuate the muscular organism, the energy of movement, the monumentality of the form, all that makes the animals great and convincing as works of art.

Bronze, Clay and Stone Work of the Han.—Among the great number of wild and domestic animals represented in bronze, clay and stone during the Han period we may choose as examples some bears executed in bronze. The majority of these bears are quite small, intended to serve as feet for sacrificial vessels, but there are also some of a larger size which have the character of free standing sculptures. The two best are in the Gardner museum in Boston. These are represented in a squatting posture, stretching their heads forward with a friendly roar. The modelling of the limbs is not carried very far, yet it is sufficient to awake an impression of suppleness and force. The artist has not been afraid of exaggerations in the characterization of the lumpy forms or the telling postures. The heavy weight of the body supported by the broadly placed forepaws, the elastic power of the enormous legs, the softness of the bulky paws and the long nose which seems to form a direct continuation of the ears, are rendered with a power of conviction and a sense of monumental unity that are rarely found in later animal sculptures.

It should also be noticed that in their representations of animals the Chinese have quite often combined two or more into a group. They have composed them in the most intricate positions and

built up groups which satisfy the highest requirements of plastic art. Most of these groups are on a relatively small scale, but they are nevertheless truly monumental. The finest results are achieved in groups of fighting animals, because the bodies are here represented in their highest tension, in the full development of their muscular effort, and so closely interlaced that they complete each other perfectly in the expression of the plastic idea. The same is also true of some of the animals which are composed into an architectural unity with monuments such as the tomb pillars in Szechuan (which will be mentioned below).

Tomb Statuettes of the Han.—The greatest variety of animal types may however be found among the clay statuettes made for the tombs. The material was most easily handled and thus invited all sorts of individual variations, and as these clay sculptures were executed as substitutes for living animals, which in earlier times followed their dead masters into their tombs, it was natural that they should be made as lifelike as possible. The majority are domestic animals such as horses, sheep, dogs, pigs, hens and ducks in various sizes, the smallest hardly more than two or three inches high, the largest measuring a foot or more. They were usually executed in clay moulds but sometimes modelled by hand, and the best among them have retained a spontaneous freshness and vivacity which make them very entertaining. Proportions and shapes are treated with a great deal of freedom. The dogs have enormous heads, the horses have necks which curve like high arches, and the pigs have snouts like bowsprits, yet the exaggerations serve simply to accentuate the typical features of the various animals.

Besides the animals there are human *ming ch'i*, or tomb statuettes, made as substitutes for living people, such as servants, and wives who formerly were buried alive with the husbands. Most common amongst these statuettes from the Han period are the slender ladies in long robes with wide sleeves reminding one of the Japanese kimonos. They stand usually in very quiet postures simply with a slight inclination of the large round head, but occasionally we find them represented in a dancing movement, though with closed feet, swinging their bodies and their arms in a rhythmic fashion.

Stone Sculptures of the Han.—Stone sculptures on a large scale were, no doubt, also executed in steadily increasing numbers during the Han period, though comparatively few of them have been preserved. Among the earliest which can be approximately dated are the animals at the tomb of General Ho Ch'ü Ping, situated at the Wei river some 20 m. N.W. of Sianfu. They were discovered by Ségalen and Lartigue during their explorations in 1914 and more completely dug out by the latter in 1923. Lartigue has also published them in an article in the German magazine *Artibus Asiae* (1927) in which he presents some evidence for the supposition that these statues were executed about 117 B.C., the year of the death of the famous general. He thinks that the statues, which represent a horse standing over a fallen warrior, a reclining horse and a buffalo, were placed in front of the mound, and that their present quite irregular positions have been caused by the shifting of the mud. Besides these, complete sculptures may, however, be seen in the neighbourhood of the mound, a large block with a mythological figure, executed in relief, and fragments of some animal sculptures which seem to indicate that this large composition never was completely finished. It is difficult to appreciate the artistic importance of these large statues without seeing the originals, but if we may draw some conclusions from the reproductions, the sculptures are comparatively undeveloped from an artistic point of view. This is particularly true of the main statue, the horse standing over a fallen warrior. The composition is indeed significant but the formal treatment does not seem to do justice to the motive. The short-legged horse with an enormous head is more bulky than monumental, and the figure under its belly is simply a large block. Here is little of that intrinsic energy which is so prominent in some of the minor sculptures already mentioned. This impression is, however, to some extent counteracted by the reclining horse and the buffalo which, even if they are heavy and bulky with stumpy legs, reveal a very sensitive artistic treatment, particularly in

their expressive heads. Here one may discover a touch of that excellent animal psychology which is one of the greatest assets of Han art, a characterization which, to some extent, makes up for the shortcomings in other directions.

Sculpture Developed For the Dead.—Other stone sculptures from the beginning of the Han dynasty which might serve for comparison have not come to light, though it is more than probable that they have existed, because this tomb was

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART
SCULPTURE OF THE SUI PERIOD

hardly an isolated case, and broadly speaking sculpture in stone as well as in clay had its origin in the decoration and the arrangement of the tombs. It was for the dead rather than for the living that the Chinese developed their creative activity in the field of the plastic arts. As proof of this may be quoted not only the various classes of clay and stone sculptures mentioned above, but also numerous reliefs executed for the decoration of the "spirit chambers" of the tombs and the sculptural pillars placed in front of the mounds. These monuments marked as a rule the beginning of the "shen tao" (spirit path) which led up to the tomb and which in later times was farther and farther extended in a straight line from the mound towards the south. The interior of the tomb consisted often of two or more chambers (as also may be observed in contemporary Korean tombs), the first being a kind of ante-room called the "spirit chamber," where the soul of the deceased was supposed to dwell, while the coffin was placed, together with various vessels and other paraphernalia of bronze or clay, in the back room. The main decoration, be it in sculpture or painting, was concentrated in the ante-room where the walls often were covered with representations from ancient history and mythology or with illustrations with a moral import.

Tomb Pillars.—Quite a number of the decorative pillars which formed the gateway to the "spirit road" are known from central and western China, particularly the provinces of Honan, Shantung and Szechuan. They are usually constructed on a rectangular plan of large and well-fitted stone blocks reaching a total height of 15 to 18 feet. When completely preserved they consist of a moulded pedestal, a very broad shaft and a cornice over which the roof projects quite far. But the form varies somewhat in the different provinces; thus the pillars in Honan, of which the best known stand at T'eng Fung Hsien on Sung Shan, are very broad and provided with projecting buttresses. Otherwise they are quite simple without any particular development of the cornices and decorated with ornaments and figures in very low relief. The earliest of these Honan pillars is dated A.D. 118, the latest A.D. 175.

The pillars in Szechuan have usually no buttresses, but they are higher and characterized by a richer architectural composition; their upper parts, the cornices and friezes under the projecting roof are particularly well developed. We find here, reproduced in stone, the beam ends and brackets so characteristic of Chinese wooden architecture, and between these are sculptural decorations executed in high relief, sometimes almost in the round. These pillars are all from the later Han dynasty, but only one of them, the pillar of Fung Huan at Ch'ü Hsien, is dated by an inscription which contains the year A.D. 121.

Symbolic Decorations of the Han.—More important for their sculptural decorations are, however, two pillars in the same neighbourhood erected at the tomb of a man called Shen. On their shafts are representations of the symbols of the four directions; i.e., the red bird of the South, the white tiger of the East, the blue dragon of the West and the black tortoise of the North, animal representations which, with regard to energetic rhythm of line and grand decorative stylization, may be compared to the best works in bronze or clay known from this classic epoch. At the corners of the entablature are seated human figures which seem to carry the projecting beams on their shoulders, and, on the

2. Two tigers; stone relief from the same tomb
3. Statue of a guardian lion at entrance of the same tomb

middle of the south side, a kind of *t'ao t'ie* (glutton) appears between the beams. All these figures are executed practically in the round and most skilfully composed into the architectural scheme of the monument. The very high frieze is divided into two sections, of which the lower one is decorated with hunting scenes in quite low relief and the upper one with some larger figures in high relief. One may observe here men riding on stags, horse-like animals running along with the swiftness of the wind, and hunters who aim with their bows above their heads or grasp the passing leopard by its tail. Here is the same free-play with animal and human forms as may be observed on some of the inlaid bronze vessels or on the glazed Han urns with relief friezes. The motives seem to have some reference to the life beyond the tomb, though they represent this with a naturalness and an intensity of movement which make them appear like scenes from real life. The style reveals something of the same energy and nervous tension that characterizes the small bronze ornaments of this period, and it can hardly be explained without accepting an influence from west Asiatic sources, though the Chinese transformation of the west Asiatic tradition is more complete in the large stone sculptures than in most of the minor bronze ornaments.

Dramatic Expression of the Pillars.—The majority of the tomb pillars in Szechuan, of which at least a score were discovered by Ségalen and Lartigue during their exploration in 1914, show the above mentioned combination of friezes with flat reliefs and tri-dimensional representations of animals and human figures on the entablature. The motives vary, some being historical or legendary, others religious or mythological, but they are all more or less imbued with a dramatic expression, and executed in a form of high decorative beauty.

Much simpler than these are the pillars which stood at the entrance to the tomb of the Wu family at Ch'ia Hsiang in Shantung. They were erected about the year A.D. 147 and they are still in their original place, although the tomb-area has become a large pit, usually filled with water. The pillars are provided with buttresses and a small superior storey on the projecting roof, but their sculptural decoration consists simply of quite low reliefs representing dragons, tigers and birds, in decorative translation, besides legendary illustrations with a moral import, framed by geometrical ornaments of the same kind as may be found for instance on the mirrors of the Han period.

Reliefs of the Han.—The same kind of motive, executed in a strictly conventionalized linear style, appears also on the large stone slabs which used to be arranged along the walls of the ante-chamber in the tomb, but which are now transferred to a primitive little store-room where they stand without any kind of order. These reliefs from the Wu Liang Tzu tomb have become known all over the world through numerous series of rubbings taken of them since the 18th century, and reproduced in many Chinese and European publications. Two or three of the reliefs have found their way into Western collections, though it should be noticed that the majority of the stone reliefs, said to come from Wu Liang Tzu, are simply modern imitations, made on the basis of rubbings.

Legendary Motives.—Nothing is more entertaining than to follow, with the aid of Chavannes interpretations, the legendary motives represented in these reliefs and thus to learn something about classical Chinese examples of filial piety, matrimonial fidelity, the faithfulness of loyal citizens, the valour of great heroes, not to mention the quasi-historical traditions about the great Yü and Ch'in Shih Huang Ti or the mythological stories about the king of the East, Tung Wang Kung, and the queen of the West, Hsi Wang Mu. Very common motives in these reliefs are the long processions of riders and carriages and the rows of men on horseback escorting a carriage, which may be representations of the journey of the deceased to Hades.

The compositions are arranged in horizontal storeys, with single rows of figures, animals, trees, houses and the like, appearing as silhouettes against a neutral background. The artistic expression lies mainly in the contours, and in the engraved lines; the modelling of the forms is very slight. These reliefs may thus

hardly be called sculpture in the real sense of the word, but rather paintings or drawings translated into stone. We have reason to suppose that they were made after such patterns and reproduce popular wall paintings which existed in some contemporary palaces, a supposition which is supported by the poet Wang Yen Shou, who describes the wall paintings in the Ling Kuang palace executed about the middle of the 2nd century A.D. He mentions in his description mythological illustrations of the same kind as may be seen in the Wu Liang Tzu reliefs besides "many riotous damsels and turbulent lords, loyal knights, dutiful sons, mighty scholars, faithful wives, victors and vanquished, wise men and fools," motives which correspond more or less to those appearing on the stone reliefs from Wu Liang Tzu and other places in Shantung.

Bactrian Types.—It has been claimed that the proud horses of these reliefs were of Bactrian origin. This is possible but the Chinese sculptors were certainly less guided by observation of nature than by artistic models, be it in bronze, clay or textile. They have accepted and further developed a definite type of horse which probably existed in the art of the Hellenized west-Asiatic countries.

Less Hellenistic and more definitely Scytho-Iranian in character are the winding dragons and heraldically placed tigers which appear in one or two of these reliefs. They belong to the same great family of ornamental animals which we also met on the stone pillars in Szechuan, and may thus be said to form some additional proofs of the general acceptance of this kind of animal sculpture during the Han period.

Still more remarkable examples of the same stylistic current are the two lions which stood at the entrance to the tomb of the Wu family (at the sides of the above-mentioned pillars) but which are now more or less buried in the mud. The anatomical character of the only visible one is rather free. It is, indeed, no common lion but a descendant of those proud animals which stood at the royal palaces in Susa and Persepolis and whose artistic pedigree may be traced to Chaldean and Assyrian art. The form is supple, the body is thin, the whole animal is dominated by the broad curving neck which comes so far to the front that the head almost disappears and the neck continues in the enormous jaws. At the shoulders one may observe traces of small wings, though they have been practically worn off by time. Such a creation has hardly been shaped from nature. Even if single lions now and then were sent as tributes from western Asiatic nations to the Chinese emperor, these were hardly known by the people in the provinces, and as there were no other lions in China, we may well suppose that the inspiration for such animal representation was drawn from examples of Iranian art rather than from living models.

Animal Statues.—To the same group of animal statues from the end of the Han-epoch may also be assigned two winged tigers at the tomb of K'ao Yi at Ya Chou Fu in Szechuan, which have been published by Ségalen and Lartigue, and the enormous seated lion—which has served as a plinth for a pillar in the Okura museum in Tokyo. There are furthermore some minor animal statuettes of the same type but they hardly need detain us as they only verify what has already been said about the artistic style and derivation of these sculptures. Nor do we need to stop at the human figures executed in stone on a large scale, because their artistic importance is much inferior to that of the animals.

Animal Sculptures of the Six Dynasties Period.—During the centuries which followed the fall of the Eastern Han dynasty (A.D. 214) artistic activity in China lost some of its intensity. The times were restless, filled with war and political upheaval. The empire was again divided into several minor States, to begin with, the Three Kingdoms, Wu, Shu and Wei, and later on, after 223, into a northern and a southern half, the former being under the domination of the Tartars, among whom the Toba tribe came out the strongest and took the name of the Northern Wei dynasty, while the latter was ruled over by a number of short-lived native dynasties—Sung, Ch'i, Liang and Ch'en—which had their headquarters at Nanking. We know very little about the artistic activity during these times but it seems that the

stylistic traditions of the Han period remained in force also during the 3rd and 4th centuries of our era. Some tomb reliefs, mainly from Shantung, executed in a kind of coarser Han style, may well be of this transition period, and the same may be said of a number of minor plastic works in bronze and clay.

The general evolution can be followed most closely through the small tomb statuettes; they reflect the variations in taste and fashion better than the large stone sculptures. Among them are real *genre* figures represented in various occupations such as music-making, feeding the hens, or with children in their arms, and we may observe how the fashion is changed from the simple "kimono" to an elegantly draped mantle over a tightly-fitting undergarment and how the head-dress becomes higher and more decorative. These tomb statuettes and minor animals in terracotta originate mainly from Honan, whereas the larger stone sculptures of this same period are executed for the reigning dynasties in Nanking. These monuments which form one of the most important groups within the domain of Chinese sculpture, have been more or less identified and reproduced by various explorers.

The largest among these lions and chimaeras measure up to 10 or 12 ft. in length and may still be seen at their original places, but some smaller ones, 4 to 6 ft. long, have found their way to Western collections. They all represent winged, lion-like animals but it is possible to distinguish two main types, *i.e.*, the chimaeras, which are a kind of cross between dragons and lions, and the real lions which have wings on their shoulders but no feathers or scales on their bodies and no ornamental beard. The former seem to have been considered the nobler, because they were employed as guardians at the tombs of emperors, whereas the lions stood at the tombs of princes and dukes.

Early Chimaeras.—The earliest chimaera which can be dated stands at the tomb of Emperor Sung Wen Ti (d. 453). It is a colossal and, in spite of its dilapidation, still imposing animal, largely covered up by a heap of refuse, so that the statue had to be dug out whenever it was photographed. The upper part of the head is lost and the surface of the grey limestone is very much worn but it is still possible to see that the body as well as the legs have been covered by ornamental scales or feathers and that the animal had wings not only at the shoulders but also at the ears.

The second earliest in date of the chimaeras which still remain at their original sites is the one at the tomb of Emperor Ch'i Wu Ti (d. 493). The dimensions are somewhat smaller but the animal is more completely preserved. The long body has a more dragon-like character, the legs are comparatively short and the tail well developed. The most imposing part is, however, the enormous head with the open jaws from which the ornamental beard hangs like a long tongue. One may here observe three pairs of wings as well as feathers drawn in spirals over the whole body.

Sixth-century Chimaeras.—The same proud bearing characterizes the chimaera at the tomb of Emperor Liang Wu Ti (d. 549). The movement of the long and supple body is still better developed and it receives a most effective continuation in the enormous curve of the neck. The animal is moving forward in an ambling fashion; we feel its vigour and suppleness. The wings and the feathers are indicated in quite low relief or simply engraved.

This nobility and energy are carried still further in the two large chimaeras which now stand in the University Museum at Philadelphia. We have no information whence they come, but they illustrate a further evolution of the style of the chimaeras at the tomb of Emperor Liang Wu Ti, which would date them shortly after the middle of the 6th century. It is possible that they stood at the tomb of some of the emperors of the short Ch'en dynasty which followed after the Liang, such as Ch'en Wu Ti (d. 559) or Ch'en Wen Ti (d. 566). In comparison with these beasts, the earlier chimaeras appear almost like domestic animals. The fantastic wildness and the seething energy are here given free outlet. The legs are stretched, the bodies drawn, the head is wildly thrown backwards, the chest pushed forward into a large curve, and all these movements are accentuated by engraved lines

which give the impression of taut steel springs. Besides these large ones several minor chimaeras are known but none of them reaches the extraordinary expressiveness of the last-mentioned.

Winged Lions.—The largest of the winged lions still remain *in situ*, not far from Nanking; their weight and colossal dimensions have made their removal impossible, but some of them are so far decayed that, if nothing is done to protect them, they will soon disappear. The earliest and most important stand at

SCULPTURE OF THE NORTHERN WEI PERIOD

tombs of various members of the Liang family, *i.e.*, the brothers of the Emperor Wu Ti, Prince Hsiao Hsiu (d. 518), Prince Hsiao Tan (d. 522) and the cousin of the emperor, Duke Hsiao Ching (d. 523). Besides these, two or three pairs of large lions are in the same neighbourhood, at Yao Hua Men, to the east of Nanking, but they are later and artistically inferior. The anatomical difference between the lions and the chimaeras is, as already said, not very important. The former as well as the latter are feline animals with an enormous curving neck and wings, but they are not provided with scales or feathers, nor do they have any ornamental beard like the chimaeras, only a large tongue which hangs down from the open jaws over the projecting chest. They are all represented in an ambling posture, majestically walking or coming to a sudden standstill, when the fore-legs are strained and the hind-legs bent. The head is lifted high on the proudly curving neck, the forms are full, the limbs heavier than in the chimaeras. Their massiveness is at least as imposing as the concentration of power in their enormous limbs. Most eaten by frost and water are the lions at the tomb of Duke Hsiao Ching which is now covered by a watery rice field in which the lions sink up to their shoulders.

Lions of Hsiao Hsiu Tombs.—Better preserved and more completely visible are the two colossal lions at the tomb area of Hsiao Hsiu, now covered by the village Kan Yu Hsiang, and here remains one row of the other monuments which flanked the "spirit road," *i.e.*, two large tablets with inscriptions carried by tortoises and a fluted column on a plinth composed of winding dragons. This seems to be the earliest preserved "tomb alley" in China, an arrangement known from a great number of later tombs. The lions are of the same family as those already described, the fact that they have wings is in itself a proof of their dependence on Persian art. It should, however, be remembered that the Achaemenian and Sassanian animals were descendants of the Assyrian which must be regarded as the fore-fathers of all the greatest Asiatic and a good many European lion sculptures. To what extent the Chinese really knew such models is a question which cannot be discussed here; it is in any case evident that they transformed the foreign models quite freely, not to say fantastically, in harmony with their native traditions. These animal sculptures form stylistically a direct continuation of the plastic art of the Han period. Yet, they indicate that a new wave of Western influence reached China at this time on a more southern route than through the north-western nomads. These lion sculptures do not appear in the northern provinces which were dominated by the Tartars. They belong to the more southern provinces where the old Chinese civilization and the creative spirit of the "Han people" never were completely subdued by foreign elements.

Religious Sculpture of the Six Dynasties.—When Buddhist sculpture was introduced into China it had passed through a long evolution in India and Central Asia; the principal iconographic motives, symbols and attributes were all developed into definite forms; the Chinese took them over just as they took over Buddhist scriptures; and whatever modifications they may have

BUDDHAS OF THE EARLY 6TH CENTURY

1. Buddhist votive stela, dated A.D. 529. The interlacing dragons at the top are of the same character as those on the slabs raised at tombs in the Han period, but their fierceness and energy of movement reveal some influence from Sibero-Asiatic art
2. Seated Buddha in a niche at Yün Kang, Shan-si; early 6th century
3. Standing Buddha accompanied by two Bodhisattvas; early 6th century, Yün Kang, Shan-si

introduced concerned more the artistic interpretation than the motives themselves. It should never be forgotten that they were greater artists than any other people of the Far East, and when Buddhist art took root in China, the country was by no means devoid of sculptural monuments. There were (as we have previously seen) artistic traditions which could not be forgotten, only modified when applied to Buddhist motives. The Buddhas and Bodhisattvas were, of course, represented in human shapes but the artists could not enhance their significance by accentuating their physical organisms or their likeness to ordinary human beings, nor could they change their general shapes or postures if they wanted to be understood. The iconographic rules are indeed much more exacting in Buddhist than in Christian art, and the motives are more limited in their artistic scope.

Religious Symbolism.—The great majority of the Buddhist sculptures represent isolated figures, seated or standing in very quiet postures without any attempt at movement, except certain symbolic gestures. The heads are made according to quite definite types, somewhat changing with the periods and localities, but it is rare to meet heads with individual expression or portraitlike features. The bodies are as a rule entirely covered by long mantles or rich garments according to the rôle or meaning of the figure; they have hardly any importance of their own but serve simply as a substratum for the rich flow of the mantle folds which, particularly in the early sculptures, conceal the forms much more than they accentuate them. Even in figures which are represented almost nude, such as the guardians at the gate (*Dvarapalas*), the representation is not really naturalistic; their Herculean forms and muscular movements are altogether exaggerated and their significance is symbolic.

The earliest dated Buddhist sculptures in China, known to us, are small bronze statuettes of a greater historical than artistic importance. Some of them are provided with inscriptions which make it possible to fix their date, the earliest being of the years 437 and 444, whereas the earliest dated Buddha in stone is of the year 457. These small statuettes represent standing or seated Buddhas or Bodhisattvas against a leaf-shaped nimbus decorated with engraved flame-ornaments. The figures are mostly of a very moderate artistic importance recalling by their types and draperies the Graeco-Buddhist art of north India. The large nimbuses behind these small figures constitute, however, a feature which is not known in Gandahara sculpture.

Yün Kang Cave Temples.—The greatest *ensemble* of early Buddhist sculptures in China is to be found at the Yün Kang cave temples near Ta Tung Fu in Shansi where the Northern Wei dynasty had its capital until 494, when it was removed to Loyang in Honan. The work at these cave sculptures started about the middle of the 5th century and was continued towards the latter part of the 6th century. Amongst the rich material displayed at this place one may observe different stylistic currents, some originating from Central Asia and India, others more closely connected with earlier forms of Chinese art. Here are ornaments of a distinctly Iranian character, and architectural forms of the same type as on reliefs from Taxila and Peshawar, but also some decorative motives recalling the art of the Han period. Among the figures there are some curious examples which form a link with Central Asiatic art, e.g., the five-headed and six-armed god who sits on a large bird with a pearl in its beak. This is no doubt the Garuda-raja, the bird of Vishnu, which also may be seen in some paintings from Tun Huang. This and other Hindu divinities of a similar kind, which appear in the Buddhist pantheon at Yün Kang, testify that artistic influence from central and western Asia reached China in connection with the introduction of Buddhism.

Artistic Expression.—Most famous among the figures here are the colossal Buddhas and Bodhisattvas which, however, seem to us artistically least interesting. A certain conventional type and fold design have in these figures been enormously enlarged without any intensification of the rhythmic motives or the artistic expression. More artistic expression and beauty may be found in some other figures at Yün Kang which are less closely allied to Indian models and more imbued with the traditional

Chinese feeling for rhythmic lines and elegant form. The figures themselves are quite thin and flat, sometimes hardly modelled into full cubic volume, and they are entirely covered up by very long and heavy garments. The folds of these are pressed and pleated on the very thin shapes and uniformly arranged on both sides of the figures in long concave curves, forming a kind of zigzag pattern at the border; the contours are very tense, with the elasticity of drawn bow-strings. When this type of draping is fully developed the drawn out, curving mantle-folds may suggest wings.

Temple Grottoes at Lung Men.—The same energetic style as in the best Yün Kang sculptures may also be observed in some of the statues in the famous temple grottoes at Lung Men in Honan which were begun shortly after the Northern Wei dynasty had transferred its capital to Loyang (494). During the last decade these caves have been so badly destroyed that hardly 10% of the original sculpture still remains; all the rest is either smashed or beheaded, some of the heads being replaced by clay substitutes of a very provincial type. The most beautiful and earliest sculptures at Lung Men are to be found in the so-called Lao Chun Tung cave which is decorated from ceiling to floor with a great number of niches of varying sizes in which Buddhas and Bodhisattvas are grouped, either alone or together with adoring bikshus or other attendants. The majority of these sculptures were executed in the 3rd or 4th decade of the 6th century, but only some of the minor reliefs remain still in a fair condition. Yet some characteristic positions may be observed, for instance the cross-ankled Bodhisattvas which represent Maitreya, the coming Buddha, while the Buddha Sakyamuni is seated with legs straight down. The stylization of the folds is carried out according to the same patterns as in the Yün Kang caves, but the stone is harder and the technique is superior to that of the earlier Yün Kang sculptures. Some of these Lung Men sculptures have certainly been among the finest works of their kind in China.

Another variation of the Northern Wei period style may be observed in the sculptures which decorate the temple caves at Shih Ku Ssu, near Kung Hsien in Honan. The work was here started about the same time as at Lung Men but the material is of a softer kind and the technique is not quite so fine. The large central Buddha at this place, which now stands up to its knees in mud, is a broad and block-like figure modelled in very large planes, with a remarkable cubistic tendency, which also may be observed in several minor heads from the same place, now dispersed in various European and American museums.

Buddhist Stelae.—Besides these cave sculptures of the Northern Wei period should be mentioned a large number of Buddhist stelae, i.e., slabs with figures in high relief, varying in size, some up to 12 ft. high, others quite small. Their decoration consists generally of a combination of niches with Buddhist figures and ornamental borders. On the back of these slabs are often found long rows of figures in flat relief representing the donors of the monuments. This form of stelae was probably developed from the earlier type of inscribed memorial stones, as used in China since the Han dynasty. It is worth noticing that we find at the top of the Buddhist stelae the same kind of winding and interlacing dragons as on the slabs which were raised at the tombs; their fierceness and energy of movement seem to reveal their derivation from the Sibero-Asiatic art, based on Scythian traditions which, indeed, had a great influence on the development of the ornamental style of this period.

Transition Period.—The stylistic ideals of the Northern Wei period retained their importance until the middle of the 6th century. About this time a new wave of artistic influence reached China from northern India. It may be quite clearly observed in some of the monuments which were executed during the Northern Ch'i and Northern Chou dynasties (550–581). The best cave sculptures from this time existed, at least a few years ago, at T'ien Lung Shan not far from Taiyuan-fu in Shansi. They were started in the Northern Ch'i period and continued, with some intermissions during the Sui and T'ang dynasties.

Sculptures at T'ien Lung Shan.—The earliest sculptures at T'ien Lung Shan are to be found in the caves no. 2, 3, 10 and

16, probably executed between 560 and 580. The system of decoration in the first two caves consists of three large groups, one on each wall representing a seated Buddha accompanied by two Bodhisattvas and, in some instances, also by adoring monks and donors, characterized with striking realism. The main figures are executed in very high relief, giving almost the impression of free-standing forms, yet there is a certain flatness about them, noticeable particularly in the Bodhisattvas which stand turned half-way towards the central Buddha and whose garments—arranged in pleated folds—spread out in wing-like fashion at the sides. They are not very far removed stylistically from corresponding figures on later Wei monuments, though their heads are less archaic both in shape and expression.

The maturest examples of this transition period—possibly executed as late as 580—are to be found in the 16th cave at T'ien Lung Shan, where all the three walls are decorated with large groups of Buddhas with Bodhisattvas and other attendants placed on raised platforms, the fronts of which were decorated with representations of dwarf musicians. The central Buddhas are lifted into commanding positions on high pedestals in the form of lotus-flowers or altars; their shapes are full and well rounded, their heads comparatively small for the strong bodies. They are all seated in the same cross-legged posture, with bare feet and hands in the *abhaya* and *vara mudra* (gestures signifying "without fear" and "charity"). Their mantles, which are made of a very thin material, are draped only over the left shoulder, leaving the right bare, and the folds have practically no relief. Buddhas clothed in this fashion are very rare in Chinese art; they may occasionally be found in later T'ang sculpture but at this early period they are certainly surprises.

Foreign Influence.—The most probable explanation of this apparent anachronism in the style of the Buddhas seems to be that they were made from foreign models or by foreign artists while the less important side figures were carved in accordance with the indigenous principles of style. The figures are altogether Indian in spirit and form. It is hard to believe that Chinese artists would have been able to reproduce Mathura models so faithfully as we find them here, and it may at least be claimed that they have never done it better, either before or after. Possibly some Indian artist, well acquainted with the Mathura school, worked for some time at T'ien Lung Shan.

The same general types and principles of style which characterize the sculpture at T'ien Lung Shan may also be found in some isolated statues coming from this or a similar centre of sculptural activity. The most characteristic feature of all these figures is the cylindrical shape indicated in the legs and arms, as well as in the shape of the whole body, which often stands like a column on the lotus pedestal. Nothing can be more unlike the comparatively flat and angular shapes of the Northern Wei figures, which even when they have a more developed plastic form are linear rather than rounded.

Sculptures from Chihli Province.—Another provincial variation of the transition style may be seen in the sculptures from Chihli, the present metropolitan province, and particularly from Ting Chou where the supply of a beautiful white marble was abundant. The artistic quality of these sculptures is however quite uneven; the best of them stand on the highest level of Buddhist art in China, while the poorest are hardly more than ordinary artisans' work. Several figures of this group might be quoted as proofs of what already has been said about the plastic formula during this transition period. Their shapes are more or less cylindrical, their heads mostly large and heavy. One may notice a general tendency to make the figures narrower towards the feet and to broaden them towards the shoulders. The thin garments fit tightly over the bodies and their softly curving folds are indicated in quite low relief or simply with incised lines. Good examples of such statues are in the Metropolitan Museum in New York. If we place such a figure beside some characteristic example of the Northern Wei art, we may observe two opposite tendencies of style. In the earlier works the mantle folds and the contours are stretched and bent outward at the feet, the shoulders are narrow, the heads small; the rhythm is rising. In

the later ones the rhythm is falling instead of rising, the tempo is slow, not without heaviness; there is no bending of the contours, they are falling almost straight down; the mantle hangs over the body and it is only towards the feet, where the circumference becomes smaller, that a certain acceleration of the tempo is noticeable.

The Sui Dynasty.—The sculptures of the Sui period (581-618) form, stylistically, a direct continuation of those of the transi-

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART
SCULPTURE OF THE TRANSITION PERIOD OF THE NORTHERN CH'I DYNASTY

tion period during the Northern Ch'i and Chow dynasties. Most of them are still examples of the transition style, but a few may well be classified among the most perfect works of religious statuary in China. Conditions were particularly favourable for the flourishing of religious art, and the formal development had not yet passed the point where it becomes an end in itself. Sui sculpture is, on the whole, quite restrained in its formal modes of expression and its interest in nature is slight, but it marks nevertheless a distinct progress in the representation of actual forms.

T'ien Lung Statues.—Some good examples of the particular style of this period are to be found in the 8th grotto at T'ien Lung Shan which is in part preserved, although the soft material has been worn by time and water and some of the statues have been smashed and decapitated. Coming to these statues from a study of the sculptures in cave 16 at the same place (mentioned above), the first thing that strikes one is that they are not at all Indian in their general appearance. The Buddhas are seated in the same postures as the earlier ones but vested in the Chinese fashion with an upper garment covering both shoulders and with a less hieratic bearing of the stiff bodies. The shoulders are not so broad, the waist less curving, the forms are quite undifferentiated, but the heads have increased in size and have a more human air. They are certainly more Chinese, though in a provincial sense, and they are executed by inferior artists with little feeling for rhythmic lines and decorative beauty.

Most interesting are the two pairs of Dvarapalas (guardians) outside this cave. One pair is placed at the sides of the entrance, the other at each side of a tablet near by which still contains traces of an inscription of the Sui dynasty (said to have been dated 584). The attitudes of these guardian figures are highly dramatic, not to say strained. The movement of the arms is jerky, the turning of the heads, which are looking over the shoulder, is violent. The impetuosity is, indeed, much greater in these figures than in the Dvarapala statues at the earlier caves, but whether they have gained in sculptural quality as much as in dramatic force is less certain.

Typical expressions of the plastic formula of the Sui period are also to be found among the sculptures from Chihli, easily recognizable by their material which is a micaceous white marble. Common to them all is the general shape which is no longer simply pillar-like or cylindrical, but ovoid. The contours are swelling out over the hips and elbows and gradually draw closer toward the feet and over the head. Thus a general formula is created, and it

CHINESE SCULPTURES OF THE SUI PERIOD

1. Seated Buddha accompanied by two Bodhisattvas and two monks, Cave 16 at T'ien Lung Shan; Sui period, end of 6th century
2. Colossal Buddha in a cave at T'o Shan, Shantung; end of 6th century
3. Seated Buddha accompanied by a Bodhisattva, In a niche at Yun Men Shan, Shantung
4. Upper part of a Bodhisattva, Yun Men Shan, Shantung

is often repeated on a smaller scale in the heads. The same rhythm is taken up by the folds which in some of the figures form a succession of curves over the front endowing them with a more complete harmony and repose than may be expressed by any other shape or formula known to us.

Shantung Sculptures.—The richest and most varied provincial group of sculptures from the Sui period is to be found in Shantung. The religious fervour and interest in establishing Buddhist temples and sanctuaries seem to have been particularly great in this part of the country and, to judge from the sculptures still preserved in several of these caves, there must have existed an important tradition of religious art which was now revived by various masters of no common ability. The earliest caves are at T'o Shan and Yü Han Shan; at the latter place many of the figures are dated in the 4th, 5th and 6th year of the K'ai Huang era (584-586), but unfortunately they are largely restored with plaster and crude colouring.

The great sculptures in the second and third cave at T'o Shan belong practically to the same stylistic group as those at Yü Han Shan. None of them bears a definite date, but, to judge from their style, they must have been executed about the same time as those mentioned above, *i.e.*, about the middle of the '80s. The typical Sui formula for single figures has been enlarged on an enormous scale, not without some loss of plastic beauty and intimacy. The great Buddhas which are seated in cross-legged position on a low pedestal impress us more as a kind of architectural monolith than as plastically conceived sculptures. It is only the folds of the hem, falling over the pedestal, that have a livelier rhythm; here one may observe the very characteristic meandering wave-line which returns in most sculptures of the Sui period, and some overlapping larger curves divided by the no less significant ear-like curves.

Passing from the cave sculptures at T'o Shan to those at Yün Men Shan, which is situated across the valley, means moving into a quite different artistic centre. There are only a few large statues at Yün Men Shan and some of these are in a deplorable state of preservation, but whatever remains here is of remarkably fine artistic quality. No doubt, these sculptures are a little later than those in the caves at T'o Shan, though hardly more than ten years; the dates that are found in some of the small niches at the side of the main figures range from 596 to 599. The figures are not placed in real caves but in flat niches, and may thus be seen to more advantage than most cave sculptures in their original position; the actual play of light and shade adds something to the plastic effect.

The Yün Men Shan Buddha.—The principal group consists of a seated Buddha accompanied by a standing Bodhisattva and another figure which may have been a Dvarapala (now practically destroyed). Close to this is another still flatter niche which never contained any central statue, only a large tablet, which is now removed, and on each side of it two monumental Bodhisattvas.

The great Buddha is seated on a dais in the traditional posture with the legs crossed in front, and entirely covered by the wide mantle. The bearing of the body is, however, quite different; instead of the old stiffness there is a certain ease in the posture, a repose without any strain. He seems to lean against the wall of the niche, moving the head slightly forward as if intent on looking at something in front. The upper garment which is fastened with a string knot on the left shoulder is draped in quite broad curves between the knees. The folds are not simply ornamental or expressive of a linear rhythm, but modelled with fine gradations of light and shade, sometimes even undercut. They have become means of primary importance for creating a sculptural effect. The head is treated in a new individual manner with broad effects of light and shade. The eyes are not closed or half closed, as in most of the earlier Buddhas, but wide open, and the eyelids are undercut, which adds greatly to the impression of life. The lips are also separated by a deep shadow, as if they were opening. The whole treatment is quite exceptional and bears witness to an impressionistic style; strictly speaking, it remains an isolated phenomenon in Chinese sculpture.

The T'ang Dynasty.—It would indeed be wrong to imagine

that there is an absolute break or a deep-rooted difference between the sculpture of the Sui and that of the T'ang period; quite the opposite. T'ang sculpture is stylistically an immediate successor to the art of the Sui period. When we, for convenience sake, use the dynastic names and dates also in the domain of art, it should be clearly understood that they do not signify here the same kind of opposites or renewals as in the political history of the country. Artistic evolution in China is a slow and gradual process, which only to a minor degree is conditioned by the political events.

It may also be recalled that the T'ang dynasty reigned during a longer time than most of the preceding dynasties (619-960), and the plastic arts remained by no means the same during this whole period. The production of sculpture was very intense during the first 100 years of the period, but became soon afterwards comparatively weak and insignificant. In speaking about T'ang sculpture we mean the art up to about 725, which may be considered the most mature and perfect kind of Buddhist sculpture in China. It reflects something of the same creative and expansive power that we may observe in other manifestations of T'ang culture. Its best products are characterized by a plenitude, not to say magnificence, that can hardly be found in the art of earlier epochs. The forms grow full and strong, the decoration becomes rich and exuberant, gradually approaching what we should call baroque.

An important element in this evolution was due to the growing inter-communication between China and the western Asiatic centres of artistic activity, particularly the Sassanian empire. Many new impulses were derived thence and grafted upon the old stock of Chinese art, modifying it more and more in the direction of Western ideals of style. Generally speaking, it may be said that the current that came from India was of the greatest importance for the Buddhist sculpture, while the influences from Persian art are most plainly discernible in the ornamentation of minor objects in bronze and silver.

In order to illustrate these two main currents, as well as other important elements of style in the plastic art of the T'ang period, it would be well to take into consideration other artistic products besides stone sculptures, such as objects in bronze, silver, clay and lacquer, which reflect the aesthetic ideals of the time, but this would carry us beyond the limits of this short study. Buddhist statues still form the most important province within the plastic arts of the T'ang period, though it should also be remembered that some large tomb sculptures were executed at this time, including magnificent representations of lions and horses at the tombs of the great emperors, T'ai Tsung (d. 649) and Kao Tsung (d. 683).

The Shensi Sculptures.—The early T'ang sculptures from Shensi, which then was the metropolitan province, are made in a very hard, grey limestone or in a dense yellowish marble. The fine quality of the material demands a highly developed technique in order to yield good plastic effects and ornamental details, and it may well be admitted that as far as workmanship goes many of these statues stand on the highest level of Chinese sculpture, but the artistic quality is often less remarkable. The earliest dated statue of this period known to us is of the year 639; it represents a Buddha seated in cross-legged position on a high, draped pedestal placed in front of a background slab which is bordered like a nimbus with flame ornaments. The figure is draped in a mantle which covers both shoulders, arms and feet, leaving only a small part of the chest bare. The folds are highly conventionalized in the form of thin, rounded creases and arranged in long curves over the body, the legs and the upper part of the pedestal. The decorative effect is altogether more powerful and concentrated than in earlier statues of a similar kind, and the execution is masterly. Although made in stone, the statue gives the impression of a work cast in bronze, an impression which is supported by the dark metallic hue of the hard stone.

Influence of Indian Art.—Some Bodhisattva statues, of which two may be seen in the University museum in Philadelphia, illustrate still better an increasing influence from Indian art not only by their costumes and decorative ornaments but also by their bearing and formal character. They stand no longer in stiff up-

right positions with the weight of the body evenly divided on both feet; the one leg is slightly curved and moved backward, the other serves as a support for the body which consequently is curving, a movement which is continued in the neck and in the more or less marked inclination of the head. The upper part of the body is bare, except for the jewelled necklaces and the narrow scarf draped over the shoulder; the chest is well developed and the waist rather narrow. The *dhōti*, which is tied with a sash round the hips, falls in a series of curving folds over each leg, and these are indicated in the same fashion as the folds of the Buddha mentioned above. It should also be noticed that these figures do not wear a crown or a diadem on their heads like the early Bodhisattvas, but a high head-dress made up of thick winding plaits, a feature which also adds to their feminine aspect.

A kind of masculine pendant to these Bodhisattvas may be found among the statues of *bikshus* or monks, executed either as individual *post mortem* portraits or as parts of altar groups (examples of such statues may be seen in the museums in Philadelphia and Boston). They are less conventionalized, less dependent on foreign models and made in closer adherence to actual life. Their heads are portrait-like, their mantles arranged in a more or less natural fashion, thus, in many instances, approaching the small clay statuettes made for the tombs during the T'ang period as well as in earlier times. Some of these portrait statues may indeed be placed on a level with the best Roman sculptures. They are character studies, not so far individualized as Renaissance portraits, but very striking types, observed in actual life. It is also worth noticing how much freer and more plastic the draping of the mantle becomes in these statues. A figure such as the headless monk in the Boston museum might have been made by a Roman artist.

Honan Sculptures.—When we pass from the metropolitan province of Shensi into the adjoining province of Honan we may at once observe that the general character of the sculptures becomes modified. The provincial schools and stylistic differentiations seem on the whole to have become more developed at this time than at earlier epochs; it is now easier to distinguish the provincial currents.

The statues made in Honan, and particularly at the great artistic centre of Lung Men, where the decoration of the caves was continued during the 7th century, are generally more elegant than those originating from Shensi, though not always executed in such perfect technique. Unfortunately, the great majority of the early T'ang sculptures at Lung Men are partly or wholly destroyed—the heads being dispersed all over the world—so that it is now next to impossible to find there complete and good specimens of moderate size; we find them more easily in museums and private collections.

One of the finest examples is a large Bodhisattva statue, originally at Lung Men, but now in private hands in Peking. It may be taken as a representative of a large group of standing Bodhisattvas which all show the Indian influence grafted in Chinese types and shapes, a combination which in this particular instance has led to a perfectly harmonious result. The whole figure from the head-dress down to the feet is dominated by the softly gliding movement of the double S-curve (as in some Gothic madonnas) which would appear almost too accentuated, if it were not so perfectly balanced by the position of the arms. The contemporary Bodhisattvas from Shensi, represented in a similar position, appear quite stiff and hard beside this elegant and yet so dignified figure.

The Vairochana Buddha.—The colossal statues on the open terrace, which rises above the river at Lung Men, reflect in the most monumental form the religious pathos of the fully developed T'ang art. This is true particularly of the central figure, the great Vairochana Buddha; the side figures, two Bodhisattvas and two *bikshus* are decidedly inferior. The hands are destroyed, the lower part of the figure has suffered a great deal, but I doubt whether it ever made a stronger impression than to-day when it rises, high and free in the open air over the many surrounding niches in which time and human defilers have played havoc with most of the minor figures. The upper part of this giant is well preserved and more dominating now than ever. Long ages have softened

the mantle folds and roughened the surface of the grey limestone which is cracking all over, but they have not spoiled the impression of the plastic form. It may still be felt under the thin garment: a very sensitively modelled form, not a dead mass, though unified in a monumental sense. According to the inscription on the plinth the statue was made about 672–675.

The great power which is here reflected in such a harmonious and well-balanced form finds further dramatic expression in the

PLANS OF THE PRINCIPAL CAVES AT YÜN KANG, LUNG MEN AND T'ien LUNG SHAN

Dvarapalas which stand at the entrance to the so-called "lion cave." The bestial heads of the figures are amazing and terrible, and even the naked form is by no means represented from a naturalistic point of view, but as a symbol of strength and vigilance. Other Dvarapalas of the same date are sometimes represented in livelier postures, bending sideways or lifting one hand to deal a killing blow to any approaching enemy. The plastic effect is decidedly of a baroque nature, a tendency which is characteristic of the mature T'ang art whenever it leaves the well-trodden path of the traditional religious imagery and ventures on more naturalistic and dramatic representations.

Later T'ien Lung Shan Sculptures.—Another fairly homogeneous local group of T'ang sculpture may be observed in some of the later caves at T'ien Lung Shan where the artistic activity must have been kept up ever since the middle of the 6th century. During all these generations T'ien Lung Shan seems to have remained a special centre of Indian influence. Unfortunately, none of these sculptures is dated, and in some respects they fall outside

the general stylistic current of T'ang art. Some of them show plastic motives which really did not come into vogue until some time after 700, but this may be due to the fact that they were made under foreign influence. The earliest among these sculptures are remarkably fresh and subtle while the later ones are comparatively heavy and commonplace works. The best specimens of the earlier types are to be seen in caves 6 and 14, while the later ones are found in caves 17, 19, 20 and 21.

The main group on the back wall of cave 6 consists of a Buddha seated cross-legged on a high pedestal accompanied by two side figures, which, however, are almost eaten away by time and running water, but there is a Bodhisattva on the side wall which can still be enjoyed. The figure is seated on a round lotus pedestal with the legs folded but not crossed. He leans toward the right side and turns slightly in the waist, a movement which is accentuated by the turning of the head in the same direction. The left hand is placed on the leg in front as if to give added support to the body and make the free attitude still more restful. The body is entirely bare, except for a jewelled necklace and the narrow scarf which is draped in a diagonal curve from the right shoulder. The ease of the posture in conjunction with the sensitive modelling of the youthful body endow this figure with a sensual charm which is very seldom found in Chinese statues. It would hold its place beside the most exquisite French sculptures of the 18th century and yet it impresses us just as much by its dignity and composure.

A similar artistic conception is expressed in a still ampler form in a Bodhisattva statue in cave 16. The posture of the figure is a kind of *lalitasana* (position of ease). It is seated with the one leg pendant, the other bent crosswise over the seat, but the foot is not placed on the opposite leg. The left elbow is practically touching the knee, as if to support the body which leans over toward the side, turning at the same time slightly in the waist. The movement of the head follows in the opposite direction, producing thus a contraposto effect which, although not very pronounced, serves to bring out the beauty of the ripe body and the supple limbs. It may not have quite the charm of the one noticed above, but it shows an astonishingly free treatment of the mantle, the material being a kind of *draperie mouillée*.

None of the other caves at T'ien Lung Shan contains statues of a corresponding importance, although there are some which reveal the strong Indian influence both in their general shapes and in the treatment of their garments. The heads, which in late years have been knocked off and spread all over the Western world, are sometimes beautiful, though less expressive than the best heads from Lung Men or earlier centres of Buddhist sculpture in China.

Changes in Style.—Similar tendencies toward a freer plastic style may also be observed in contemporary sculptures from Shensi and Chihli. Among them may be seen beautiful Bodhisattvas which not only bend in the waist but also turn on the hips, making thus quite complicated movements, which tend to bring out the beauty and significance of their corporeal form. By these freer postures their likeness to ordinary human beings becomes more striking. They sometimes remind one of the complaint of the philosopher from the end of the T'ang period who said that the artists were losing their reverent attitude toward the religious motives and were representing the Bodhisattvas in the shape of court ladies.

The difference between the religious and the secular motives seems, as a matter of fact, to become less and less important, and one meets with quite realistic *genre* figures not only in clay but also executed on a large scale in stone, very much according to the same formula as the Bodhisattvas. As a good example of this class of work may be mentioned a statue of a young lady (in the Academy of Art in Tokyo) who sits on a bank with crossed legs playing a lute, while a dog and a cat are frolicking at her feet, a statue without any religious pretext, with the same amount of free and elegant realism as we know from the tomb statuettes in clay and from some T'ang paintings. Works of this kind indicate that the sculptors no longer remained satisfied with the purely religious inspiration but turned their attention towards nature and human life. If the evolution had continued along these lines,

the plastic arts in China might have become just as expressive and varied in their interpretations of purely artistic problems as Renaissance sculpture in Europe, but the creative power turned more and more from sculpture to painting.

Quite interesting as examples of the new tendencies of style are certain statues made at Ting Chou in Chihli, a centre of sculptural activity which, as we have seen, was important ever since the Northern Wei period. The best of these are surprisingly free and illustrate a new interest in movement and in the full development of the human figure. Among them may be mentioned a large statue of a headless Bodhisattva in the collection of Mrs. J. D. Rockefeller Jr. in New York, which is represented in a forward stride. The figure is composed in a similar way to some early Renaissance statues represented in a walking posture, e.g., St. John the Baptist—and shows the same shortcomings in the stiff limbs and the stilted rhythm, but also the same endeavour to treat the plastic form in the full round.

There are many other statues illustrating this tendency. The most original is perhaps a bare-headed monk who stands turned sideways with hands folded before the chest and head thrown back, looking almost straight upwards (in the collection of General Munthe, Peking). The movement expresses an intense religious devotion, not in the usual restrained and well-balanced form but with the flow of human feeling which leads our thoughts away from the Orient toward the most emotional religious art of Europe, such as we know it from the late Gothic and Baroque periods. The impressionistic treatment of the soft and heavy mantle points in the same direction.

The Post-T'ang Periods.—The production of religious sculpture decreases more and more towards the end of the T'ang period. Very few dated specimens are known from the 9th century, while those from the 8th are quite numerous. During the following periods of the Five Dynasties and the Northern Sung the creative energy of the nation, which in former times, particularly when religious devotion ran high, had been largely directed to the production of sculpture, turned to painting, which now definitely took the lead among the fine arts in China. The change in the relative importance of sculpture and painting is also illustrated by the fact that sculpture responded more and more to the influence of painting, an influence which became evident not only in the new impressionistic tendencies of style but also by the fact that other materials than stone and bronze came into vogue, particularly wood, clay, iron and lacquer-work, and these were usually treated with colour. Many of the new compositions introduced about this time were derived from contemporary paintings. It is true for instance of the very popular Kuanyin Bodhisattvas in the *maharajalila* (posture of royal ease) executed in stone, clay and wood, and it may also be observed in the combination of the figures with backgrounds treated like rocky landscapes or some kind of scenery with trees, buildings, animals and small human beings.

This more or less pictorial kind of sculpture spread all over northern China during the 12th and 13th centuries, when Buddhist art enjoyed a short period of refflorescence, and wooden sculpture particularly reached a high degree of perfection. A great number of wooden statues have in later years been brought from China to various Western collections, e.g., the museums in Philadelphia, Chicago and Toronto which alone contain more such statues than can be mentioned here. The majority of these represent either standing Bodhisattvas in long garments which often take on a fluttering movement toward the feet, or Kuanyins on rocky seats in the *maharajalila* posture. One of the standing figures in Toronto is said to have been dated by a tablet inserted in the figure in the year 1106, while one of the seated Kuanyins, lately belonging to the Ton Ying company in New York, carries an inscription with the date 1168. Similar ones are to be found in the British Museum, in the museums in Boston and Chicago, in the Musée Guimet and Collection Jean Sauphar in Paris, etc.

It is during this period that Kuanyin, the Bodhisattva of Mercy, definitely changes into a feminine being usually represented in a free and elegant form, whether she be seated on a rock by the water in the *maharajalila* posture, as in so many of

these wooden figures, or is standing, bending forward as if lending a listening ear to the invocations of her adorers. The womanly beauty is much more accentuated in these figures than any bodhisattvic qualities. The form has lost all its abstract serenity and become fluttering and emotional, but it is sometimes highly decorative in a new and more limited sense. Many of these figures seem to have been conceived not for a moral purpose, like the old Buddhas and Bodhisattvas, but simply to please the eye and the sentimental longings of the worshippers. Besides these wooden sculptures there are a good many made in stone, particularly series of Arhats, who are usually represented in series of 16 or 18, according to definite types and with more realistic than artistic expression. Interesting series of such Arhats executed in stone may be seen at the Yen Sha Tung and Ling Yen Ssu caves near Hangchow, as well as in the museum at Toronto. They are very uneven in quality and, on the whole, more interesting from an historical than from an artistic point of view.

Yuan Dynasty.—After the establishment of the Yüan dynasty (1280-1367) the position of the fine arts in China, including sculpture, changed considerably. The Mongols brought no new positive inspiration, on the contrary they destroyed more than they built up, except perhaps in the art of war. Art was useful to them only in so far as it could support and glorify the temporal power of the emperor and his generals. The religious attitude of the Yüan emperors was on the whole tolerant, but officialdom was then thoroughly Confucian and the Buddhists were pushed into the background. Taoism seems now to have held its place by the side of Buddhism. The cave sculptures at Hao Tien Kuan, south of T'aiyüan-fu in Shansi, executed at the end of the 13th century, are in this respect very interesting. Some of the compositions illustrating scenes from the life of the Taoist philosopher Pi Yün Ssu, besides a great number of other Immortals, reveal an evident interest in nature as, for instance, the old man on his deathbed; he is represented lying soundly asleep on the Chinese "kang" clad in a long garment. The most successful portions in these grottoes are, however, the purely decorative compositions, the low reliefs on the walls representing clouds and phoenixes, and the two guardians at the sides of one of the entrances whose fluttering draperies are arranged in ornamental curves. All these decorative designs are characterized by a buoyancy and a vigour which are hardly to be found in Chinese sculpture of the immediately preceding period. The motives are used for decoration rather than for the expression of purely plastic ideas. The pictorial tendency which characterizes the sculptures of the preceding period is still existent, although it has become coarser and of a more superficial kind. The same stylistic tendencies are also quite noticeable in a number of other sculptures of the same period, such as the four *Lokapalas* (guardians of the world) on the Chü Yung Kuan gate at Nank'ou, executed in 1345, and the Buddhist figures in a niche at Lung Tung Ssu near Tsinan-fu in Shantung, executed in 1318, not to speak of minor detached statues, dated at the beginning of the 14th century.

Ming Period.—When we enter into the Ming period (1368-1643) the dramatic power of expression seems to dry up more and more and the general artistic level is certainly not raised, although the production of Buddhist sculptures goes on with increasing abundance. Among the most popular and common creations of this time may be mentioned, for instance, series of Arhats in iron (good examples of such series are in the museums at Toronto and Gothenburg) which, however, seldom rise above the level of ordinary mass products made according to standard models. Similar motives are also treated in wood and lacquer, sometimes with good decorative effect, though with no more individual characterization. The sculpture of the Ming period is generally at its best when it takes up purely realistic motives instead of the traditional hieratic figures. It may thus become quite enjoyable in minor representations of mourners, musicians or similar *genre*-like motives, presented without any tendency to archaic restraint which otherwise is so apparent in the plastic arts of the Ming.

Summary.—Trying to sum up the general course of development of Chinese sculpture from the 10th to the 15th century in

a few words, we have to remember first the comparatively low level of religious sculpture towards the end of the Sung dynasty, particularly after the capital was moved from Kaifeng to Hangchow; secondly, the re-awakening of religious imagery in the northern provinces after the Tartar dynasties had got a firm hold on this part of the country (a flourishing sculptural activity, particularly in wood, developed there in the provinces of Chihli and Shansi); and thirdly, that with the Yüan dynasty a new foreign element appears which perhaps may be called Mongolian and which expresses itself on the one hand in a somewhat dry realism and on the other hand in a whirling linear ornamentation. The religious figures have still some life and expression of their own, though no real spirituality. This development was no longer continued during the Ming period. Whatever creative power may have been left did not turn towards the production of religious sculpture. It is true that a lot of statues, or rather statuettes, in bronze, wood, porcelain and ivory were produced but no great religious works, whether in stone or other materials. The Ming sculptors have given their best in the field of decorative art such as columns, balustrades, and other architectural details, but they created no new types of plastic works, whether religious or secular. They sought their inspiration much more in the imitation of earlier models than in any fresh efforts in the field of sculpture. CHINGFORD, an urban district of Essex, England, 12m. N.E. of London by the L.N.E.R. Pop. (1931) 22,051. It lies between the river Lea and the western outskirts of Epping Forest. The church of All Saints has Early English and Perpendicular remains. The half-timbered Queen Elizabeth's, or Fair Mead, hunting lodge is preserved under the Epping Forest Preservation Act. One of the finest oaks in the forest stands near it.

CHINGLEPUT, town and district, British India, in the Madras presidency. The town, situated 36 m. by rail from Madras, and a junction for a branch line to Arkonam, had a population in 1921 of 11,763. With Chandragiri in North Arcot, Chingleput was once the capital of the Vijayanagar kings, after their overthrow by the Mohammedans at Talikota in 1565. In 1639 a chief, subject to these kings, granted to the East India Company the land on which Fort St. George now stands. The fort built by the Vijayanagar kings in the 16th century, which was of strategic importance, was taken by the French in 1751, and retaken in 1752 by Clive, after which it proved invaluable to the British. It withstood Hyder Ali and afforded a refuge to the natives; and in 1780, after the defeat of Colonel W. Baillie, the army of Sir Hector Munro took refuge here. It is now partially ruined. The town is noted for its manufacture of pottery, and carries on a trade in rice. It is the centre of a Scotch Free Church mission, and has a reformatory school.

THE DISTRICT OF CHINGLEPUT surrounds the city of Madras, stretching along the coast for about 115 miles. The administrative headquarters are at Saidapet. Area 2,824 sq.m. Pop. (1921) 1,493,058. Salt is extensively manufactured along the coast, and fishing carried on. There are cotton and silk mills, tanneries, stone quarries and soapworks.

CHIN HILLS, a constituent hill-group of the mountain arc, stretching from the Arakan Yoma northwards to the Patkai hills, between Burma and India. This mountain arc, compressed at either end, has advanced farthest towards the west in the centre

CHINESE SCULPTURE: 7TH, 13TH, AND 14TH CENTURIES

1. Standing Bodhisattva, marble statue, end of T'ang period, now in a private collection in the United States
2. Kuanyin Bodhisattva, wooden statue, 13th century
3. Kuanyin Bodhisattva, wooden statue, 13th century
4. Virudhaka, one of the four Lokapālas (guardians of the universe), relief on the Chü Yung Kuan Gate, Nank'ou, Chih-li, dated 1345
5. Girl playing the lute, marble statue, end of T'ang period

where the long parallel folds are most numerous and the arc broadest. The Chin hills form the highest part of this central stretch. They consist simply of a succession of long narrow troughs and ridges, from 5,000 to 9,000 ft. high, with little flat land either in the valley bottoms or on the ridge tops. There is a marked climatic contrast between the humid tropical conditions of the deeply cut valleys and the cooler temperatures of the ridges. This contrast is reflected in the vegetation. Above 3,000 ft. the tropical forest gives way to oak and pine woods which in turn give way above 7,000 ft. to the rhododendron. A migratory form of agriculture, the *taungya* system, is practised in these hillside woods where the greater part of the population is centred. Clearings are made and the wood burnt for fertilizer. Such clearings are cultivated for two or three years and then abandoned. Bamboo, bracken and elephant grass then spring up with such vigour that natural re-afforestation is impossible. The main crop cultivated by this method is *jowar* millet contrasting with rice in the plains of Lower Burma. Some rice is, however, grown in the Chin hills on the lower slopes on terraces constructed with the help of felled timber.

The north-south trend lines of Indo-China as a whole have permitted the flooding of the region with "Mongoloid" peoples coming down from the north and have hindered east-west movement of both peoples and culture. The Arakan Yoma-Patkai mountain arc, of which the Chin hills form a part, exemplifies these features. It constitutes a frontier zone between Indian and Burmese cultures and its hill-tribes remained independent of British administration until the close of the 19th century. The Chin hills, lying on the Irrawaddy side of the watershed, were eventually occupied to prevent the raids by hill-folk on the plains of Burma. They are now administered primarily with the object of preserving the peace and of building up a sound government on the basis of the tribal system. The substitution of peaceful agriculture for raiding is producing changes in the distribution of population; the defensive hill-sites are being deserted and population is becoming concentrated on the more easily cultivable land. The whole of the southern part of the Arakan Yoma-Patkai mountain arc from the Chin hills southward into the Arakan Yoma is occupied by the Chin peoples who belong to the Southern Mongoloid race group and are linguistically a branch of the Tibeto-Burmans. The Chin hills proper are occupied by only the northern tribes of the Chin peoples. At the time of the 1921 Census the population of the Chin hills was 110,079. (P. M. R.)

CHINKIANG, a treaty port of China on the south bank of the Yangtze-kiang, 32° 11' N., 119° 24' E., 160 miles above Shanghai and 43 miles below Nanking. It lies where the north-south route of the Grand Canal from Hangchow to Peking crosses the east-west route of the Yangtze river. So long as the Grand Canal, linking the Yangtze Delta with the Imperial capital, remained an arterial line of communication, Chinkiang retained its significance. But traffic on the Grand Canal is now becoming increasingly local and its function as a north-south link is being usurped by the Tientsin-Pukow (Tsin-Pu) railway, which comes down to the Yangtze opposite Nanking, itself the terminus of a railway from Shanghai.

Chinkiang, although a station on the Shanghai-Nanking railway, has hence given place to Nanking in the command of the Yangtze crossing. Moreover the port of Chinkiang is experiencing local difficulties through silting. In consequence, while, since the first decade of the 20th century, the trade of neighbouring ports has continued to increase, that of Chinkiang has been arrested. In 1926, the total trade of the port was Hk. Tls. 29,200,583. The excess of imports over exports has continued to increase: in 1926 they were in the proportion of fifteen to one. The port is therefore functioning almost solely as a distributor of imported goods. The Chinese population is estimated at 150,000.

CHINO-JAPANESE WAR (1894-95). The causes of this conflict arose out of the immemorial rivalry of China and Japan for influence in Korea. In the 16th century a prolonged war in the peninsula had ended with the failure of Japan to make good her footing on the mainland—a failure brought about largely by lack of naval resources. In more modern times (1875, 1882, 1884)

Japan had repeatedly sent expeditions to Korea, and had fostered the growth of a progressive party in Seoul. The difficulties of 1884 were settled between China and Japan by the convention of Tientsin, wherein it was agreed that in the event of future intervention each should inform the other if it were decided to despatch troops to the peninsula. Nine years later the occasion arose. A serious rebellion induced the Korean Government to apply for military assistance from China. Early in June 1894 a small force of Chinese troops was sent to Asan, and Japan, duly informed of this action, replied by furnishing her minister at Seoul with an escort, rapidly following up this step by the despatch of about 5,000 troops under Maj.-Gen. Oshima. A complicated situation thus arose. Chinese troops were present in Korea by the request of the Government to put down rebellion. The Japanese controlled the capital, and declined to recognize Korea as a tributary of China. But they proposed that the two Powers should unite to suppress the disturbance and to inaugurate certain specified reforms. China considered that the measures of reform must be left to Korea herself. The reply was that Japan considered the Government of Korea "lacking in some of the elements which are essential to responsible independence." By the middle of July war had become inevitable unless the Peking Government were willing to abandon all claims over Korea, and as Chinese troops were already in the country by invitation, it was not to be expected that the shadowy suzerainty would be abandoned.

At Seoul the issue was forced by the Japanese minister, who delivered an ultimatum to the Korean Government on July 20. On the 23rd the palace was forcibly occupied. Meanwhile China had despatched about 8,000 troops to the Yalu river. The outbreak of war thus found the Japanese in possession of Seoul and ready to send large forces to Korea, while the Chinese occupied Asan (about 40m. south of the capital) and had a considerable body of troops in Manchuria in addition to those despatched to the Yalu river. To Japan the command of the sea was essential for the secure transport and supply of her troops. Without it the experience of the war of the 16th century would be repeated. China, too, could only utilize overland routes to Korea by submitting to the difficulties and delays entailed.

By the time war was finally declared (August 1), hostilities had already begun. On July 25 Oshima set out from Seoul to attack the Chinese at Asan. On the 29th he won a victory at Sŏnghwan, but the Chinese commander escaped with a considerable part of his forces by a détour to Ping-Yang (Phyŏng-Yang). Meanwhile a portion of the Japanese fleet had encountered some Chinese warships and transports off Phung-Tao, and scored an important success, sinking, amongst other vessels, the transport "Kowshing" (July 25). The loss of more than 1,000 Chinese soldiers in this vessel materially lightened Oshima's task. The intention of the Chinese to crush their enemies between their forces at Asan and Ping-Yang was completely frustrated, and the Japanese obtained control of all southern Korea.

Reinforcements from Japan were now pouring into Korea, and Gen. Nozu, the senior Japanese officer present, soon found himself in a position to move on Ping-Yang. Three columns converged upon the place on Sept. 15 and carried it after severe fighting.

Nearly all the troops on either side had been conveyed to the scene of war by sea, though the decisive contest for sea supremacy was still to be fought. The Chinese admiral Ting with the Northern squadron (which alone took part in the war) had hitherto remained inactive in Wei-hai-wei, and on the other side Vice-Admiral Ito's fleet had not directly interfered with the hostile transports which were reinforcing the troops on the Yalu. But two days after the battle of Ping-Yang, Ting, who had conveyed a large body of troops to the mouth of the Yalu, encountered the Japanese fleet on his return journey off Hai-Yang-Tao on Sept 17. The heavy battleships "Chên-Yuen" and "Ting-Yuen" constituted the strongest element of the Chinese squadron, for the Japanese, superior as they were in every other factor of success, had no vessels which could compare with these in the matter of protection. Ting advanced in a long irregular line abreast; the battleships in the centre, the lighter vessels on the wings. Ito's fast cruisers steamed in line ahead against the Chinese right wing;

crushing their weaker opponents with their fire. In the end the Chinese fleet was defeated and scattered, but the two heavy battleships drew off without serious injury. This battle of the Yalu gave Japan command of the sea, but Ito continued to act with great caution. The remnants of the vanquished fleet took refuge in Port Arthur, whence after repairs Ting proceeded to Wei-hai-wei.

The victory of Ping-Yang had cleared Korea of the Chinese troops, but on the lower Yalu—their own frontier—large forces threatened a second advance. Marshal Yamagata therefore took the offensive with his I. Army, and on Oct. 24 and 25, under great difficulties—though without serious opposition from the enemy—forced the passage of the river and occupied Chiu-lien-chêng. Part of the Chinese force retired to the north-east, part to Fêng-hwang-chêng and Hsiu-yuen. The Japanese I. Army advanced several columns towards the mountains of Manchuria to secure its conquests and prepare for a future advance. Gen. Tachimi's brigade, skirmishing with the enemy on the Moukden and Liao-Yang roads, found the Chinese in force. A simultaneous forward move by both sides led to the action of Tsao-ho-ku (Nov. 30), after which both sides withdrew—the Chinese to the line of the mountains covering Hai-chêng, Liao-Yang and Moukden, with the Tatar general Ikotenga's force 14,000 strong, on the Japanese right north-east of Fêng-hwang-chêng; and the Japanese to Chiu-lien-chêng, Takushan and Hsiu-yuen. The difficulties of supply in the hills were almost insurmountable, and no serious advance was intended by the Japanese until Jan. 1895, when it was to be made in co-operation with the II. Army. This army, under Marshal Oyama, had been formed in September and at first sent to Chemulpho as a support to the forces under Yamagata; but its chief task was the siege and capture of the Chinese fortress, dockyard and arsenal of Port Arthur.

The Liao-Tong peninsula was guarded by the walled city of Kin-chow and the forts of Ta-lien-wan (Dalny under the Russian régime, and Tairen under the Japanese) as well as the fortifications around Port Arthur itself. On Oct. 24 the disembarkation of the II. Army began near Pi-tse-wo, and the successive columns of the Japanese gradually moved towards Kin-chow, which was carried without difficulty. Even less resistance was offered by the modern forts of Ta-lien-wan. The Japanese now held a good harbour within a few miles of the main fortress. Here they landed siege artillery, and on Nov. 17 the advance was resumed. The attack was made on the 19th at dawn. Yamaji's division (Nogi's and Nishi's brigades), after a trying night march, assaulted and carried the western defences and moved upon the town. Hasegawa in the centre, as soon as Yamaji began to appear in rear of his opponents in the northern forts, pushed home his attack with equal success, and by 3 P.M. practically all resistance was at an end. The Japanese paid for this important success with but 423 casualties. Meanwhile the Chinese general Sung, who had marched from Hai-chêng to engage the II. Army, appeared before Kin-chow, where he received on the 22nd a severe repulse at the hands of the Japanese garrison. Soon after this overtures of peace were made by China; but her envoy, a foreigner unfurnished with credentials, was not received by the Tokyo Government.

The Japanese I. Army (now under Gen. Nozu) prepared, in spite of the season, to move across the mountains, and on Dec. 3 Gen. Katsura left Antung for Hai-chêng, which was safely occupied on Dec. 13. In the meantime Tachimi had moved northward from Fêng-hwang-chêng in order to distract the attention of the Chinese from Hai-chêng, and there were some small engagements between this force and that of Ikotenga, who ultimately retired beyond the mountains to Liao-Yang. Sung had already left Kai-ping to secure Hai-chêng when he heard of the fall of that place; his communications with Ikotenga being now severed, he swerved to the north-west and established a new base at Niu-chwang. Once on his new line Sung moved upon Hai-chêng. As it was essential that he should be prevented from joining forces with Ikotenga, Gen. Katsura marched out of Hai-chêng to fight him. At Kang-wang-tsai (Dec. 19) the Chinese displayed unusual steadiness, and it cost the Japanese some 343 casualties to dislodge the enemy. The victors returned to Hai-chêng exhausted with their efforts, but secure from attack for some time to come.

The advanced troops of the II. Army (Nogi's brigade) were now ready to advance, and only the Kai-ping garrison barred their junction with Katsura. At Kai-ping (Jan. 10) the resistance of the Chinese was almost as steady as at Kang-wang-tsai, and the Japanese lost 300 killed and wounded in their successful attack. In neither of these actions was the defeated force routed, nor did it retire very far. On Jan. 17 and again on the 22nd Ikotenga attacked Hai-chêng from the north, but was repulsed.

Meanwhile the II. Army, still under Oyama, had undertaken operations against Wei-hai-wei, the second great fortress and dockyard of northern China; and it was hoped that both armies would accomplish their present tasks in time to advance in the summer against Peking itself. On Jan. 18 a naval demonstration was made at Têng-chow-fu, 70m. west of Wei-hai-wei, and on the 19th the Japanese began their disembarkation at Yung-chêng Bay, about 12m. from Wei-hai-wei. The landing was scarcely opposed, and on the 26th the Japanese advance was begun. The south-eastern defences of Wei-hai-wei harbour were carried by the 6th Division, whilst the 2nd Division reached the inner waters of the bay, driving the Chinese before them. The fleet under Ito co-operated effectively. On the night of Feb. 4-5 the Chinese squadron in harbour was attacked by ten torpedo boats. Two boats were lost, but the armour-clad "Ting-Yuen" was sunk. On the following night a second attack was made, and three more vessels were sunk. On the 9th the "Chên-Yuen" was sunk by the guns in one of the captured forts. On the 12th Admiral Ting wrote to Admiral Ito offering to surrender, and then took poison, other officers following his example. Wei-hai-wei was then dismantled by the Japanese, and the II. Army concentrated at Port Arthur for the advance on Peking.

While this campaign was in progress the Chinese despatched a second peace mission, also with defective credentials. The Japanese declined to treat, and the mission returned to China. In February the Chinese made further unsuccessful attacks on Hai-chêng. Yamaji near Kai-ping fought a severe action on Feb. 21, 22 and 23, at Taping-shan against a part of Sung's army under Gen. Ma-yu-kun. This action was fought with 2ft. of snow on the ground, the thermometer registering zero F, and no less than 1,500 cases of frost-bite were reported. It was the intention of Gen. Nozu, after freeing the Hai-chêng garrison from Ikotenga, to seize Niu-chwang port. Two divisions converged on An-chan-chan, and the Chinese, threatened in front and flank, retired to Liao-Yang. The Japanese then moved on Niu-chwang, and Yamaji's 1st Division at Kai-ping joined in the advance. The column from An-shan-chan stormed Niu-chwang, which was obstinately defended, and cost the stormers nearly 400 men. All three divisions converged on Niu-chwang port (Ying-kow), and the final engagement took place at Tien-chwang-tai, which was captured on March 9. The Chinese forces in Manchuria being thoroughly broken and dispersed, there was nothing to prevent the Japanese from proceeding to the occupation of Peking, since they could, after the break-up of the ice, land and supply large forces at Shan-hai-kwan, within 170m. of the capital. Seven divisions were at Port Arthur ready to embark when negotiations were reopened. Li Hung-Chang proceeded to Shimonoseki, where the treaty was signed on April 17, 1895. An expedition was sent towards the end of March to the Pescadores, and later the Imperial Guard Division was sent to Formosa.

It is impossible to estimate the Chinese losses in the war. The Japanese lost 4,177 men by death in action or by sickness, and 56,862 were wounded or disabled by sickness, exclusive of the losses in the Formosa and Pescadores expeditions. Nearly two-thirds of these losses were incurred by the I. Army in the trying winter campaign in Manchuria.

La Guerre sino-japonaise* (Paris and Limoges).

CHINON, a town of western France, capital of an arrondissement in the department of Indre-et-Loire, on the bank of the Vienne, 32 m. S.W. of Tours. Pop. (1926) 4,169. It lies under a rocky height crowned by ruins of the famous castle, its narrow, winding streets containing many turreted houses of the 15th and 16th centuries. Chinon (Caño) existed before the Roman occupation of Gaul, and was from early times an important fortress. It was occupied by the Visigoths, and subsequently, after forming part of the royal domain, came to the counts of Touraine and from them to the counts of Anjou, in 1044. In the next century it passed to Henry II. of England, who died there, but it was won back to France by Philip Augustus in 1204, after a year's siege. Of its oldest church, the Romanesque St. Mexme, only the façade and nave are left. The church of St. Etienne dates from the 15th century, that of St. Maurice from the 12th, 15th and 16th centuries. The castle, which has undergone considerable modern restoration, consists of three separate strongholds. That to the east, the Château de St. Georges, built by Henry II. of England, has almost vanished, only the foundation of the outer wall remaining. The Château du Milieu (11th to 15th centuries) comprises the keep, the Pavillon de l'Horloge and the Grand Logis, where the first meeting between Joan of Arc and Charles VII. took place. Of the Château du Coudray, which is separated by a moat from the Château du Milieu, the chief remains are the Tour du Moulin (10th century) and two later towers. A statue of Rabelais, who was born in the vicinity of the town, stands on the river-quay. Basket and rope manufacture, tanning and cooperage are among the industries.

CHINOOK. This important American Indian people held Columbia river from the mouth to the Dalles, and adjacent territory. Their culture was a localized form of the North Pacific Coast type (*q.v.*), with plank houses, good canoes, trade, slavery, potlatch distributions of property, but without secret societies or totemic art. The language is distinctive, and a selection of words from it, much simplified phonetically and the grammar wholly done away with, forms the basis of the Chinook jargon. This trade language contains also French, English, Nutka and other Indian ingredients, and prevails from Oregon to Alaska. The Chinook were organized by settlements rather than tribes; some of their divisions are known as Clatsop, Wasco and Wishram. Estimated at 16,000 in 1805, they decreased (from disease) to a twentieth in the next 50 years, and now number perhaps 200-300, known under different names on several reservations containing ethnic mixtures.

See Lewis and Clark, *Original Journals* (1904); F. Boas, *Bur. Am. Ethn. Bull.* 20 (1895); E. Sapir, *Publ. Am. Ethn. Soc.*, vol. ii. (1909). (A. L. K.)

CHINOOK, the name given to a wind which blows from west or north over the Rocky Mountains, where it descends as a dry wind, warm in winter and cool in summer. It is due to a cyclone passing northward, and continues for a few hours to several days. It moderates the climate of the eastern Rockies, the snow melting quickly on account of its warmth and vanishing on account of its dryness, so that it is said to "lick up" the snow from the slopes.

CHINQUAPIN (*Castanea pumila*). A North American shrub or small tree of the beech family (Fagaceae), found chiefly in dry soils from New Jersey to Missouri and southward to Missouri and Texas. While usually shrubby eastward, it sometimes attains in Arkansas and Texas a height of 45 ft. and a trunk diameter of 3 feet. It is closely related to the chestnut (*q.v.*) from which it differs in its much smaller leaves, which are white-wooly beneath, and in its usually solitary nut, which, like that of the chestnut, is very sweet and edible. On the Pacific coast the name chinquapin is given to two species of *Castanopsis*, a genus very closely allied to the chestnut. The giant chinquapin or golden-leaved chestnut (*C. chrysophylla*), found from northern Oregon to southern California, is a magnificent tree which sometimes reaches a height of 150 ft. and a trunk diameter of 10 feet. The narrow, taper-pointed, evergreen leaves, 3 in. to 5 in. long, are closely clothed below, when young, with a fine golden wool. The fruit is chestnut-like, containing 1 or 2 nuts with a hard shell and a sweet kernel.

The bush chinquapin (*C. sempervirens*), of dry mountain slopes in California, is a spreading shrub, 1 ft. to 8 ft. high, with leaves 1½ to 3 in. long, usually not pointed at the apex. The wood of the giant chinquapin, which is reddish-brown, close- and straight-grained, takes a fine polish, but is not extensively utilized. The

CHINQUAPIN. BRANCH (LEFT) SHOWING SPINY BURR AND SOLITARY NUT; BRANCH (RIGHT) WITH MALE FLOWERS

bark, although devoid of tanning value, readily separates itself from the wood and is used to adulterate that of the tan bark oak.

CHINSURA, a town of British India, on the Hooghly river, 24m. above Calcutta, formerly the principal Dutch settlement in Bengal. The Dutch erected a fortified factory here in 1656. In 1759 a British force under Col. Forde was attacked by the garrison of Chinsura on its march to Chandernagore, but in less than half an hour the Dutch were entirely routed. Chinsura was taken by the British in 1781 on the outbreak of war with Holland and restored to the Dutch in 1783. Again, in 1795, during the Napoleonic wars, the settlement was occupied by a British garrison. At the peace of 1814 it was a second time restored to the Dutch. It was among the cessions in India made by the king of the Netherlands in 1825 in exchange for the British possessions in Sumatra. The Dutch church, commissioner's house, and cemetery (extended since 1825) are memorials of Dutch rule. Chinsura is included in the Hooghly-Chinsura municipality (pop. 29,958), and contains the Hooghly college.

CHINTZ, a word derived from the Hindu *chint*, spotted or variegated. This name was given to a kind of stained or painted calico produced in India. It is now applied to a highly glazed printed calico, commonly made in several colours on a light ground and used for bed hangings, covering furniture, etc.

CHINWANGTAO, 39° 56' N. 119° 38' E., a treaty port on the shores of the Gulf of Pechihli in north-east China; the port was created by, and the harbour is the property of, the Kailan Mining Administration, which works the Kaiping coalfield some 100 miles away. Export trade originates almost entirely from the coalfield and comprises not only coal but also coke, firebricks and cement manufactured at Tangshan, the new industrial town on the coalfield. Chinwangtao derives further significance from its character as the only ice-free port on the flat western shores of the shallow Gulf of Pechihli. It has therefore developed as a winter out-port to Tientsin, and to a lesser extent to Newchwang as well. This out-port function is not now quite as important as at the beginning of the present century. The navigation of the Hai-ho can now be kept open whenever the winds are off-shore and much of the trade that formerly went through Newchwang has since the advent of the Japanese been diverted through the ice-free Dairen. The port was first opened to foreign trade in 1901. The total trade in 1926 amounted to Hk. Tls. 15,465,421, of which about 60% was exports (the proportion of exports would be much greater if figures of weight instead of values were given) and of which foreign imports constituted only Hk. Tls. 1,925,060. The activities of the port are therefore connected with the coasting trade within the Far East

rather than with the international trade between the Far East and the rest of the world.

CHIOGGIA, a town and episcopal see of Venetia, Italy, in the province of Venice, from which it is 18½ m. S. by sea. Pop. (1921), 22,225 (town); 36,104 (commune). Chioggia is inhabited mostly by fishermen, and is situated upon an island at the south end of the lagoons. It is traversed by one main canal, La Vena, and has some picturesque and interesting mediaeval buildings. The peculiar dialect and customs of the inhabitants still survive to some extent. It is probably the Roman Portus Aedro, though its name is derived from the Roman Fossa Claudia, a canalized estuary which with the two mouths of the Meduacus (Brenta) went to form the harbour. In A.D. 672 it entered the league of the cities of the lagoons, and recognized the authority of the doge. In 809 it was almost destroyed by Pippin, but in 1110 was made a city, remaining subject to Venice. Chioggia is connected by rail with Rovigo, 35 m. to the south-west. (X.)

The Naval War of Chioggia (1378–1380).—The naval war of 1378–80, carried on by the Genoese and their allies against Venice, is of exceptional interest as one in which a superior naval power, having suffered disaster in home waters, was yet able to win by holding out till its squadrons in distant seas could be recalled for its defence.

Venice was mainly concerned for the safety of her trading stations in the Levant and the Black sea. The more powerful of her two fleets was sent to the eastern Mediterranean under Carlo Zeno, and the smaller to operate against the Genoese in the western Mediterranean, under Vettor Pisani. The possessions of Venice on the mainland were assailed by the lord of Carrara and the Hungarians, but this danger seemed trifling so long as Venice could keep the sea open to her trade.

At first she was entirely successful. While Carlo Zeno harassed the Genoese stations in the Levant, Pisani brought one of their squadrons to action in May, 1378, to the south of the Tiber, and defeated it. If Pisani had sailed direct to Genoa itself, which was thrown into a panic, he might have dictated peace, but he thought his squadron too weak, and followed the Genoese galleys which had fled to Famagusta in Cyprus. During the summer of 1378 he was employed partly off Cyprus, but mainly in taking and capturing the Istrian and Dalmatian towns which supported the Hungarians. He was ordered to winter on the coast of Istria, where his crews suffered from exposure and disease. Genoa now decided to attack Venice at home while the best of her ships were absent with Carlo Zeno, and sent a strong fleet under Luciano Doria. Pisani had been reinforced early in the spring of 1379, but when he was sighted by the Genoese fleet off Pola on May 7, he was slightly out-numbered, and his crews were still weak. He would have preferred to avoid action and to threaten the Genoese fleet from his base on the Istrian coast, but he was forced into battle by the Senate, and was defeated with great loss. On the other hand Luciano Doria himself was killed, and the Genoese, who had suffered severely, did not at once follow up their success. On the arrival of Pietro Doria, with reinforcements, they appeared off the Lido, the outer barrier of the lagoon of Venice, and in July began combined operations against Chioggia, co-operating with the Carrarese and the Hungarians. The Venetians had closed the passages through the outer banks except at the southern end, at the island of Brondolo, and the town of Chioggia. The barrier here approaches close to the mainland, and the position facilitated the co-operation of the allies; but Chioggia is some distance from Venice, which could only be reached across the lagoon, where the Venetians had taken up the buoys and had a light squadron. The allies, after occupying the island of Brondolo, attacked, and took the town of Chioggia on Aug. 13.

There was nothing now to prevent them from advancing on Venice itself except the difficult navigation of the lagoon. The Senate applied for peace, but the Genoese offered impossible terms. Pisani, who had been imprisoned after the defeat at Pola, was released and named commander-in-chief. The heavy Genoese vessels were much hampered by the intricate passages through the lagoon, and by using his own local knowledge, Pisani completely turned the tables on the invaders by a succession of night

attacks, during which he sank vessels in the canals leading through the lagoon to Venice, and in the fairways leading from Chioggia to the open sea. The Genoese were thus blockaded, Pisani having stationed his galleys in the open sea outside Brondolo. The Venetians themselves were in great distress; Carlo Zeno had long since been ordered home, but he was delayed by the difficulty of communication under 14th century conditions, and the besiegers of Chioggia were at the end of their strength when his fleet reached Brondolo on Jan. 1, 1380. The Genoese held out in the hope of relief from home, but it was not until May, 1380, that Matteo Maruffo arrived with reinforcements. By this time the Venetians had recovered the island, and their fleet occupied a fortified anchorage so that Maruffo could do nothing, and on June 24, 1380, the Genoese defenders of Chioggia surrendered. Venice, being now safe at home, recovered the command of the sea, and before the close of the year was able to make peace as a conqueror.

BIBLIOGRAPHY.—Horatio F. Brown, *Venice* (1839); S. Romanin, *Storia documentata di Venezia* (1855); W. C. Hazlitt, *History of the Venetian Republic* (1860). (G. A. R. C.; W. C. B. T.)

CHIOS, an island on the west coast of Asia Minor (ancient Greek *Xios*) about 30 m. long from north to south, and from 8 to 15 m. broad. The north end is mountainous with steep coasts; southwards there is open country, and great fertility. The capital, Castro, on the east coast, has a small safe harbour, and mediaeval fortifications. The climate is healthy; oranges, olives and even palms grow freely; the figs were famous in antiquity, but wine and gum mastic have always been the principal products. The latter, collected from a wild shrub, gives flavour and name to a popular Greek liqueur (*masticha*). Antimony, calamine and marble are worked; there is a tanning industry, and considerable coasting trade.

There are few remains of ancient Chios (on the same site as the modern); traces of a theatre and a temple of Athena Polichus; and about 6 m. N. of the city the curious "School of Homer," a sanctuary of Cybele, with altar and figure of the goddess with two lions, in the native rock of a hill-top. On the west coast is a rich monastery with a church founded by Constantine IX. Monomachus (1042–54). In antiquity Chios was famous for its school of epic poets, the Homeridae, who claimed descent from Homer, and probably did much to popularize the *Iliad* and *Odyssey* in early Greece. To Glaucus of Chios was ascribed the invention of iron-welding, early in the seventh century B.C., and his masterpiece, the support of a large bowl, was shown at Delphi: for his place in ancient art and craftsmanship see J. G. Frazer *Pausanias*: note on x. 16. 1. (vol. v. pp. 313–4). For the long sequence of Chian sculptors in marble see GREEK ART; and for the beautiful and instructive coinage, P. Gardner, *History of Greek Coinage* (index) and the *British Museum Catalogue* (s.v.).

The early history of Chios is obscure. There were Greek legends of Leleges, Pelasgi from Thessaly, a Cretan foundation "in the days of Rhadamanthus" (13th century), and of eventual colonization by Ionians from Attica four generations later. Early kings and tyrants are little more than names, but the long friendship with Miletus is significant and determined the hostility of Chios to its neighbours, Phocaea, Erythrae and Samos. The Chian colony at Maroneia on the coast of Thrace reinforced the wine-trade of the mother city. Like Miletus, Chios in 546 submitted to Cyrus as eagerly as Phocaea resisted him. When Miletus revolted, 100 Chian ships joined in offering desperate opposition at Lade (494). Persian reprisals were severe, and temporarily successful, for Chian ships, under the tyrant Strattis, served in the Persian fleet at Salamis. But in 479 Chios joined the Delian League and long remained a firm ally of the Athenians, retaining political independence and a navy of its own. But in 413 the island revolted, and was not recaptured. After the Peloponnesian War it renewed the Athenian alliance, but in 357 again seceded. It was reputed one of the best-governed states in Greece, for although it was governed alternately by oligarchs and democrats neither party persecuted the other severely. Late in the 4th century, however, civil dissension left it a prey to Idrieus, the dynast of Caria (346), and to the Persian admiral Memnon (333). During the Hellenistic age Chios retained its independence, supported the

Romans in their Eastern wars, and was made a "free and allied state." Under Roman and Byzantine rule industry and commerce were undisturbed, its chief export at this time being the "Arvisian wine," of the north-west coast (*Ariusia*). After temporary occupations by the Seljuk Turks (1089-1092) and by the Venetians (1124-1125, 1172, 1204-1225), it was given in fief to the Genoese family of Zaccaria, and in 1346 passed definitely into the hands of a Genoese *maona*, or trading company, which was organized in 1362 under the name of "the Giustiniani," and alone exploited the mastic trade; but the Greeks were allowed to retain their rights of self-government and continued to exercise their industries. In 1415 the Genoese became a tributary to the Ottomans and, in spite of occasional secessions which brought severe punishment (1453, 1479), the rule of the Giustiniani was not abolished till 1566. But capture and reconquest from the Florentines (1595) and the Venetians (1694-1695), greatly reduced the number of the Latins and wrecked its prosperity. Worst of all were the massacres of 1822, which followed upon an attack by Greek insurgents against the will of the natives. Many survivors fled to Syra (*q.v.*) and founded its prosperous carrying trade. In 1881 a severe earthquake destroyed over 5,600 persons and more than half the villages. But the island's natural resources made its recovery sure, and its efficient and peaceable inhabitants passed quietly from Turkish to Greek rule during the Balkan War of 1912.

CHIPMUNK, the common name in North America for the ground squirrel (*q.v.*).

CHIPPENDALE, THOMAS (c. 1718-1779), the most famous of English cabinet-makers, was the son of John Chippendale, a joiner of Otley, Yorkshire. He was baptised at Otley on June 5, 1718. The materials for the biography of Chippendale are scanty, but it is known that he came to London when he was about 20, and at the end of 1749 established himself in Conduit court, Long Acre, whence in 1753 he removed to No. 60, St. Martin's lane, which with the addition of the adjoining three houses remained his factory for the rest of his life.

It has always been exceedingly difficult to distinguish the work executed in Chippendale's factory and under his own eye from that of the many copyists and adapters who throughout the second half of the 18th century plundered remorselessly. Apart from his published designs, many of which were probably never made up, we have to depend upon the very few instances in which his original accounts earmark work as unquestionably his. For Claydon house, in Buckinghamshire, he executed much decorative work, and the best judges are satisfied that the Chinese bedroom there was designed by him. At Harewood house, in Yorkshire, we are on firmer ground. The house was furnished between 1765 and 1771, and both Robert Adam and Chippendale were employed upon it. Indeed, there is unmistakable evidence to show that certain work, so closely characteristic of the Adams that it might have been assigned to them without hesitation, was actually produced by Chippendale, whose bills for this Adam work are still preserved. For Nostell Priory, Yorkshire he made a quantity of fine furniture in 1766, the bills for which are also in existence there. Stourhead, the famous house of the Hoares in Wiltshire, contains much undoubted Chippendale furniture, which may, however, be the work of his son Thomas Chippendale II.; at Rowton castle Shropshire, Chippendale's bills as well as his works still exist.

Our other main source of information is *The Gentleman and Cabinet Maker's Director*, which was published by Thomas Chippendale in 1754. This folio, the most important collection of furniture designs issued up to that time in England, contains 160 engraved plates, and the list of subscribers indicates that the author had acquired a large and distinguished body of customers. There was a second edition in 1759, and a third in 1762.

The *Director* contains examples of each of the manners which Chippendale practised. Occasionally we find in one piece of furniture a combination of the three styles which he most affected at different periods (Louis XV., Chinese and Gothic) and it cannot be said that the result is as incongruous as might have been expected. Some of his most elegant and attractive work is derived directly from the French.

The primary characteristic of his furniture is solidity, but it is a solidity which rarely becomes heaviness. Even in apparently slight work, such as the ribbon-backed chair, construction is always the first consideration. It is indeed in the chair that Chippendale is seen at his best and most characteristic. From his hand, or his pencil, we have a great variety of chairs, which, although differing extensively in detail, may be roughly arranged in three or four groups, which it would sometimes be rash to attempt to date. He introduced the cabriole leg, which, despite its antiquity, came immediately from Holland; the claw and ball foot of ancient Oriental use; the straight, square, uncompromising early Georgian leg; the carved latticework Chinese leg; the pseudo-Chinese leg; the fretwork leg, which was supposed to be in the best Gothic taste; the inelegant rococo leg with the curled or hoofed foot; and even occasionally the spade foot. His chair-backs were very various. His efforts in Gothic often took the form of the tracery of a church window, or even of an ovalled rose window. His Chinese backs were distinctly geometrical, and from them he would seem to have derived some of the inspiration for the frets of the glazed bookcases and cabinets which were among his most agreeable work. The most attractive feature of Chippendale's most artistic chairs (derived from Louis Quinze models) is the back, which, speaking generally, is the most elegant and pleasing thing that has ever been done in furniture. He took the old solid or slightly pierced back, and cut it up into a light openwork design exquisitely carved (for Chippendale was a carver before everything) in a vast variety of designs ranging from the elaborate and extremely elegant ribbon back, to a comparatively plain but highly effective splat. His armchairs, however, often had solid or stuffed backs. Next to his chairs, Chippendale was most successful with settees, which almost invariably took the shape of two or three conjoined chairs, the arms, backs and legs identical with those which he used for single seats. He was likewise a prolific designer and maker of bookcases, cabinets and escritoires with doors glazed with fretwork divisions, cases for long clocks, and a great number of tables, some of them with a remarkable degree of Gallic grace. He was especially successful in designing small tables with fretwork galleries for the display of china. His mirrors, which were often in the Chinese taste or extravagantly rococo, are remarkable and characteristic. Some of Chippendale's most graceful work was lavished upon the woodwork of the lighter, more refined and less monumental four-poster. His claims to distinction are summed up in the fact that his name has by general consent been attached to the most splendid period of English furniture.

Chippendale was buried on Nov. 13, 1779, at the church of St. Martin-in-the-Fields. Of his 11 children, THOMAS CHIPPENDALE II. succeeded to the business of his father and grandfather, and for some years the firm traded under the style of Chippendale and Haig. The factory remained in St. Martin's lane, but in 1814 an additional shop was opened at No. 57, Haymarket, whence it was in 1821 removed to 42, Jernyn street. Like his father, Thomas Chippendale II. was a member of the Society of Arts; and he is known to have exhibited five pictures at the Royal Academy between 1784 and 1801. He died at the end of 1822, or the beginning of 1823.

See Oliver Brickett *Thomas Chippendale, a Study of his Life, Work and Influence* (1924).

CHIPPENHAM, market town and municipal borough in the Chippenham parliamentary division of Wiltshire, England, 94m. W. of London by the G.W.R. on the south side of the Upper Avon. Pop. (1931) 8,493. St. Andrew's church, originally 12th century Norman, has been enlarged in different styles. Chippenham (*Chepeham*, *Chippesham*) was the site of a royal residence where, in 853, Aethelwulf celebrated the marriage of his daughter Aethelswitha with Burhred, king of Mercia. The town figured prominently in the Danish invasion of the 9th century, and in 933 was the meeting-place of the witan. In the Domesday survey Chippenham appears as a Crown manor. The town was governed by a bailiff in the reign of Edward I.; it was incorporated under charter from Mary in 1553. In 1684 this charter was surrendered to Charles II., and in 1685 a new charter was received from James II., which was shortly abandoned in favour of the original grant. The derivation of Chippenham from *cyppan*, to buy, implies that the town possessed a market in Saxon times. The neighbouring Cotswold hills preserve many relics of early man, and their grasslands produced the sheep which gave Chippenham its fame as a woollen centre from the 16th century.

After the decline of its woollen and silk trades Chippenham became celebrated for grain and cheese markets. There is also metal-working, stone-quarrying, gardening and bacon-curing.

CHIPPEWA. The Canadian branch of the Chippewa, one of the largest tribes north of Mexico, lives in the woodlands north and west of Lake Superior. Their culture was typical in many respects of the central Algonquians. Moose, deer, beaver and rabbits were snared or killed with arrows; wild-fowl were shot or clubbed, and fish were speared or taken with hook and line. Wild rice was collected as a staple food in the vicinity of Lake Superior; maple sugar was manufactured, and nuts, berries and edible roots are still gathered in large quantities. In their search for game the Chippewa travel long distances, by canoe in summer, or in winter on snow-shoes, dragging their goods on toboggans. These wanderings, however, usually lead back to semi-permanent settlements, where formerly bark houses were used in warm weather, and oval, rush-covered lodges in winter. In pre-Columbian days, utensils were almost entirely of wood or bark, basketry being weakly developed. Clothing was of skins, while bags, belts and garters were woven on heddle looms out of bark or wild hemp fibre. Expert artificers in wood, Chippewa stone work was limited to arrow points and a few tools, while native copper, mined near Lake Superior, was pounded into serviceable shapes.

Politically, there is no Chippewa "tribe," since the numerous sub-divisions have no single, central authority. Each inhabits a certain locality, and the members enter into definite relations with one another. There is an ill-defined kind of council, consisting of practically all the males of the community, which elects a chief, whose powers are even more shadowy than those of the body that selects him. Social divisions are more definite, since, in addition to the family, there are exogamic patrilineal clans of a totemic nature. Individual ownership of material objects prevails, but land was probably held, in former times, by groups of kindred.

The Chippewa have firm belief in a cosmic force animating all nature which frequently manifests itself in animals, mythical or real. Like their eastern kinsmen, the concept of a guardian spirit was important, and shamanism with conjuring flourished. Entry to the next world depended largely upon membership in the *Midewiwin*, "Great Medicine Society," a secret organization entered after elaborate initiation. Symbolic pictographs drawn upon bark were perhaps originally connected with this society. (See *Handbook of the American Indian*, 1906.)

CHIPPEWA FALLS, a city of north-western Wisconsin, U.S.A., on the Chippewa river, 100 m. E. of St. Paul, the county

seat of Chippewa county. It is on Federal highway 53, and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, and the Soo Line railways. The population in 1930 was 9,539. The city has machine-shops and flour-mills, and its manufactures include woollen goods, shoes, gloves, bags, trunks, sashes and doors, beet sugar and cement silos. The first settlement was made in 1837. The city was chartered in 1870.

CHIPPING CAMPDEN, market town, Gloucestershire, England, on the Oxford and Worcester G.W.R. line. Pop. (1921) 1,627. It is picturesquely situated towards the north of the Cotswold Hills. A ruined manor house of the 16th century and some almshouses complete, with the church, a picturesque group of buildings.

Apart from a mediaeval tradition that a conference of Saxon kings was held there, the earliest record of Campden (*Campedene*) is in Domesday, when Earl Hugh held it. The manor passed in 1173 to Hugh de Gondeville, and about 1204 to Ralph, earl of Chester. These lords granted charters which are known from a confirmation dated 1247. In 1605 Campedene was incorporated, but was never represented in parliament. Camden speaks of the town as a market famous for stockings, a relic of its mediaeval importance as a mart for wool which gave it the name of Chipping. Pop. of rural district (1931) 8,298.

CHIPPING NORTON, municipal borough, Oxfordshire, England, 16m. N.W. of Oxford by a branch of the G.W.R. Pop. (1931) 3,489. It lies on the steep flank of a hill, and consists mainly of one very wide street. Chipping Norton (*Chepyngnorton*) was of some importance in Saxon times. At the Domesday survey it was held by Ernulf de Hesding and assessed at 15 hides with three mills. It returned two members to parliament as a borough in 1302 and 1304-1305, but was not represented after this date. Fairs were granted in 1205 to William Fitz-Alan and in 1276 to Roger, earl of March. In the reign of Henry VI. the market was held on Wednesday, and a fair was held at the Translation of St. Thomas Becket. These continued to be held in the reign of James I., who annulled the former two fairs, and granted others. He also granted the first and only charter of incorporation. The church of St. Mary the Virgin on the lower slope is a fine building in the Decorated and Perpendicular styles. The trade is still mainly agricultural. The borough is in the Banbury division of Oxfordshire. Area, 2,456 acres.

CHIKUITAN, an independent linguistic stock of South American Indians, so called from the Chiquitos who are the best known of its tribes. The stock occupies a considerable area in eastern Bolivia, in the forested hilly country on the northern border of the Chaco. In recent times they have held the area between the headwaters of the Guapore on the north and the hills on the northern bank of the Otuquis river on the south, and between the San Miguel river in the west and the Paraguay in the east. It is probable that they formerly extended farther west to the foothills of the Andes and may have been forced eastward as a result of the displacements of peoples consequent on the invasion and settlement of the Chiriguanos in the early 16th century. The Chiquitos were a rather warlike and originally mainly nomadic hunting and fishing folk of simple culture. Their name, meaning "little ones" in Spanish, was given them on account of the very small doorways of their tiny thatched huts, through which one had to crawl on hands and knees. They seem to have had some palisaded strongholds and to have used poisoned arrows. Some of the tribes made good pottery and simple textiles. They had no canoes. Monogamy was the rule except for the chiefs, who were not hereditary but chosen for valour and ability. The youth before marriage lived apart in a special house. The shamans appear to have used snakes a good deal in connection with their religious ceremonies. The best known tribe of this stock to-day is the Lenguas (*q.v.*).

See J. P. Fernandez, *Relacion historial de las misiones de los Indios que llaman Chiquitos*, etc. (Madrid, 1726).

CHIRICAHUA NATIONAL MONUMENT, a tract of 4,480 ac. in the Coronado national forest in Arizona, U.S.A., set apart as a Government reservation in 1924 and remarkable for its

"pinnacle" formations. It is administered by the Department of Agriculture.

CHIROL, SIR VALENTINE (1852–1929), British journalist, was born on May 23, 1852, and educated in France and Germany. He graduated Bachelier-ès-lettres of the University of Paris. From 1872 to 1876 he was a clerk in the Foreign Office and afterwards travelled throughout the Near and Far East. He succeeded Sir Donald Mackenzie Wallace in 1899 as foreign editor of *The Times* for which he had acted as correspondent in Berlin since 1892. He retired from the service of *The Times* in 1912, and then became a member of the Royal Commission on Indian Public Services (1912–16). He wrote authoritative works on India, Egypt and the Far and Near East, and in 1927, he published a volume of reminiscences entitled *Fifty Years in a Changing World* to which a second volume, *With Pen and Brush in Eastern Lands*, was added in 1929. He was knighted in 1912 and died in London on Oct. 22, 1929.

CHIROMANCY, the art of telling character or fortune by studying the lines of the hands (see **PALMISTRY**).

CHIRON or **CHEIRON**, in Greek mythology, one of the Centaurs, the son of Cronus and Philyra, a sea nymph. He dwelt at the foot of Mount Pelion, and was famous for his wisdom and knowledge of the healing art. He offers a remarkable contrast to the other Centaurs in manners and character. Many of the most celebrated heroes of Greece were brought up and instructed by him (Apollodorus iii. 10. 13). Accidentally pierced by a poisoned arrow shot by Heracles, he renounced his immortality in favour of Prometheus, and was placed by Zeus among the stars as the constellation *Sagittarius*.

See articles in Pauly-Wissowa's *Realencyclopädie* (1897) and W. H. Roscher's *Lexikon der Mythologie*; W. Mannhardt, *Wald- und Feldkulte* (1904).

CHIROPODIST, properly one who treats the ailments of the hands and feet, or is consulted as to keeping them in good condition; the use of the word is now restricted, however, to the care of the toes, "manicurist" having been invented for the corresponding attentions to the fingers. The word was first introduced in 1785, by a "corn-cutter" in Davies street, London.

CHIROPRACTIC, a method of treatment employed in the United States based on the assumption that most disease results from displacement of the vertebrae and pressure upon the nerves as they emerge, whereby they are prevented from transmitting to the various bodily organs the mental impulse necessary for proper functioning. The chiropractor never resorts to drugs or surgery; he merely tries to relieve the impinged nerve and leaves the rest to nature. Little was done to work out a theory in detail until 1895, when B. J. Palmer began its formulation, resulting in

the development of a system of articular adjustment with the hands. He established the Palmer School of Chiropractic (Chiropractic Fountain Head) at Davenport, Ia., and later others were founded in different parts of the United States. In 1926 there were said to be about 25,000 chiropractors in some 40 of the United States, of whom 15,000 were practising. In several states they were still debarred from practice, but 37 states had laws which accorded a measure of recognition to chiropractors.

CHIROPTERA (Greek for "hand-wings"), an order of mammals containing the bats, all of which are unique in the class in possessing the power of true flight, and have their fore-limbs specially modified for this purpose.

The mammals comprising this order are at once distinguished by the possession of true wings; the thorax is remarkably capacious, and the ribs are flattened and close together. The shoulder-girdle is greatly developed in comparison with the weak pelvic region. The fore-arm (fig. 1) consists of a rudimentary ulna, a long curved radius, and a carpus of six bones supporting a thumb and four elongated fingers, between which and the sides of the body and the hinder extremities is spread a thin expansion of skin, the wing-membrane. An elongated cartilaginous process (the calcar), rarely rudimentary or absent, arising from the inner side of the ankle joint, is directed inwards and supports part of the posterior margin of the interfemoral membrane, extending from the tail or hinder part of the body to the hind limbs. The penis is pendent; the testes are abdominal or inguinal, the teats, usually two in number, thoracic; the uterus is simple or with more or less long cornua; the placenta discoidal and deciduate; and the smooth cerebral hemispheres do not extend backwards over the cerebellum. The teeth comprise incisors, canines, premolars and molars; and the dental formula never exceeds $I\frac{3}{3}$, $C\frac{1}{1}$, $P\frac{3}{3}$, $M\frac{3}{3}$; total 38. The general number of dorso-lumbar vertebrae is 17, whereof 12 are dorsal; the cervical vertebrae are broad, but short. Except in fruit-bats (*Pteropodidae*), the vertebrae, from the third cervical backwards, are devoid of spinous processes.

The milk-teeth differ from those of all other mammals in that they are unlike those of the permanent series. They are slender, with pointed recurved cusps, and are soon shed, but exist for a short time with the permanent teeth. The permanent teeth exhibit great variety; in all species they are provided with well-developed roots, and their crowns are acutely tuberculate, with more or less well-defined W-shaped cusps in the insectivorous species, or variously hollowed out, or longitudinally grooved in the frugivorous kinds.

The clavicle is long, strong and curved; and the scapula large, oval and triangular, with a long curved coracoid process. The humerus, though long, is scarcely two-thirds the length of the

radius; and the rudimentary ulna is welded with the radius. A sesamoid bone exists in the tendon of the triceps muscle. The upper row of the carpus consists of the united scaphoid, lunar and cuneiform bones. The "hand" has five digits, the first, fourth and fifth of which consist each of a metacarpal and two phalanges; but in the second and third the number of phalanges is different in certain families. The first digit terminates in a claw, most

Fig. 2.—Flying Fox or Fruit Bat, (*Pteropus personatus*). Fig. 3.—Papuan Tube-Nosed Bat, (*Nyctymene major*). Fig. 4.—Mitred Horse-shoe Bat, (*Rhinolophus mitratus*). Fig. 5.—Blainville's Vampire, (*Mormoops blainvillii*). Fig. 6.—Lesser Javelin Vampire, (*Phyllostomus elongatum*). Fig. 7.—Long-tongued Vampire, (*Choeronycteris mexicana*), showing brush tipped tongue. Fig. 8.—Tom-Bat, (*Taphozous longimanus*), showing relative development of throat sacs in the male and female

developed in the frugivorous species, in most of which the second digit is also clawed, although in other bats this and the remaining digits are unarmed. In the weak pelvis the ilia are long and narrow, while in most species the pubes of opposite sides are loosely united in front in males, and widely separated in females. The foot consists of a short tarsus, and slender, laterally compressed toes, with much-curved claws.

Although the brain is of a low type, probably no animals possess so delicate a sense of touch as bats. In ordinary bats tactile organs exist, not only in the bristles on the sides of the muzzle, but in the sensitive structures forming the wing-membrane and ears, while in many species leaf-like expansions surrounding the nasal aperture or extending backwards behind them are developed. These nose-leaves are made up partly of the extended and thickened skin of the nostrils and partly of the glandular eminences occupying the sides of the muzzle, in which the sensitive bristles are implanted in other bats. In no mammals are the ears so developed or so variable in form; in most insectivorous species they are longer than the head, while in the long-eared bat their length nearly equals that of head and body. The "earlet," or tragus, is large, in some cases extending nearly to the outer margin of the conch; its function appears to be to intensify the waves of sound. In the *Rhinolophidae*, the only family of insectivorous bats in which the tragus is absent, the auditory bullae reach their greatest size, and the nasal appendages their highest development. In the fruit-eating bats the ear is simple and shows but slight variation. The oesophagus is narrow, especially in blood-sucking vampires. The stomach presents two types of structure, corresponding respectively to the two divisions of the order, *Megachiroptera* and *Microchiroptera*; in the former the pyloric extremity is, with one exception, elongated and folded upon itself, in the latter simple; an exceptional type is met with in the blood-sucker, or vampires, where the cardiac extremity is elongated, forming a long appendage. The intestine is comparatively

short, varying from one and a half to four times the length of the head and body, it is longer in the fruit-eating bats, shorter in the insectivorous species. The liver is characterized by the great size of the left lateral lobe, which occasionally equals half that of the whole organ; the right and left lateral fissures are usually very deep; in *Megachiroptera* the spigelian lobe is, with one exception, ill-defined or absent, and the caudate is generally large; but in *Microchiroptera* the former lobe is large, while the caudate is small. The gall-bladder is generally well-developed.

The wings consist of an "antebrachial membrane," which extends from the point of the shoulder along the humerus and more or less of the fore-arm to the base of the thumb, the metacarpal bone of which is partially or wholly included in it; the "wing-membrane" spreading out between the elongated fingers, and extending along the side of the body to the posterior extremities, generally reaching to the feet; and the "interfemoral membrane," the most variable of all, which is supported between the extremity of the body, the legs and the calcar (fig. 1.). The antebrachial and wing membranes are most developed in species fitted only for aerial locomotion which hang with the body enveloped in the wings when at rest. In the *Molossidae*, which are the best fitted for terrestrial progression, the antebrachial membrane is quite small and is not developed along the fore-arm, leaving the thumb quite free, while the wing-membrane is narrow and folded in repose under the fore-arm. Scent-glands and pouches opening on the surface of the skin are developed in many species, but in most cases more so in males than females. As a rule bats produce only a single offspring at a birth, which for some time is carried about by the mother, clinging to the fur of her breast.

Bats are divisible into two suborders, *Megachiroptera* and *Microchiroptera*.

MEGACHIROPTERA

The first of these suborders of bats comprises the fruit-eating species, which are generally of large size, with the crowns of the

BY COURTESY OF (A) ANTHONY, "NATURAL HISTORY," (B, C) FROM MILLER, "THE FAMILIES AND GENERA OF BATS" (U.S. NATIONAL MUSEUM)

FIG. 9.—VAMPIRE BAT (*DESMODUS*), SHOWING SHARP TEETH SPECIALLY ADAPTED FOR PUNCTURING SKIN TO SUCK BLOOD; B. MAXILLARY TEETH (UPPER TOOTH ROW); C. MANDIBULAR TEETH (LOWER TOOTH ROW)

cheek-teeth smooth and marked with a longitudinal groove. The bony palate is continued behind the last molar, narrowing slowly backwards; there are three phalanges in the index finger, the third phalange being terminated generally by a claw; the sides of the ear form a ring at the base; the tail when present, is inferior to (not contained in) the interfemoral membrane; the pyloric extremity of the stomach is generally much elongated; and the spigelian lobe of the liver is ill-defined or absent, while the caudate is well-developed. This group is limited to the tropical and sub-tropical parts of the eastern hemisphere.

All the members of this suborder are included in the single family Pteropodidae—which is subdivided into two subfamilies, (1) the Pteropodinae containing a large number of genera and the typical members of the family; and (2) the MacroGLOSSINAE, containing seven genera. The subfamily Pteropodinae is further divided into three sections, (a) the rousettine section, containing the typical fruit bats of the genus *Pteropus*, (b) the epomophorine

(A) BY COURTESY OF MR. GOODWIN, AMERICAN MUSEUM OF NATURAL HISTORY, FROM (B) "ANIMALS LIVING IN GARDENS OF THE ZOOLOGICAL SOCIETY" PUBLISHED BY THE SOCIETY, LONDON; (C) "BRITISH MAMMALS" (LONGMANS GREEN & CO.)

section containing only African genera, and (c) the cynopterine containing 11 genera from Africa and Asia. The subfamily Pteropodinae is distinguished from the MacroGLOSSINAE by the incisors being normal and the tongue not highly extensile. Members of this group range over the tropical and subtropical parts of the Old World, extending as far east as the Carolines and Samoa, but not to New Zealand. Commencing with the rousettine section, the nine genera may be classified in three subsections, (a) the rousettine branch, containing three genera, *Rousettus*, *Eidolon* and *Boneia*, characterized by the presence of a tail, and usually by having the third metacarpal slightly longer than the fourth and fifth; (b) the pteropine branch, containing four genera, *Pteropus*, *Acerodon*, *Pteralopex*, *Styloctenium*, in which the tail is absent and the fifth metacarpal usually longer than the third and fourth; and (c) the Dobsonian branch containing two genera, *Dobsonia* and *Harpyionycteris*, in which the tail is present or absent, and the third metacarpal usually distinctly the longest. The rousettine branch or subsection (about 20 species) is found throughout the whole area inhabited by the Megachiroptera, except Polynesia. The Pteropine branch (over 100 species and subspecies) covers the same area, including Polynesia, and excluding Africa and the eastern Mediterranean countries. The Dobsonian branch (13 species) is found in Austro-Malaya.

Commencing with the rousettine branch or subsection, the bats of the genus *Eidolon* are found only in Africa, Madagascar and southern Arabia. The African species, *E. helvum*, is found over a large part of Africa, extending from the Sudan to Namaqualand; it is a highly coloured bat, the fur of the body being a mixture of straw yellow and brownish. The genus *Rousettus* is also found in Africa, but extends eastwards as far as the Solomon islands. The skull is much the same as that of *Eidolon* but there is no bony auditory meatus, and the premaxillae are joined together in front, not separate as in *Eidolon*. In addition to fruit, some of these bats eat many insects; so great is the damage done to fruit crops that special measures have to be taken to protect the fruit from bats. *Rousettus* is divided into three subgenera, the typical one containing eight or nine species, widely

distributed throughout the greater part of the distributional area of the genus; and *Stenonycteris* and *Lissonycteris* both confined to the Ethiopian region. The two latter contain but a single species each, *R. (S.) lanosus* from east central Africa, and *R. (L.) angolensis* from west and central Africa. The genus *Boneia* also contains only a single species, *B. bidens*, from north Celebes; it agrees with *Eidolon* in having the premaxillae separated in front, but in most other respects resembles *Rousettus*. The great majority of fruit-bats are included in the genus *Pteropus*, the first genus of the pteropine subsection of the rousettine section, containing about 90 species widely spread over the greater part of the eastern hemisphere; although extending as far west as Madagascar and the island of Pemba, no examples of this genus have ever been found in Africa. The bats of this group are all of large size, one species from Java measuring as much as 5 ft. across the extended wings; they are popularly known as "flying foxes" and usually have reddish brown bodies and black naked wings. These bats live in large communities and before they go to sleep in the trees, a scene of incessant and noisy wrangling is enacted among them during the early hours of the morning. A common Indian flying fox, *P. giganteus*, feeds on a variety of fruits, such as mowhooa berries, figs, plantains and rose-apples, and is very partial to the flower buds of the silk-cotton tree (*Eriodendron orientale*). The various species inhabit the Malagasy and Oriental region, Austro-Malaya, north and eastern Australia, western Polynesia, north-west to Bonin and Formosa, and south-east to the Fiji, Tonga and Samoan islands.

Acerodon is closely allied to *Pteropus*, differing in the possession of a well-defined, antero-internal tubercle in p^4 and m^1 ; the six species inhabit the Celebes and Timor island groups, Talaut islands and Philippines. The third genus of this subsection, *Pteralopex*, is confined to the Solomon islands and contains only two species, which resemble *Pteropus* in size, but have the premaxillae co-ossified in front, not just in simple contact. The last genus

FROM MILLER, "THE FAMILIES AND GENERA OF BATS" (SMITHSONIAN INSTITUTION)

FIG. 11.—MILK DENTITION: A. *CYNOPTERUS MINUTUS*; B. *EPTESICUS FUSCUS*; C. *PROMOPS FOSTERI*, CARVED INCISORS OF AN INSECTIVOROUS BAT; D, F. CROWN AND SIDE VIEWS OF MAXILLARY MOLAR; E. MANDIBULAR MOLAR.

of this branch is *Styloctenium*, in which the first lower incisor is missing and the cheek teeth are $\frac{5}{5}$, not $\frac{5}{4}$ as in the rest of the group. The single species, *S. wallacei*, occurs only in the Celebes. The genus *Dobsonia* contains 12 species distributed over the Austro-Malayan subregion (Celebes, Flores, Timor, the Moluccas, New Guinea, Solomon islands, but not extending to Australia). *Harpyionycteris*, which contains but a single species (known only from one specimen), hails from the Philippines.

The epomophorine section may be divided into three branches (1) the Epomops branch, with a long rostrum and broad palate,

containing three genera *Plerotes* (1 species), *Epomops* (3 species), and *Hipsignathus* (1 species); (2) *Nanonycterine* branch, with a short rostrum, containing three genera *Nanonycteris*, *Scotonycteris* and *Casinonycteris*, each with a single species; and (3) the *Epomophorus* branch, with a variable rostrum and modified palatoides, containing two genera *Epomophorus* (about 8 species) and *Micropteropus* (1 species). The best known member of this

FROM MILLER, "THE FAMILIES AND GENERA OF BATS" (SMITHSONIAN INSTITUTION)
FIG. 12.—RHINOPOMA MICROPHYLLON, A MOUSE-TAILED BAT OF EGYPT
A. sternum; B and C. views of skull; D. lateral view of pelvis; E. dorsal view of pelvis; F. ventral view of pelvis

section is the hammer-headed bat (*H. monstrosus*) peculiar for the enormous head and enlarged muzzle, especially of the males. These bats frequent mangroves and palms along the river banks and feed largely on bananas, mango plums and soursops. It is found principally in west Africa (Gambia, Nigeria and Cameroons) but spreads as far east as Monbuttu.

The cynopterine section, remarkable for the shortened rostrum, contains 11 genera, the largest and most commonly met with being the typical genus, with six species and several subspecies. The various forms of *Cynopterus* are distributed over the greater part of the Oriental region, extending from the Indian peninsula eastwards as far as Celebes, Lombok and Timor, and from Nepal southwards to Sumatra and Java. *Myonycteris*, with four species, may be regarded in some ways as intermediate between the rousetine and cynopterine section, the rostrum being short, but not so short as in *Cynopterus*; the members of this genus are all African. The other cynopterine genera are: *Ptenochirus*, *Megaerops*, *Dyacopterus*, *Balionycteris*, *Chironax*, *Thoopterus*, *Penthetor*, *Sphaerias* and *Nyctimene*, all excepting the last having but a single species each. *Nyctimene* contains about 12 species distributed over the Austro-Malayan subregion.

The second subfamily of fruit-bats, the Macroglossinae, are distinguished from the Pteropodinae by the greater specialization of the tongue and the tongue-papillae—an adaptation to a diet consisting partly of pollen. Two sections of Macroglossinae have been distinguished—the eonycterine section containing four genera (*Eonycteris*, *Megaloglossus*, *Macroglossus*, *Syconycteris*) and the notoapterine section containing three genera (*Melonycteris*, *Nesonycteris* and *Notopteris*). One genus, *Notopteris*, is remarkable for the length of its tail, being the only living fruit-bat in which the tail has remained long.

MICROCHIROPTERA

The second and larger suborder, the Microchiroptera, includes all the insectivorous species, most of which are of relatively small size. Their teeth are usually of insectivorous type, the crowns being surmounted by sharp cusps. The ear-margin does not form a complete ring as in the fruit-bats, and the angular

process of the mandible is well-developed. The index finger never terminates in a claw, and the trochiter and trochin are large. As the suborder contains upwards of 600 different forms it will only be possible to give an outline of the various families, with special mention of some of the more important types.

The various genera may be grouped together into 16 families:—

(1) Family Rhinopomidae. Represented by a single genus *Rhinopoma*, distributed across Egypt to southern Asia as far as Burma and Sumatra. In this family the postorbital processes are absent and the second finger has two phalanges. These bats are characterised by a broad muzzle, with a rudimentary nose-leaf and excessively long tail, which gives these bats their popular name of mouse-tailed bats.

(2) Family Emballonuridae. Divided into two subfamilies Emballonurinae and Diclidurinae, the various forms are distributed over the tropical portions of both hemispheres, and are unknown in Australia and New Zealand. In this family postorbital processes are present and the second finger is without phalanges. The distinctive feature of these bats is the free tail-tip, which pierces the interfemoral membrane to appear on its upper surface.

In the *Emballonurinae* the postorbital processes are slender and the clavicle not expanded, whereas in the *Diclidurinae* the postorbital processes are broad and the clavicles markedly expanded. The typical group contains a number of genera, the best known of which are *Emballonura* and *Taphozous*. There are several forms of *Emballonura* (I_2^2 , C_1^1 , P_2^2 , M_3^3), one inhabiting Madagascar, the remainder spreading through the Malay peninsula and Sumatra eastwards to Samoa. The members of this genus are all small species and usually dark brown in colour. A closely allied genus, *Coleura*, comes from eastern Africa and the Seychelle islands; *C. afra*, the African species, is larger than *Emballonura*, pale brown in colour, and differs in having only a single incisor in each side of the upper jaw. The bats of the genus

FROM H. ALLEN, "ON THE GLOSSOPHAGINAE" BY COURTESY OF THE AMERICAN PHILOSOPHICAL SOCIETY

FIG. 13.—GLOSSOPHAGA SORICINA, COMMONEST OF GLOSSOPHAGINAE
A. head; B. skull vertex; C. skull profile; D. skull base; E. jaws seen from front; G. upper teeth; H. lower teeth from above; F. left lower molars

Taphozous are usually of considerable size, and have the frontal region of the skull concave; there are only two pairs of lower incisors, the dental formula being I_2^2 , C_1^1 , P_2^2 , M_3^3 . They are known as tomb-bats, and many of them have a glandular sac (fig. 8) between the angles of the lower jaw, more developed in males than in females. The Indian tomb-bat (*T. melanopogon*) is one of the best known of these bats; it is a fair sized species and drab brown in colour, with the pale hair-bases showing through. *T. longimanus*, from Tenasserim, is either bright orange-brown or dark drab-brown, and in *T. mauritanus*, from Africa, the

general colour is pale buff overlaid with a wavy pattern of silver and black. *Saccolaimus* is an allied genus occurring in Africa, Asia and Australia; *S. pelli*, from central Africa, is one of the largest of this group, the head and body measuring about 125 mm. in length. *S. affinis*, from the East Indies, has a brownish coat speckled with whitish, and the entire under parts are white, as are also the wing membranes. The Australian *S. flaviventris* is a very

A. head, showing the broad flat nose and almost naked ear; B. detailed view of ear; C. limbs, calcar and part of body; D. upper and lower jaws

handsome species, being velvety black above and pure white below. *Rhynchonycteris* and *Saccopteryx* are closely related to the typical genus, the former being small, greyish coloured bats, and the latter small, or medium sized, species, with two whitish stripes extending from the shoulders to the hind-quarters. These latter species are found only in tropical and subtropical America. *Cormura*, *Peropteryx*, *Peronymus*, *Centronycteris* and *Myropteryx* are other American genera belonging to this group.

The subfamily Diclidurinae is confined to tropical America and contains but a single genus, *Diclidurus*, with a dental formula of $I_3^1, C_1^1, P_2^2, M_3^3$; the three species are all white or whitish coloured bats.

(3) Family Noctilionidae. Probably allied to the Rhinopomidae and Emballonuridae as is indicated by the large trochin and small trochiter with its slight articulation with the scapula; teeth $I_3^1, C_1^1, P_2^2, M_3^3$. The family is confined to tropical America, north as far as southern Mexico and Cuba. Two genera may be distinguished, (a) *Noctilio*, characterized by its excessively long legs, large feet, strongly wrinkled lips, and long, pointed ears; (b) *Dirias*, resembling *Noctilio* but with shorter legs and feet. *N. leporinus* is brownish above with a white median stripe, extending from neck to tail, and the underneath parts are bright orange; measurements:—head and body 95 mm.; tail 24 mm.; hindfoot 27 mm. The members of the Noctilionidae are essentially fish-eating bats.

(4) Family Nycteridae. At one time the bats of this group were included in the Megadermidae (see below); they are recognizable by their long tails entirely enclosed in membrane and large ears with simple tragus, and deep frontal groove with leaf-like outgrowth. The single genus (*Nycteris*) is chiefly African, but is also represented in the Malay peninsula, Java, Timor, etc. The dental formula is $I_3^1, C_1^1, P_2^2, M_3^3$. *N. Luteola*, which is pale tobacco-brown above and white below, exhibits the following dimensions: head and body 60 mm.; tail 55 mm.; hindfoot 11 mm.; ear 32 mm.

(5) The family Megadermidae contains a large number of species, grouped in five genera, and includes some of the most bril-

liantly coloured members of the whole order. Closely allied to the preceding family, these bats are distinguished by their long, pointed nose-leaves, short tails, large ears with bifid tragi, and absence of upper incisors. They range over tropical Africa, southern Asia, the Philippines and Australia. Of the five genera two (*Megaderma* and *Lyroderma*) have the dental formula $I_2^0, C_1^1, P_2^2, M_3^3$; in the other three genera (*Macroderma*, *Lavia* and *Cardioderma*), there is only a single upper premolar on each side, the formula being $I_2^0, C_1^1, P_2^2, M_3^3$. *Megaderma spasma*, from India, has large, rounded ears, and is of a greenish soot-colour; the head and body measure 70–75 mm. *Macroderma* contains but a single species, *M. gigas*, from Australia; it is a very large bat with a body measurement of 125–130 mm., and ears about 50 mm. in length. *Megaderma* and *Lyroderma* are Asiatic, and *Lavia* and *Cardioderma* are African. *Lavia frons* from tropical Africa (the only known habitat of the genus) is about the same size as the typical *Megaderma* (head and body 75 mm., ears 42 mm.). The fur is bright greenish-grey in colour and the wings, in the living state, yellowish.

(6) Family Rhinolophidae. Toes (except hallux) with three phalanges each, premaxillae free from each other and from the maxillary bone; tragus absent. Dental formula $I_2^1, C_1^1, P_2^2, M_3^3$. This family which inhabits the tropical and temperate parts of the Old World, contains the single genus *Rhinolophus* (the well-known horse-shoe bats), the members of which are remarkable for their large and complicated nose-leaves and large ears. They vary considerably in size, in some species such as the lesser horse-shoe (*R. hipposideros*) the head and body measure only 50 mm. in length; in others, like the greater horse-shoe (*R. ferrum-equinum*) the head and body are from 65–75 mm.; in this latter species the fur is a pale grey snuff-brown in colour. In other species such as *R. rouxi* of India and *R. lobatus* of Africa, the colour of the fur is sometimes bright orange all over, sometimes dull greyish-brown. *R. perniger*, from Tenasserim, is one of the largest and richest coloured species; the general colour in this bat is deep sepia brown, and the nose-leaf and ears conspicuously large. More than 100 different forms of *Rhinolophus* are now recognized.

(7) Family Hipposideridae. Similar to the preceding but the toes with two phalanges each, the pelvic and pectoral girdles more highly modified, and the lumbar vertebrae tending to fuse together. Eight genera are recognised and range over a large area of the tropical parts of the Old World, extending northwards as far as the Himalayas and Morocco. The typical genus, *Hipposideros*, containing over 40 forms, presents the following dental formula: $I_2^1, C_1^1, P_2^2, M_3^3$. Some of these bats are of considerable size, the body measurement of *H. gigas* being as much as 125 mm.; while the ears attain a length of 35 mm.; others, like the common African species, *H. caffer*, are quite small (head and body 48 mm., tail 32 mm., ear 14 mm.). The former species is sometimes very brilliantly coloured, the fur of the body being a rich chestnut-orange tint, with a dark chestnut V-shaped marking on

FROM DOBSON, "MONOGRAPH OF THE ASIATIC CHIROPTERA"
FIG. 15.—SKULL OF MOUSE-TAILED BAT, (*RHINOPOMA MICROPHYLLUM*)

the hind-quarters; at other times the coat is greyish with a sooty-brown marking. *H. caffer* is also either orange-buff or sooty-brown in colour, and a species from central Africa, *H. cyclops*, presents a beautiful silvery-grey speckled effect. The genus is widely spread over the tropical parts of the Old World eastwards to Australia. A very beautifully coloured bat belonging to this family is *Ansellia tridens*, a small species which is sometimes brilliant chestnut red, above and below; it is found in north-eastern Africa (Sudan) and adjacent parts of Asia. *Anthops*, with a single species, *A. ornatus*, is a closely allied genus from the Solomon islands, distinguished by its short tail. The other genera of the family are *Coelops* (Bengal and Java), *Clootis* (East Africa), *Rhinyonycteris* (Australia) and *Triaenops* (Africa, Madagascar and Asia), which contain only a single or a few species each.

(8) Family Phyllostomidae. Bats of this group are characterized by the presence of three bony phalanges in the third finger, entire premaxillae, and well-developed molars. They are dis-

tributed over the warmer parts of America, northwards towards the southern United States and the Bahamas. The family has been subdivided into seven subfamilies, one of which, *Chilonycteridae*, is distinguished from the other six by the absence of a nose-leaf, and having the trochiter not articulating with the scapula. This subfamily contains three genera, *Chilonycteris*, *Pteronotus* and *Mormoops*, which include about 20 forms (dental formula $I_2^2, C_1^1, P_3^3, M_3^3$). The subfamily *Phyllostominae* contains about 14 genera of American leaf-nosed bats with normal teeth. Four of these genera, *Tonatia*, *Anthorina*, *Mimon* and *Chrotopterus*, have only one lower incisor on each side; the first of these genera has three lower premolars on each side, the others have only two. The remaining genera, including such well-known names as *Phyllostomus* and *Vampyrus*, have two lower incisors on each side. *Phyllostomus*, which is a fairly large genus containing a dozen forms, has the following dental formula: $I_2^2, C_1^1, P_3^3, M_3^3$. The species are all large and heavily built, the nose-leaf is well developed, and the ears small and separate. *P. hastatus*, a well-known species, measures 112 mm. from head to base of tail, the latter being 23 mm. in length, and the ear 30 mm. The colour of the hair is dark reddish brown or black. A smaller species *P. latifolium*, presents the following dimensions:—head and body 76 mm.; tail 12 mm.; ear 28 mm. *Chrotopterus*, which contains but a single species, *C. auritus*, hails from tropical America as far north as southern Mexico; this bat is a medium sized species (head and body 107 mm.) and sooty grey in colour. *Vampyrus*, also represented by a single species (*V. spectrum*), has the teeth arranged as follows:— $I_2^2, C_1^1, P_3^3, M_3^3$; this bat is large in size and reddish or dark brown in colour. It is not a blood-sucking bat, the name being due to mistaken identity. The remaining five subfamilies have abnormal molars with the cusps and commissures much reduced; *Glossophaginae* (about nine or ten genera) from the warmer parts of America, West Indies and Cuba; *Hemidermidae* (two genera of American and West Indian species); *Sturniridae*, containing the one species *Sturnira spectrum* from tropical America. The males of this bat have modified tufts of deep red hair in front of each shoulder; *Stenoderminae* (containing 19 or 20 genera) from America; these bats have highly abnormal teeth. One of the best known genera is *Artibeus*, characterized by the presence of white lines running from the nose to the ears above the eyes, and a white crescentic marking under each ear. These bats vary in size considerably, some species (*A. lituratus* etc.) measuring 105 mm. in length (head and body) while others do not exceed 50 mm. (*A. cinereus*). A closely allied genus, *Uroderma*, has similar head markings but, in addition, has a white stripe extending from the shoulders to the hind-quarters. In *Vampyrops* and *Vampyrodes* these markings are still more sharply defined. The last subfamily of this group is the *Phyllostominae*, containing three genera from the West Indies.

FROM DOBSON, "CATALOGUE OF THE CHIROPTERA," COURTESY OF THE BRITISH MUSEUM
FIG. 16.—HEAD OF CHILONATALUS MICROPUS

brae and the presence of a pedicellate sucking disc on the thumb and sole. The single genus (*Thyroptera*) is confined to tropical America.

(13) Family *Myzopodidae*. This family is based on a single species (*M. aurita*) from Madagascar.

(14) Family *Vespertilionidae*. The members of this almost universally distributed group are distinguished by their simple muzzles, well-developed tragi, long tails, and presence of only two bony phalanges in the third finger. The family is divided into six subfamilies, the best known of which is the *Vespertilioninae* containing over 30 genera; such well-known bats as the long-eared bats (*Plecotus*) and the pipistrelles (*Pipistrellus*) are included in this group, together with nearly 100 forms of *Myotis*. The other subfamilies are the *Murinae* (two Asiatic genera); *Kerivoulinae* (two genera, Africa, India, eastwards to New Guinea); *Nyctophilinae* (two genera, America, and Timor to the Fiji islands and Tasmania); and the *Tomopeatinae*, with one species only, *Tomopeas ravus*, from Peru. The genus *Kerivoula*, of the subfamily *Kerivoulinae*, contains some of the most handsomely coloured of all bats, *K. picta*, an Asiatic species, having a bright orange-buff body and orange-red wings with black markings. Other beautifully coloured species are found among the *Vespertilioninae*, such as *Myotis welwitschii* and *Glauconycteris papilio*. The former, which is a medium-sized bat (head and body 65 mm.; tail 55 mm.) has the hair on the body whitish, washed with bright brick-red, the interfemoral membrane and fingers red with black spots, and wing-membrane bluish-black veined with white. *Glauconycteris papilio*, an African species (head and body 62 mm.; tail 44 mm.) is pale yellowish above and pure white below, with interfemoral and wing-membranes whitish marked with dark veins. Another handsome bat belonging to this subfamily is *Chalinolobus gouldi* from Australia (head and body 65 mm., tail 45 mm.), which has the front part of its body velvety black shading into olive-brown behind. One of the largest bats in this group is *Scotophilus gigas*, from Africa, which measures 116 mm. in length (head and

AFTER DOBSON IN "THE PROCEEDINGS OF ZOOLOG. SOC." BY COURTESY OF THE COUNCIL

FIG. 17.—SUCTIONAL DISCS IN THYROPTERA (A) Side, (B) concave surface of thumb disc, (C) foot, with disc and calcar

body) and has a tail from 65–70 mm. long. A closely allied species, *S. nigrita*, is rather a highly coloured animal, being yellow-brown above and bright golden-yellow below, the body colouration contrasting vividly with the black wings. *Scotomanes ornatus*, another member of the *Vespertilioninae*, is bright orange-buff in colour, with a pure white stripe extending down the back.

(15) The family *Mystacopidae* was founded on a single New Zealand bat, *Mystacops tuberculatus*, related to *Myotis* and *Molossus*.

(16) The family *Molossidae* is common to the warmer parts of both the New and Old World; in these bats the double articulation of the shoulder-joint is perfected, and the wing-membrane markedly reduced in size. There are 13 or 14 genera; *Cheiromeles*, from the Malay peninsula and East Indies, is one of the most interesting genera, containing but a single species, *C. torquatus*; it is a very large, ugly bat (head and body 135 mm.; tail 45 mm.; hindfoot 30 mm.). The upper surface of the body appears quite naked and the wing membrane is greatly reduced in size. In *Eumops* the ears are very large; some of the species are a fair size (head and body 160–90 mm. in length) and very dark in colour. *Molossus* is closely allied; these bats are a small size (head and body about 60 mm.) and in some the body is speckled, owing to the light hair-bases showing through the dark tips. The genus *Tadarida* now accommodates the *Nyctinomus*-like bats of India and Africa; the free-tailed bats of South America and Australia alone being considered as true *Nyctinomus*. One of the most handsome species of this group is *Atomops wroughtoni*, from India, a dark chocolate-coloured bat with a light collar-like

(9) Family *Desmodontidae*. This family is composed of the well-known blood-sucking vampire bats. Their teeth are specially adapted for cutting rather than crushing; the whole anatomy of these bats being specially modified for obtaining a diet of blood. They are found only in the warmer parts of America, as far north as southern Mexico. Dental formulae $I_2^2, C_1^1, P_3^3, M_1^1$ (*Desmodus* and *Diaemus*); $I_2^2, C_1^1, P_3^3, M_2^2$ (*Diphylla*). The bats of the genus *Diaemus* are of striking appearance, the body being brown in colour and the wings black with white margins. The best-known and most specialised genus of the family is *Desmodus*; it seems probable that these bats are unable to take any other food than blood. See VAMPIRE.

(10) Family *Natalidae*. A group of small bats from America as far north as Mexico. Dental formula: $I_2^2, C_1^1, P_3^3, M_3^3$.

(11) Family *Furipteridae*. A South American family, allied to *Natalidae*, with a dental formula of $I_2^2, C_1^1, P_3^3, M_3^3$.

(12) Family *Thyropteridae*, closely related to the *Natalidae*, distinguished by the form of the sternum, separate lumbar verte-

marking just in front of the shoulders; this bat is of fair size:—head and body 88 mm.; tail 40 mm.; ear 33 mm. The genus *Chaerephon* (Africa, Asia and Australia) contains mostly small-sized bats, one of them, *C. limbatus*, having pure white wings. *Xiphonycteris*, *Eomops*, *Platymops*, *Molossops*, *Mormopterus*, and *Promops* are other genera belonging to this group.

EXTINCT BATS

Several of the earlier extinct species appear to be related to the Rhinolophidae. Remains of Pteropodidae belonging to existing genera have been found in the warmer parts of the eastern hemisphere; and an extinct generic type, *Archaeopteropus*, has been obtained from the Miocene lignite of Italy, which appears to be transitional between the typical fruit-bats and the insectivorous bats. Of the Oligocene forms *Pseudorhinolophus* of Europe is apparently a member of the Rhinolophidae; but the affinities of *Alastor* and *Vespertiliavus*, which are likewise European, are more doubtful. The North American *Vespertilio anemophilus* and the European *V. aquensis* and *V. parisensis* are, on the other hand, members of the Vespertilionidae.

BIBLIOGRAPHY.—H. Winge, *Jordfundne og nulevende Flagermus (Chiroptera)* (Copenhagen, 1892), contains much valuable information; and for the Pteropodidae, P. Matschie, *Megachiroptera* (Berlin, 1899) and K. Andersen, *British Museum Catalogue*, vol. i., *Megachiroptera* should be consulted. For the rest the student must refer to numerous papers by G. M. Allen, K. Andersen, F. A. Jentink, G. S. Miller, T. S. Palmer, A. G. Rehn, O. Thomas and others, chief amongst which is "The Families and Genera of Bats," *U.S. Nat. Mus. Bull.* (1907) by G. S. Miller. (J. G. D.)

CHIRU, a graceful Tibetan antelope (*Pantholopus hodgsoni*), of which the bucks are armed with long, slender and heavily ridged horns of a peculiar type. Chiru are very wary and difficult to approach; they are generally found in small parties. They inhabit the desolate plateau of Tibet, at elevations of between 13,000 and 18,000ft., and have a thick coat, formed of close woolly hair of a grey-fawn colour. The most peculiar feature about the chiru is its swollen, puffy nose, probably connected with breathing a rarefied atmosphere. The chiru is allied to the saiga (q.v.).

CHIRURGEON, one whose profession it is to cure disease by operating with the hand. The word in its original form is now obsolete. It derives from the Mid. Eng. *cirurgien* or *sirurgien*, through the Fr. from the Gr. words meaning *hand* and *work*; from the early form is derived the modern word "surgeon." "Chirurgeon" is a 16th century reversion to the Greek origin. (See SURGERY.)

CHISEL, a sharp-edged tool for cutting metal, wood or stone. There are numerous varieties of chisels used in different trades; the carpenter's chisel is wooden-handled with a straight edge, transverse to the axis and bevelled on one side; stone masons' chisels are bevelled on both sides, and others have oblique concave or convex edges. A chisel with a semicircular blade is called a "gouge." The tool is worked either by hand-pressure or by blows from a hammer or mallet. The "cold chisel" has a steel edge, highly tempered to cut unheated metal. The derivation is from O.Fr. *cisel*, modern *ciseau*, late Lat. *cisellum*, a cutting tool, from *caedere*, to cut. (See TOOL.)

CHISHOLM, HUGH (1866–1924), editor of the *Encyclopædia Britannica*, was born in London on Feb. 22, 1866. He was

of Scottish descent, the son of Henry Chisholm, who became warden of the standards in the Board of Trade. Educated at Felsted school and Corpus Christi college, Oxford, of which he was a scholar, he graduated in 1888 with a first class in *literæ humaniores*. He then read for the bar, being called at the Middle Temple in 1892, but occupied himself also with occasional journalism and finally adopted that profession. From 1892 to 1897 he was assistant editor, and from 1897 to the end of 1899 editor, of the *St. James's Gazette*, and during these years he also contributed numerous articles on political, financial and literary subjects to the weekly journals and monthly reviews, becoming known as a literary critic and Conservative publicist.

On resigning the editorship of the *St. James's*, he became a leader writer for *The Standard*, and later, in 1900, was invited to join *The Times*, under whose management he acted as the responsible co-editor, with Sir Donald Mackenzie Wallace and President A. T. Hadley of Yale university, of the new volumes, constituting the tenth edition (1902), of the *Encyclopædia Britannica*, becoming in 1903 editor-in-chief of the 11th edition. Throughout his editorship he worked in close co-operation with Horace Everett Hooper, publisher of the *Encyclopædia Britannica*, and manager of its sales and publicity. The alliance between the two men, based on mutual respect and confidence, was a very close one and productive of happy results, H. E. Hooper supplying the business ability and Hugh Chisholm the scholarship. Under his editorship the 11th edition of the *Britannica* appeared in 1910–11.

Rejoining *The Times* in 1913 as day editor, he became financial editor at the end of that year, and occupied this responsible position all through the momentous period of the World War, resigning his connection with *The Times* in March 1920, in order to reassume the editorship of the *Encyclopædia Britannica* and to organize the publication of the new volumes constituting the 12th edition.

As editor of the *Encyclopædia Britannica* Chisholm displayed remarkable ability. His gift for organization, combined with his wide range of knowledge, enabled him to scheme out a subject, or an article, sometimes better than the expert whom he was inviting to write on it. He had an unusual power of visualizing the right arrangement of details, and his letters to contributors, written always in his own hand, were practically a synopsis of the contents of the *Encyclopædia*. In politics he was a tariff reformer with clear and definite views. In literature, his taste was catholic and his judgment sound. As financial editor of *The Times*, Chisholm displayed great courage and remarkable quickness in grasping the financial situation. Bringing a fresh mind to bear upon the intricacies of the money market, he wrote with lucidity and authority, and contributed in no small degree to the maintenance of a high standard in financial journalism. His point of view was always that of a true patriot, and both privately and publicly he rendered very valuable services to the State in connection with the raising of the various war loans.

He died in London on Sept. 29, 1924. In 1893 Chisholm married E. Beatrix Harrison, of Ardkeen, County Down, Ireland, and had three sons. (J. E. C.)

CHISHOLM, a mining village of St. Louis county, Minnesota, U.S.A., on the Mesabi iron range, 75m. N.W. of Duluth. It is served by the Duluth, Missabe and Northern and the Great Northern railways. The population was 9,039 in 1920, of whom 3,412 were foreign-born white, and was 8,308 in 1930 by the Federal census. The village was settled about 1901.

CHISLEHURST, an urban district of Kent, England, 11½m. S.E. of London, by the S.R. Pop. (1931) 9,876. It is 300ft. above sea-level on a spur of the North Downs in the midst of a common of furze and heather. The church of St. Nicholas (Perpendicular with Early English portions, much restored) has a tomb of the Walsingham family, who had a lease of the manor from Elizabeth. The mortuary chapel attached to the Roman Catholic church of St. Mary was built to receive the body of Napoleon III., who died at Camden Place in 1873. This house was built by William Camden, the antiquary, in 1609, and in 1765 gave the title of Baron Camden to Lord Chancellor Pratt. It was the

CHISELS IN COMMON USE FOR CUTTING METAL, STONE OR WOOD USED IN CARPENTRY AND OTHER TRADES

residence of Napoleon III., of the empress Eugénie and of the prince imperial.

CHISWICK, an urban district of Middlesex, England, and western suburb of London, on the Thames, $7\frac{1}{2}$ m. W. by S. of St. Paul's cathedral. Pop. with Brentford (1931) 62,617. Chiswick House, formerly a seat of the duke of Devonshire, was bought in 1928 by the district council.

The church of St. Nicholas has ancient portions. In the churchyard is the tomb of William Hogarth. Chiswick Hall, no longer extant, was formerly associated with Westminster school. Here in 1811 the Chiswick Press was founded by Charles Whittingham. The parish and urban district include Turnham Green, Gunnersbury and Grove Park. The district is semi-residential; there are breweries and river-side works. Off Chiswick lies Chiswick Eytot.

CHITA, a county, town and river in the Far Eastern area of the Russian Socialist Federal Soviet Republic. The area of the county is 181,039 sq. km. and its population (1926) 380,000, urban 65,032 and rural 314,968. It consists of the south-western tongue of the Far Eastern area lying between Mongolia and the Buriat Mongol S.S.R., and is thus a plateau area, with the south-western portion of the Yablonoi mountains rising above the plateau. An island of territory on the south-eastern slopes of the Yablonoi mountains, extending to the left bank of the Onon river, and crossed by the railway from Chita to Manchuria, belongs to the Buriat Mongol S.S.R. The sub-alpine conditions and the extreme continental character of the climate are unfavourable to agriculture except along the valleys of the Shilka and its tributaries the Ingoda and Onon. Rye is the main crop, though oats, wheat, buckwheat, barley, grass and potatoes are also grown. Herding of horses, cattle, sheep and goats is, however, more important than cultivation, and only .9% of the county is ploughed land. But the essential wealth of the county is in its forests and minerals. Timber and fur (especially fox and squirrel) are exported, the latter being sent to the Irbit and Nijni Novgorod fairs. The mineral wealth of the county is very great, gold is produced in quantity and 5,400 men were working in the gold mines in 1923-24. Brown coal is mined, and used mainly for the railway and for the town of Chita, and iron ore is mined in quantity. It is almost the only area in U.S.S.R. where wolfram, bismuth and molybdenum are found. There are tin mines near the Onon river and precious stones, e.g., crystal, topaz, aquamarine, amethyst, tourmaline and beryls occur, but are not exploited at present. Mining in the area ceased during the civil war following the 1917 revolution, but most of the mines were working again in 1925. Much of the rolling stock of the railway was destroyed in this period and great damage done to the permanent way, and this hampered the reorganization of the mining industry. Manufactures are little developed, the chief being metal goods and leather. A few electric stations exist. The district is noted for contraband trade with Manchuria and Mongolia.

The town of Chita, lat. 52° N., long. $113^{\circ} 25'$ E. Pop. (1926) 57,731, is on the Chita river above its confluence with the Ingoda. With the coming of the Trans-Siberian railway and the increasing exploitation of the mineral, timber and fur wealth of the county, the population and importance of the town have greatly developed. Its industries include iron-founding, fur and leather dressing, soap-boiling, chemical works and box-making. The Russian Geographical society has a museum in the town. The Dekabrist, exiled after the December 1825 plot, by their improvements in draining and levelling, converted Chita from a village to a prosperous settlement.

CHITALDROOG, a district and town in the native state of Mysore, India. The district has an area of 4,022 sq. m. and a population (1921) of 574,179. The rainfall is low, and the Vedavati or Hagari river, in whose valley the town lies, is mostly dry in the hot season. Several parallel chains of hills, reaching an extreme height of 3,800 ft., cross the district; otherwise it is a plain. The chief crops are cotton and rice, and manganese is worked. The west of the district is served by the Madras and Southern Mahratta railway. The largest town in the district is Davangere with cotton factories and a trade in cotton and grain. The town of Chitaldroog, which is the district headquarters (pop.

1921, 8,520) has a considerable trade in cotton. It possesses massive fortifications erected under Hyder Ali and Tippoo Sahib towards the close of the 18th century; and near it on the west are remains of a city of the 2nd century A.D. It is the terminus of a railway from Chikjajur.

CHITARRONE: see LUTE, THEORBO.

CHITON, a genus of Amphineura (*q.v.*). (See also MOL-LUSCA.)

CHITRAL, a native state in the North-West Frontier Province of India. The State of Chitral (see also HINDU KUSH) is somewhat larger than Wales, and supports a population of about 35,000 rough, hardy hillmen. Both the state and its capital are called Chitral, the latter being situated about 47 m. from the main watershed of the range of the Hindu Kush, which divides the waters flowing down to India from those which take their way into the Oxus. The state is important because of its situation at the extremity of the country over which the government of India exerts its influence, and for some years before 1895 it had been the object of the policy of the government of India to secure an effective guardianship over its northern passes. This policy resulted in a British agency being established at Gilgit (Kashmir territory). Chitral can be reached either by the long circuitous route from Gilgit, involving 200 m. of hill roads and the passage of the Shandur pass (12,250 ft.), or (more directly) from the Peshawar frontier at Malakand by 100 m. of route through the independent territories of Swat and Bajour, involving the passage of the Lowarai (10,450 ft.). It is held by a small force as a British outpost.

The district of Chitral is called Kashgar by the people of the country. It was under Chinese domination in the middle of the 18th century, and was a Buddhist centre of some importance in the early centuries of our era. The aboriginal population is probably to be recognized in the people called Kho (speaking a language called Khowar), who form the majority of its inhabitants. Upon the Kho a people called Ronas have been superimposed, who form the chief caste and fighting race of the Chitral districts, who originally came from the north, but have adopted the language and fashions of the conquered Chitrali. (X.)

The Siege of Chitral.—The town of Chitral (pop. in 1901, 8,128), is chiefly famous for a siege which it sustained in the spring of 1895. Owing to complications arising from the demarcation of the boundary of Afghanistan which was being carried out at that time, and the ambitious projects of Umra Khan, chief of Jandol, who was a tool in the hands of Sher Afzul, a political refugee from Chitral supported by the amir at Kabul, the mehtar (or ruler) of Chitral was murdered, and a small British and Sikh garrison subsequently besieged in the fort. A large force of Afghan troops was at that time in the Chitral river valley to the south of Chitral, nominally holding the Kafirs in check during the progress of boundary demarcation. It is considered probable that some of them assisted the Chitralis in the siege. The position of the political agent Dr. Robertson (afterwards Sir George Robertson) and his military force of 543 men (of whom 137 were non-combatants) was at one time critical. Two forces were organized for the relief. One was under Sir R. Low, with 15,000 men, who advanced by way of the Malakand pass, the Swat river and Dir. The other, which was the first to reach Chitral, was under Colonel Kelly, commanding the 32nd Pioneers, who was placed in command of all the troops in the Gilgit district, numbering about 600 all told, with two guns, and instructed to advance by the Shandur pass and Mastuj. This force encountered great difficulties owing to the deep snow on the pass (12,230 ft. high), but it easily defeated the Chitrali force opposed to it and relieved Chitral on April 20, the siege having begun on March 4. Sher Afzul, who had joined Umra Khan, surrendered, and eventually Chitral was restored to British political control as a dependency of Kashmir. See Sir George Robertson, *Chitral* (1898). (T. H. H.)

CHITTAGONG, town and port of British India, giving its name to a district and division of Bengal. It is situated on the right bank of the Karnaphuli river, about 12 m. from its mouth. It is the terminus of the Assam-Bengal railway and a port of call for the Clan line of steamers. The municipal area covers about

98q.m.; pop. (1921) 36,030. Tea is brought from Assam for export to Europe; mineral oil comes in bulk from Burma, is put into tins here and distributed by rail; other exports are jute, raw cotton, rice and hides.

The District of Chittagong occupies a strip of coast and hills between the Bay of Bengal and the mountains. Its area is 2,497sq.m.; in 1921 the population was 1,611,422. A few unimportant ranges rise within the north-eastern portion, the highest hill being the sacred Sitakund, 1,155ft. high. The principal rivers are the Karnaphuli, on which Chittagong town is situated, navigable by sea-going ships as far as Chittagong port, the Halda and the Sangu. The wild animals include tigers, elephants, leopards and deer. The northern portion of the district is traversed by the Assam-Bengal railway. Tea cultivation is moderately successful; there were 21 gardens with an output of 1,250,000lb. in 1921. Chittagong was a famous sea-port known to the Portuguese as Porto Grande, and described by de Barros in 1552 as "the most famous and wealthy city of the kingdom of Bengal"; it has been generally identified with the City of Bengala mentioned by Portuguese and other writers. Conquered by the Mohammedans in the 14th century, it passed under the rule of the Arakanese in the next century. The piratical raids of the Arakanese and their Portuguese mercenaries led to the despatch of a strong force by Shaista Khan, the Mughal Nawab of Bengal, which in 1666 captured the town and occupied the district. The Portuguese also had a settlement at Dianga, where 600 of them were massacred by the Arakanese in 1607. Chittagong was ceded to the East India company by Nawab Mir Kasim Ali in 1760.

The Chittagong Hill Tracts is an independent district occupying the hill country between Chittagong proper and the Lushai hills. The highest point is 4,034ft. above sea-level. Its area covers 5,138sq.m.; pop. (1921) 173,243. The inhabitants are either descendants of Arakanese or aboriginal tribes, such as Maghs, Tipperas and Chakmas: seven-tenths are Buddhists. The Hill Tracts are grouped in three circles, each under a chief, who is responsible for the collection of revenue and the internal management of the villages. The headquarters are at Rangamati, which was wrecked by a cyclone in October, 1897.

The Division of Chittagong lies at the north-east corner of the Bay of Bengal, extending northward along the left bank of the Meghna. It consists of the districts of Chittagong, the Hill Tracts, Noakhali and Tippera. Its area covers 11,710sq.m.; the population in 1921 was 6,000,524.

CHITTOOR, a town and district of the Madras Presidency, British India. The district which has an area of 5,611 sq.m. and a population (1921) of 1,269,157, was formed in recent years from the northern part of North Arcot. It is in great part hilly, being traversed by spurs of the Eastern Ghats radiating east and south. The surface in the hill-country is rocky, save for patches of stunted jungle, but the narrow valleys between the hills are fertile, and the hills themselves are highly mineralized, showing copper and iron especially. The chief crops are rice, millet and oil-seeds. Chittoor (pop. 1921, 17,941) is the chief town, with a station on the Madras and South Mahratta railway, 100 m. by road from Madras. It contains a native college, mission training school, a hospital and a sanatorium. There is a trade in granite, a distillery and a tannery, but Chittoor is not an important centre. Hyder Ali died here in 1782.

CHITTY, SIR JOSEPH WILLIAM (1828–1899), English judge, was born in London. He was the second son of Thomas Chitty, a celebrated special pleader and writer of legal text-books. Joseph Chitty was educated at Eton and Balliol college, Oxford, and elected to a fellowship at Exeter college. He became a member of Lincoln's Inn in 1851, was called to the bar in 1856, and made a queen's counsel in 1874, electing to practise in the court of the Master of the Rolls, Sir George Jessel, before whom he was very successful. In 1880 he entered the house of commons as Liberal member for Oxford (city); in 1881, however, he was selected to fill the vacancy in the chancery division caused by the elevation of the master of the rolls to the court of appeal by the Judicature Act. In 1897 he was promoted to the court of appeal.

See E. Manson, *Builders of our Law* (1904).

CHIUSI, a town of Tuscany, Italy, province of Siena, 55m. S.E. by rail from the town of Siena, and 26m. N.N.W. of Orvieto by the main line from Rome to Florence. Pop. 2,307 (town), 6,746 (commune). The ancient name was Clusium (*q.v.*). It is on a hill 1,305ft. above sea-level, and is surrounded by mediaeval walls, in which, in places, fragments of the Etruscan wall are incorporated. The cathedral of S. Secondiano is a basilica with eighteen ancient marble columns. It has fine choir books from Monte Oliveto Maggiore (*see* ASCIANO). Chiusi was devastated by malaria in the middle ages (*see* CHIARA). Nine miles by road to the north-west are the baths of Chianciano with important springs (which are especially valuable for liver troubles) and several hotels.

CHIVALRY, the knightly class of feudal times. (*See* KNIGHTHOOD AND CHIVALRY.) The primary sense in the middle ages is "knights" or "fully armed and mounted fighting men." Thence the term came to mean that gallantry and honour expected of knights. Lastly, the word came to be used in its general sense of "courtesy." In English law chivalry meant the tenure of land by knights' service. The *Court of Chivalry* was a court instituted by Edward III., of which the lord high constable and earl marshal of England were joint judges, having summary criminal jurisdiction as regards all offences of knights, and generally as to military matters. When the earl marshal alone presided it was a court of honour deciding as to precedence, coats of arms, etc. This court sat for the last time in 1737. The heraldic side of its duties is now vested in the earl marshal as head of the Herald's College.

CHIVASSO, a town and episcopal see of Piedmont, Italy, province of Turin, 18m. N.E. by rail from that town, 600ft. above sea-level. Pop. (1921) 5,359 (town); 10,932 (commune). It is on the left bank of the Po, near the influx of the Orco. The cathedral (15th century) has a fine façade, with statues in terracotta. A tower remains of the old castle of the marquesses of Monferrato, who possessed the town from 1164 to 1435. It was an important fortress in the middle ages and until the French dismantled it (1804). Chivasso, on the main line from Turin to Milan, is the junction of branches for Aosta, Asti, and Casale Monferrato.

CHIVE (*Allium Schoenoprasum*), a hardy perennial plant, with small narrow bulbs tufted on short root-stocks and long cylindrical hollow leaves. It is found in the north of England and in Cornwall, and growing in rocky pastures throughout temperate and northern and in the mountain districts of southern Europe and in Asiatic Russia. It is cultivated for its leaves, which are used in salads and soups as a substitute for young onions; it will grow in any good soil.

CHLADNI, ERNST FLORENS FRIEDRICH (1756–1827), German physicist, was born at Wittenberg, on Nov. 30, 1756. He was educated in law but left it to study science after the death of his father. Inspired by the works of Euler and Bernoulli, Chladni became a pioneer in experimental sound. He investigated the torsional vibrations of rods and the longitudinal vibrations of strings and rods applying the latter to the determination of the velocity of sound in solids. Chladni measured the velocity of sound in gases other than air by filling an organ pipe with the gas and measuring the pitch of the note emitted. His observations on vibrating plates are well known, and the dust figures formed at the nodes of such plates are called "Chladni's Figures." In 1809 he exhibited his "figures" to the French Institute; the demonstration was so warmly received that he showed them to Napoleon who gave Chladni 6,000 francs so that his book *Die Akustik* (1802) might be translated into French. In order to earn his living Chladni travelled in Germany, France and Italy giving scientific lectures and performing on an instrument designed and constructed by himself which he called a euphonium. He died at Breslau on April 3, 1827, leaving his money to the poor box of his native town and his collection of meteorites to the royal collection in Berlin.

Chladni was the author of a number of papers in the *Berlin Monthly Musical Notes*, of *Neue Entdeckungen über die Theorie des Klanges* (1787) and *Neue Beiträge zur Akustik* (1817).

CHLOPICKI, GREGORZ JOZEF (1772-1854), Polish general, was born in Podolia. In 1787 he enlisted in the Polish army and fought in the campaigns of 1792-94. He served with the new Italian legion at the storming of Peschiera, at Modena, Busano, Casabianca and Ponto, and in 1807 commanded the first Vistula regiment. In Spain he obtained the Legion of Honour for his heroism at Epila and the storming of Saragossa. Chlopicki accompanied the Grande Armée into Russia (1812). On the reconstruction of the Polish army in 1813 he was made a general of a division, afterwards joining the Russian army with the rank of general officer. He held aloof at first from the Polish national rising of 1830, but at the request of his countrymen he accepted the dictatorship on Dec. 5, 1830. Lacking faith in the success of the movement, he clung to the hope of negotiation with Russia and acted purely on the defensive. On Jan. 17, 1831, he resigned and became a private, until he was forced to retire into private life owing to serious wounds received at Olszyna.

See Josef Maczynski, *Life and Death of Joseph Chlopicki* (Pol.) (Cracow, 1858); Ignacy Pradzynski, *The Four Last Polish Commanders* (Pol.) (Posen, 1865).

CHLORAL or **TRICHLOROACETALDEHYDE**, first prepared by J. von Liebig in 1832, is a heavy, oily and colourless liquid, of specific gravity 1.541 at 0°C, boiling point 97.7°C and the formula CCl_3CHO . It has a greasy, somewhat bitter taste, and gives off a vapour at ordinary temperature which has a pungent odour and an irritating effect on the eyes. The word *chloral* is derived from the first syllables of *chlorine* and *alcohol*, the names of the substances employed for its preparation. Chloral is soluble in alcohol and ether, in less than its own weight of water, and in four times its weight of chloroform. It deliquesces in the air, and is converted by water into a hydrate, with evolution of heat; it combines with alcohols and mercaptans. With an alkali, chloral gives chloroform (*q.v.*) and a formate; oxidizing agents give trichloroacetic acid, $\text{CCl}_3\text{CO}_2\text{H}$. When kept for some days, as also when placed in contact with sulphuric acid or a very small quantity of water, chloral undergoes spontaneous change into the polymeride metachloral $(\text{C}_2\text{Cl}_4\text{OH})_n$, a white substance slowly volatile in the air, and reconverted into chloral without melting at 180°C.

Chloral is prepared by passing dry chlorine into cooled absolute alcohol; towards the end of the operation the liquid is heated nearly to boiling. The alcohol is converted finally into a syrupy fluid, from which chloral is procured by treatment with sulphuric acid (P. Fritsch, 1894). The crude chloral is distilled over lime, and is purified by further treatment with sulphuric acid, and by redistillation. A mixture of starch or sugar with manganese peroxide and hydrochloric acid may be employed instead of alcohol and chlorine (A. Staedeler, 1847).

Chloral hydrate, $\text{CCl}_3\text{CH}(\text{OH})_2$, forms oblique rhombic prisms, perfectly transparent and only slightly odorous. The melting point of pure chloral hydrate is 57°, the boiling point 96-98°C. When heated with sulphuric acid it is converted into anhydrous chloral and *chloralide*, $\text{C}_2\text{H}_2\text{Cl}_4\text{O}_2$. When mixed with water, chloral hydrate causes a considerable degree of cold; and, as with camphor, small fragments of it placed on the surface of water exhibit gyratory movements. Chloral hydrate does not restore the colour to a solution of fuchsine decolorized by sulphurous acid; this absence of aldehydic property indicates that the water present is combined in the molecular condition. Chloral may be estimated by distilling the hydrate with milk of lime and measuring the volume of chloroform produced, or by hydrolysis with a known volume of standard alkali and back titration with standard acid. Chloral hydrate has the property of checking the decomposition of many albuminous substances, such as milk and meat; and a mixture with glycerin, according to J. Personne, is suitable for the preservation of anatomical preparations.

Pharmacology and Therapeutics.—The alkaline hydrolysis (*q.v.*) of chloral hydrate, with production of chloroform and formates, led Liebreich to the conjecture that a similar decomposition might be produced in the blood; and hence his introduction of the drug in 1869, as an anaesthetic and hypnotic. It is now known, however, that the drug circulates in the blood unchanged, and is excreted as urochloralic acid. The dose is often given in the

form of the pharmacopoeial *Syrupus Chloral*, which contains ten grains of chloral hydrate to the fluid drachm. In large doses chloral hydrate is a depressant to the circulation and the respiration, and also lowers the temperature. In the above dosage the drug is a powerful and safe hypnotic, acting directly on the brain, and producing no preliminary stage of excitement. About 20 minutes after taking such a dose, the patient falls into a refreshing sleep which, lasting several hours, is not distinguishable from natural sleep and is without disagreeable after-symptoms. Chloral hydrate rapidly induces a depression of the anterior horns of grey matter in the spinal cord, and as strychnine poisoning is accompanied by violent stimulation of these areas, chloral hydrate is a valuable antidote in such cases. It should not be hypodermically injected. Its disadvantages are that it is powerless when there is pain, resembling in this feature nearly all hypnotics except opium (morphine) and hyoscin. Its action on the spinal cord has been employed with success in cases of tetanus, whooping-cough, urinary incontinence and strychnine poisoning. In the latter case 20 grains in "normal saline" solution may be directly injected into a subcutaneous vein, but not into the subcutaneous tissues.

Toxicology.—In cases of acute poisoning by chloral hydrate, the symptoms may be summarized as those of profound coma. The treatment is to give a stimulant emetic such as mustard; to keep up the temperature by hot bottles, etc.; to prevent or disturb the patient's morbid sleep by the injection of hot strong coffee into the rectum, and by shouting, flipping with towels, etc.; to use artificial respiration in extreme cases. Strychnine injections are much less likely to save life after poisoning by chloral hydrate, than chloral hydrate is to save life in poisoning by strychnine.

Habitual use of chloral as a drug results in chronic poisoning. The victim is usually excited, loquacious, easily fatigued and suffers from attacks of readily induced syncope. The patient may succumb to a dose only slightly larger than usual. There is no specific remedy; the patient must be persuaded to put himself under restraint, and the drug must be stopped at once and entirely.

CHLORATES, the metallic salts of chloric acid; they are all solids, soluble in water, the least soluble being the potassium salt. They may be prepared by dissolving or suspending a metallic oxide or hydroxide in water, saturating the hot solution with chlorine; by double decomposition; or by neutralizing a solution of chloric acid by a metallic oxide, hydroxide or carbonate. They are all decomposed on heating, with evolution of oxygen; and in contact with concentrated sulphuric acid with liberation of chlorine peroxide. The most important is potassium chlorate, KClO_3 , which was obtained in 1786 by C. L. Berthollet by the action of chlorine on caustic potash, and this method was at first used for its manufacture. The modern process consists in the electrolysis of a hot solution of potassium chloride, or, preferably, the formation of sodium chlorate by the electrolytic method and its subsequent decomposition by potassium chloride. (See **ALKALI MANUFACTURE**.) Potassium chlorate crystallizes in large white tablets, of a bright lustre. It melts without decomposition, and begins to give off oxygen at about 370°C. By very careful regulation this decomposition can be made to yield the perchlorate, KClO_4 . The decomposition is rendered more easy and regular by mixing the salt with powdered manganese dioxide. The salt finds application in the preparation of oxygen as an oxidizing agent in the laboratory, with concentrated hydrochloric acid in the laboratory production of chlorine, in the manufacture of matches, for pyrotechnic purposes, and in medicine. If crystals of potassium chlorate are rubbed together in the dark, they become faintly luminous; this phenomenon is known as "triboluminescence." Sodium chlorate, NaClO_3 , is prepared by the electrolytic process; by passing chlorine into milk of lime and decomposing the calcium chlorate formed by sodium sulphate; or by the action of chlorine on sodium carbonate at low temperature (not above 35°C.). It is much more soluble in water than the potassium salt. Its crystal structure resembles that of calcite; sodium atoms occur at alternate corners of a rhombohedron, and the other corners are occupied by chlorine atoms each surrounded by three co-planar oxygen atoms.

Potassium chlorate is very valuable in medicine. Given in large

doses it causes rapid and characteristic poisoning, with alterations in the blood and rapid degeneration of nearly all the internal organs; but in small doses—5 to 15 grains—it partly undergoes reduction in the blood and tissues, the chloride being formed and oxygen being supplied to the body cells in nascent form. Its special uses are in ulceration of the mouth or tongue (*ulcerative stomatitis*), tonsillitis and pharyngitis. For these conditions it is administered in the form of a lozenge, but may also be swallowed in solution, as it is excreted by the saliva and so reaches the diseased surface. Its remarkable efficacy in healing ulcers of the mouth—for which it is the specific—has been ascribed to the production of chloric acid, which, being an extremely powerful antiseptic, kills the bacteria to which the ulcers are due.

CHLORINE, a gaseous chemical element of the halogen group, taking its name from the colour, greenish-yellow (Gr. *χλωρός*); symbol Cl, atomic number 17, atomic weight 35.457, isotopes 35, 37. It was discovered in 1774 by Scheele, who called it *dephlogisticated muriatic acid*; about 1785, C. L. Berthollet, regarding it as being a compound of hydrochloric acid and oxygen, termed it *oxygenized muriatic acid*. This view was generally held until about 1810–11, when Sir H. Davy showed definitely that it was an element, and gave it the name which it now bears.

Chlorine is never found in nature in the uncombined condition, but in combination with the alkali metals it occurs widely distributed in the form of rock-salt (sodium chloride); as sylvine and carnallite, at Stassfurt; and to a smaller extent in various other minerals such as matlockite and horn-mercury. In the form of alkaline chlorides it is found in sea-water and various spring waters, and in the tissues of animals and plants; while, as hydrochloric acid it is found in volcanic gases.

The preparation of chlorine on the small scale depends on the oxidation of hydrochloric acid; the usual oxidizing agent is manganese dioxide, which, when heated with concentrated hydrochloric acid, forms manganese chloride, water and chlorine:— $\text{MnO}_2 + 4\text{HCl} = \text{MnCl}_2 + 2\text{H}_2\text{O} + \text{Cl}_2$. The manganese dioxide may be replaced by various other substances, such as red lead, lead dioxide, potassium bichromate, and potassium permanganate. Instead of heating hydrochloric acid with manganese dioxide, use is frequently made of a mixture of common salt and manganese dioxide, to which concentrated sulphuric acid is added and the mixture is then heated:— $\text{MnO}_2 + 2\text{NaCl} + 3\text{H}_2\text{SO}_4 = \text{MnSO}_4 + 2\text{NaHSO}_4 + 2\text{H}_2\text{O} + \text{Cl}_2$. (For electrolytic and other industrial methods of preparation, see CHLORINE: *In Industry*.)

Chlorine is a gas of a greenish-yellow colour, and possesses a characteristic unpleasant and suffocating smell. It can be liquefied at -34°C under atmospheric pressure, and at -102°C it solidifies and crystallizes. Its specific heat at constant pressure is 0.1155, and at constant volume 0.08731, and its refractive index 1.000772, whilst in the liquid condition the refractive index is 1.367. The density is 2.4885 (air=1). Its critical temperature is 146°C and its critical pressure 93.5 atm.; it is not appreciably dissociated at 1500°C , but at 2350°C 50% of the molecules are broken down to atoms. Liquid and solid chlorine are both yellow in colour. The gas must be collected either by downward displacement, since it is soluble in water and also attacks mercury; or over a saturated salt solution, in which it is only slightly soluble. At ordinary temperatures it unites directly with many other elements; thus with hydrogen, combination takes place in direct sunlight with explosive violence; arsenic, antimony, thin copper foil and phosphorus take fire in an atmosphere of chlorine, forming the corresponding chlorides. Many compounds containing hydrogen are readily decomposed by the gas; for example, a piece of paper dipped in turpentine inflames in an atmosphere of chlorine, producing hydrochloric acid and a copious deposit of soot; a lighted taper burns in chlorine with a dull smoky flame. The solution of chlorine in water, when freshly prepared, possesses a yellow colour, but on keeping becomes colourless, on account of its decomposition into hydrochloric acid and oxygen. It is on this property that its bleaching and disinfecting power depends (see BLEACHING). Water saturated with chlorine at 0°C deposits crystals of a hydrate $\text{Cl}_2 \cdot 8\text{H}_2\text{O}$, which is readily decomposed at a higher temperature into its constituents. Chlorine hydrate has an historical importance, as by

sealing it up in a bent tube, and heating the end containing the hydrate, whilst the other limb of the tube was enclosed in a freezing mixture, M. Faraday was able to obtain liquid chlorine.

Chlorine finds an extensive use in organic chemistry as a substituting and oxidizing agent, as well as for the preparation of addition compounds. For purposes of substitution, the free element, as a rule, only works slowly on saturated compounds, but the reaction may be accelerated by the action of sunlight or on warming, or by using a "carrier." In these latter cases the reaction may proceed in different directions; thus, with the aromatic hydrocarbons, chlorine in the cold or in the presence of a carrier substitutes in the benzene nucleus, but in the presence of sunlight or on warming, substitution takes place in the side chain. Iodine, antimony trichloride, molybdenum pentachloride, ferric chloride, ferric oxide, antimony, tin, stannic oxide and ferrous sulphate have all been used as chlorine carriers.

Hydrochloric Acid.—Chlorine combines with hydrogen to form hydrochloric acid, HCl, the only known compound of these two elements. The acid itself was first obtained by J. R. Glauber in about 1648, but J. Priestley in 1772 was the first to isolate it in the gaseous condition, and Sir H. Davy in 1810 showed that it contained hydrogen and chlorine only, as up to that time it was considered to contain oxygen. It may be prepared by the direct union of its constituents, and with the displacement of the Leblanc soda process by the ammonia-soda and electrolytic-soda processes the production of synthetic hydrochloric acid has acquired industrial importance. On the large scale and also for the preparation of small quantities it is made by the decomposition of salt by means of concentrated sulphuric acid, $\text{NaCl} + \text{H}_2\text{SO}_4 = \text{NaHSO}_4 + \text{HCl}$. (See ALKALI MANUFACTURE.) The commercial acid is usually yellow in colour and contains many impurities, such as traces of arsenic, sulphuric acid, chlorine, ferric chloride and sulphurous acid.

It is a colourless gas, which can be condensed by cold and pressure to a liquid boiling at -83.7°C , and can also be solidified, the solid melting at -112.5°C . Its critical temperature is 52.3°C , and its critical pressure is 86 atmospheres. The gas fumes strongly in moist air, and it is rapidly dissolved by water, one volume of water at 0°C absorbing 503 volumes of the gas. The gas does not obey Henry's law, that is, its solubility in water is not proportional to its pressure. It is one of the "strong" acids, being ionized to the extent of about 91.4% in decinormal solution according to conductivity and cryoscopic methods (see SOLUTION). The strongest aqueous solution of hydrochloric acid at 15°C contains 42.9% of the acid, and has a specific gravity of 1.212. On being boiled at ordinary pressure, solutions stronger than 20.24% lose HCl, and weaker solutions lose water until a mixture of this composition is obtained; this boils constantly at 110° and has a specific gravity of 1.10, but it is not a definite hydrate because its composition is slightly different if it is produced by evaporation at higher or lower pressures. Perfectly dry hydrochloric acid gas has no action on metals, but in aqueous solution it dissolves many of them with evolution of hydrogen and formation of chlorides.

Chlorides.—The salts of hydrochloric acid, known as *chlorides*, can, in most cases, be prepared by dissolving either the metal, its hydroxide, oxide, or carbonate in the acid; or by heating the metal in a current of chlorine, or by precipitation. The majority of the metallic chlorides are solids (stannic chloride, titanous chloride and antimony pentachloride are liquids) which readily volatilize on heating. Many are readily soluble in water, the chief exceptions being silver chloride, mercurous chloride, cuprous chloride and palladium chloride which are insoluble in water, and thallous chloride and lead chloride which are only slightly soluble in cold water, but are readily soluble in hot water. Bismuth and antimony chlorides are decomposed by water with production of oxychlorides, whilst titanium tetrachloride yields titanous acid under the same conditions. All the metallic chlorides, with the exception of those of the alkali and alkaline earth metals, are reduced either to the metallic condition or to that of a lower chloride on heating in a current of hydrogen; most are decomposed by concentrated sulphuric acid. They can be distinguished from the corresponding bromides and iodides by the fact that on distillation with a mix-

ture of potassium bichromate and concentrated sulphuric acid they yield chromium oxychloride, whereas bromides and iodides by the same treatment give bromine and iodine respectively. Some metallic chlorides readily form double chlorides, the most important of these double salts being the platinichlorides (chloroplatinates) of the alkali metals. The chlorides of the non-metallic elements are usually volatile fuming liquids of low boiling-point, which can be distilled without decomposition and are decomposed by water. Hydrochloric acid and its metallic salts can be recognized by the formation of insoluble silver chloride, on adding silver nitrate to their nitric acid solution, and also by the formation of chromium oxychloride (*see above*). Chlorides can be estimated quantitatively by conversion into silver chloride, or if in the form of alkaline chlorides (in the absence of other metals, and of any free acids) by titration with standard silver nitrate solution, using potassium chromate as an indicator (*q.v.*).

Oxides.—Chlorine and oxygen do not combine directly, but compounds can be obtained indirectly. Three oxides are known: chlorine monoxide, Cl_2O , chlorine peroxide, ClO_2 , and chlorine heptoxide, Cl_2O_7 .

Chlorine monoxide results on passing chlorine over dry precipitated mercuric oxide at 0°C . It is a pale yellow gas which can be condensed, on cooling, to a dark-coloured liquid boiling at 19°C . It is extremely unstable, decomposing with extreme violence on the slightest shock or disturbance, or on exposure to sunlight. It is readily soluble in water, with which it combines to form hypochlorous acid. Sulphur, phosphorus, carbon compounds, and the alkali metals react violently with the gas, taking fire with explosive decomposition.

Chlorine peroxide was first obtained by Sir H. Davy in 1815 by the action of concentrated sulphuric acid on potassium chlorate: $3\text{KClO}_3 + 2\text{H}_2\text{SO}_4 = \text{KClO}_4 + 2\text{KHSO}_4 + \text{H}_2\text{O} + \text{ClO}_2$. A mixture of chlorine peroxide and chlorine (which Davy called "euchlorine") is obtained by the action of hydrochloric acid on potassium chlorate, and similarly, on warming a mixture of potassium chlorate and oxalic acid to 70°C on the water bath, a mixture of chlorine peroxide and carbon dioxide is obtained. Chlorine peroxide must be collected by displacement, as it is soluble in water and readily attacks mercury. It is a heavy gas of a deep yellow colour and possesses an unpleasant smell. It can be liquefied, the liquid boiling at 9.9°C , and on further cooling it solidifies to orange crystals at -79°C . It is highly explosive, being resolved into its constituents by influence of light, by warming, or by shock. It is a very powerful oxidant; a mixture of potassium chlorate and sugar spontaneously inflames when touched with a drop of concentrated sulphuric acid or even on rubbing, the chlorine peroxide liberated setting fire to the sugar, which goes on burning.

Chlorine heptoxide was obtained by A. Michael (1900, 1901) by slowly adding perchloric acid to phosphoric oxide below -10°C ; the mixture is allowed to stand for a day and then gently warmed, when the oxide distils over as a colourless very volatile oil of boiling-point 82°C . It turns to a greenish-yellow colour in two or three days and gives off a greenish gas; it explodes violently on percussion or in contact with a flame, and is gradually converted into perchloric acid by the action of water. On the addition of iodine to this oxide, chlorine is liberated and a white substance is produced, which decomposes, on heating to 380°C , into iodine and oxygen; bromine is without action.

Oxy-acids.—Several oxy-acids of chlorine are known, namely, hypochlorous acid, HClO , chlorous acid, HClO_2 , chloric acid, HClO_3 , and perchloric acid, HClO_4 . Hypochlorous acid is formed when chlorine monoxide dissolves in water, and can be prepared (in dilute solution) by passing chlorine through water containing precipitated mercuric oxide in suspension, or best by passing carbon dioxide through a suspension of bleaching powder in water. Precipitated calcium carbonate may be used in place of the mercuric oxide, or a hypochlorite may be decomposed by a dilute mineral acid and the resulting solution distilled under diminished pressure. For this purpose a filtered solution of bleaching-powder and a very dilute solution of nitric acid may be employed. The acid is only known in aqueous solution, and only dilute solutions can be distilled without decomposition. The solution has a pale

yellow colour, and is a strong oxidizing and bleaching agent; it is readily decomposed by hydrochloric acid, with evolution of oxygen. The salts of this acid are known as hypochlorites, and like the acid itself are very unstable, so that it is almost impossible to obtain them pure. A solution of sodium hypochlorite (*Eau de Javelle*), which can be prepared by passing chlorine into a cold aqueous solution of caustic soda, has been extensively used for bleaching purposes. One of the most important derivatives of hypochlorous acid is bleaching powder. Sodium hypochlorite can be prepared by the electrolysis of brine solution in the presence of carbon electrodes, having no diaphragm in the electrolytic cell, and mixing the anode and cathode products by agitating the liquid. The temperature should be kept at about 15°C , and the concentration of the hypochlorite produced must not be allowed to become too great, in order to prevent reduction taking place at the cathode. Its solutions are used in preservatives and antiseptics, but on keeping or warming they decompose to chloride and chlorate.

Chlorous acid has been prepared in solution by adding sulphuric acid in theoretical proportion to a solution of the barium salt; its solutions readily decompose to hypochlorous and chloric acids. The sodium salt is prepared by the action of sodium peroxide on a solution of chlorine peroxide: $2\text{ClO}_2 + \text{Na}_2\text{O}_2 = 2\text{NaClO}_2 + \text{O}_2$. The silver and lead salts are unstable, being decomposed with explosive violence at 100°C . On adding a caustic alkali solution to one of chlorine peroxide, a mixture of a chlorite and a chlorate is obtained.

Chloric acid was discovered in 1786 by C. L. Berthollet, and is best prepared by decomposing barium chlorate with the calculated amount of dilute sulphuric acid. The aqueous solution can be concentrated *in vacuo* over sulphuric acid until it contains 40% of chloric acid. Further concentration leads to decomposition, with evolution of oxygen and formation of perchloric acid. The concentrated solution is a powerful oxidizing agent; organic matter being oxidized so rapidly that it frequently inflames. Hydrochloric acid, sulphuretted hydrogen and sulphurous acid are rapidly oxidized by chloric acid. The salts of this acid are known as chlorates (*q.v.*).

Perchloric acid is best prepared by distilling potassium perchlorate with concentrated sulphuric acid under diminished pressure. Perchloric acid distils over at first, but if the distillation be continued a white crystalline mass of hydrated perchloric acid, $\text{HClO}_4 \cdot \text{H}_2\text{O}$, passes over; this is due to the decomposition of some of the acid into water and lower oxides of chlorine, the water produced then combining with the pure acid to produce the hydrated form (H. E. Roscoe). This solid, on redistillation, gives the pure acid, which is a liquid boiling at 39°C (under a pressure of 56mm.), melting at -112°C , and of specific gravity

$1.764 \frac{22^\circ}{4}$. The crystalline hydrate melts at 50°C . A constant-boiling solution (b.p. 203°C under 760mm. pressure) of 71.6% content results as in the case of hydrochloric acid (*see above*). The pure acid decomposes slowly on standing, but is stable in dilute aqueous solution. It is a very powerful oxidizing agent; wood and paper in contact with the acid inflame with explosive violence. In contact with the skin it produces painful wounds. It may be distinguished from chloric acid by the fact that it does not give chlorine peroxide when treated with concentrated sulphuric acid, and that it is not reduced by sulphurous acid. The salts of the acid are known as the *perchlorates*, and are all soluble in water; the potassium and rubidium salts, however, are only soluble to a slight extent, and methods for the estimation of these metals are based on this fact. Potassium perchlorate, KClO_4 , can be obtained by carefully heating the chlorate until it first melts and then nearly all solidifies again. The fused mass is then extracted with water to remove potassium chloride, and warmed with hydrochloric acid to remove unaltered chlorate, and finally extracted with water again, when a residue of practically pure perchlorate is obtained. The alkaline perchlorates are isomorphous with the corresponding permanganates.

IN INDUSTRY

As an industrial product of increasing importance chlorine is closely connected with alkali and the manufacturing industries

are, in practice, combined. It has been pointed out in another article (*see* ALKALI) that the manufacture of chlorine has undergone a complete revolution in recent years. During the ascendancy of the Le Blanc soda process, it was necessary to produce chlorine in order to reduce the great surplus of unwanted hydrochloric acid, which served as the raw material. Nowadays the reverse is the case, and the production of caustic soda, by the

FIG. 1.—PRINCIPLES OF A MERCURY CELL

Mercury enters the cell at one end, propelled by a mechanical device. Brine flows through the cell in the same direction as the mercury (entrance and exit not shown). The mercury-sodium amalgam formed by the electrolysis leaves the cell and travels to a separate chamber in which it is brought into contact with water. After extraction of the sodium, the mercury returns to the cell and repeats the cycle

electrolytic process, is limited by the extent to which the accompanying chlorine can be utilized.

Chemically speaking, chlorine can be produced in several ways; *i.e.*, from hydrochloric acid with the aid of "oxidizing" agents; from salt by the action of sulphuric acid and an oxidizing agent combined; or by the so-called "electrolytic method," in which an electric current is passed through a solution of common salt in water. The two former methods are now obsolete; the Deacon and Weldon processes were examples of the oxidation of hydrochloric acid, and ceased to be operated when the Le Blanc soda process was finally superseded by Solvay's ammonia-soda method. The electrolytic process is the source of all the chlorine now produced on the large scale. The action of the electric current on brine is to produce chlorine gas, hydrogen gas and a solution of caustic soda simultaneously. The caustic soda is concentrated and solidified; the hydrogen is either allowed to go to waste or is used for the synthesis of ammonia (with nitrogen) or of hydrochloric acid (with chlorine); the chlorine gas is piped off and utilized for making either liquid chlorine, in which there is now a large trade; bleaching powder; hydrochloric acid; calcium and sodium hypochlorites; sulphur-chlorine compounds; chlorinated organic compounds; or metallic chlorides.

The raw materials of the industry are salt and coal; the former as the actual source of the chlorine, and the latter to provide the energy for removing it from its combination with the sodium. The industry therefore tends to concentrate in districts where brine is available, and where cheap energy exists, either as coal or water-power. Where water-power is to be had it may prove economical to site the works there and bring salt from a distance. In general, and as in the case of alkali, the chlorine industry is one in which it is cheaper to build the plant close to the raw materials rather than close to the markets in which the products are to be sold.

England, Germany and North America are the chief producing countries, and Italy is developing rapidly. In the two former countries the industry has long been well-established, but in Canada and the United States, with their great deposits of salt, and unrivalled sources of cheap water-power, it is comparatively of recent development; it has nevertheless already reached such dimensions that practically the whole of the requirements of these countries can now be satisfied without imports. Of recent years Italy also has gone ahead in this matter, largely owing to the rise of the artificial silk industry there; this requires large quantities of caustic soda which, taken together with a well-organized system of water-power, provides a good basis for electrolytic chlorine-soda manufacture.

England and Germany are the chief exporting countries. The total production of chlorine and chlorine compounds amounts to

300,000 tons per annum. The largest chlorine manufacturing plant in 1928 was situated at South Charleston, W.Va., with a capacity of one hundred tons per day.

Manufacture of Chlorine.—The electrolytic process is nowadays the only source of chlorine on a large scale. It is nevertheless of interest, both from a historical as well as a chemical point of view, to give some account of the older methods.

C. W. Scheele, who discovered chlorine in 1774, made use of manganese dioxide, in the form of the natural mineral pyrolusite, to oxidize hydrochloric acid:—

This reaction must be promoted by heating the mixture, although even then only a part of the hydrochloric acid is oxidized. Owing to strongly corrosive action of both hydrochloric acid and moist chlorine, no metal could be employed in the construction of vessels, which were made of stone slabs. The process was very costly, as much of the acid and all the manganese was wasted, and the waste liquor from the vessels was of a most noxious kind.

The chemistry of the process is not quite so simple as the foregoing description indicates, but sufficient has been said to give a general outline of it. Of the hydrochloric acid originally employed only some 35% is actually converted to chlorine, the remainder being lost as calcium chloride.

The second well-known process, due to Henry Deacon working from 1868 onwards, is also based on the oxidation of hydrochloric acid, but using atmospheric air in place of manganese dioxide. Deacon worked on the direct reaction

This reaction is under ordinary circumstances so slow as to be quite useless for practical purposes. If, however, a "catalyst" is employed at the proper temperature, the process proceeds at a very much greater rate, and can even be carried out as a continuous operation.

The catalyst that Deacon used was cupric chloride: if pieces of porous clay be soaked in a solution of this salt, dried, and heated to about 450° C. and the temperature maintained there or slightly higher, they are found to have the property of producing chlorine and water continuously from a stream of mixed hydrochloric acid gas and air passed over them. On a large scale about 60% of the acid can thus be decomposed. The air-acid mixture was taken directly from the pan in which salt cake (*q.v.*) had been prepared, after cooling to condense out water and reheating to the temperature necessary for the catalytic reaction.

The Electrolytic Method.—The Deacon process made cheaper chlorine than the Weldon process: but it is evident that in both cases the plant was complicated, costly and difficult to manipulate. The contrast between these older methods and the modern electrolytic process is very marked.

The various types of plant employed nowadays all depend upon the decomposition of the molecules of salt by means of the applied energy of the electric current. Faraday discovered that equal quantities of electric energy will liberate elements from their compounds in amounts proportional to their equivalent weights: for example, 23 grams of sodium, 35.5 grams of chlorine, 107 grams of silver, 31.5 grams of copper, are all set free from solutions of their salts, or from the fused salts, under appropriate conditions by the same quantity of electric energy, *viz.*, 96,540 coulombs. The degree to which this decomposition is brought about is a function solely of the amount of electric energy applied, and does not depend on the voltage, or electrical pressure. At the same time, owing to considerations which cannot be enlarged upon here, it is found that a certain minimum voltage is required before actual liberation of the elements takes place; the voltage actually used in practice depends upon the type of "cell" in which the electrolysis is conducted, and may vary from 3.5 to 7 volts.

A very large number of cells have been devised to work this process; but, neglecting the Acker process, which used fused sodium chloride, only three principal types are now in use; *viz.*,

the mercury cell, the diaphragm cell and the "belljar" cell.

In each of these types a solution of sodium chloride (brine) is used; the points at which the electric current is introduced into the solution are called respectively the "anode" and "cathode."

The mercury cell (fig. 1) has the form of a rectangular horizontal box; saturated brine, *i.e.*, brine containing as much salt as possible, is fed into the cell at one end and overflows in the partially spent condition at the other. Into this brine dip anodes of graphitic carbon; on the bottom of the cell is a layer of mercury which forms the cathode. The action of the current liberates chlorine upon the graphite anodes in the form of a gas, which is conveyed away by pipes for subsequent use; at the cathode sodium is deposited and at once forms an amalgam with the mercury. This amalgam is caused to flow into another compartment, where it is brought into contact with water, the effect of which is to extract the sodium with formation of a dilute solution of caustic soda and hydrogen gas; the disposal of the latter has already been touched upon. After the removal of the sodium the mercury returns to the first compartment. This type of cell, which is now largely employed, was devised by Castner in the United States, and by Kellner in Austria. In the original form the movement of the mercury was occasioned by rocking the cell on a pivot; in more modern plant the mercury is propelled by mechanical means, the cell itself being stationary. The alkali thus produced is of high purity, and the "current efficiency" or yield per unit of current good; but the plant is expensive to erect and the mercury costly.

The diaphragm type of cell (fig. 2) uses no mercury which can be moved from one compartment to another, and it is therefore necessary to provide some means whereby the sodium and the chlorine may be collected separately.

To effect this, the cell, which, in the form chosen for description here, takes the shape of a cylinder on end, is divided into two annular compartments by a ring or diaphragm of asbestos fibre, supported by a perforated metal sheet or wire screen on the outer side. This iron gauze forms the cathode at which the sodium separates. The anode is formed by graphitic carbon sticks suspended from the top of the cell and hanging vertically in the inner compartment of the cell. This compartment is fed with purified brine. Purification of the brine from the calcium and magnesium compounds, which occur naturally in it, is necessary on account of the subsequent blocking and deterioration of the asbestos diaphragm which would otherwise occur: the purification is carried out by precipitating the calcium as carbonate and the magnesium as hydroxide by treatment with sodium carbonate and caustic soda. As the asbestos diaphragm is permeable to liquid some brine runs through it, so that the metal sheet on the outside is continually wet. On passing the current through the cell, chlorine is liberated at the anode as in the mercury cell, and sodium momentarily at the metal cathode, where it at once reacts with the water of the brine which has soaked through the asbestos, and forms a solution of caustic soda, with simultaneous evolution of hydrogen gas. The liquor thus formed contains a large proportion of undecomposed salt, which is recovered in solid form during the subsequent evaporation for the production of solid caustic soda. Not only does this cause some complication in the method adopted for evaporation, but the resulting caustic soda cannot be obtained free from salt, and contains usually about 2% of it.

In the Belljar type (fig. 3) the anode is surrounded by an in-

FIG. 2.—DIAGRAM OF A CYLINDRICAL DIAPHRAGM CELL.

The sodium set free at the perforated cathode reacts with the brine, which percolates through it, forming caustic soda and hydrogen gas. The chlorine is set free at the carbon anodes.

verted bell of material, which does not conduct electricity, placed in a tank in which the cathode is suspended. Brine is fed into the interior of the bell and the chlorine there produced is piped off as before. The caustic soda formed at the cathode sinks, by virtue of its greater density, through the brine and is drawn off through a pipe. The liquor produced is similar to that formed in the diaphragm process.

Various modifications and combinations of these main types of cell exist. The bulk of the electrolytic chlorine produced to-day is made in the mercury and diaphragm cells, the relative advantages of which are as follows: In the mercury cell the preliminary treatment of the brine is much cheaper; the liquid produced in the cell is much more concentrated, and it contains no salt, so that evaporation is a straight-forward operation. In the diaphragm cell the capital cost of the installation is less, as no expensive mercury is required; the consumption of electric energy is less per unit of product, and salt of high purity can be produced as a by-product if required. The choice of process for any given purpose depends, therefore, on a variety of considerations, and must be made on the merits of each individual case.

Liquid Chlorine.—The chlorine from the cell is now usually liquefied by subjecting it to refrigeration with, or without, pressure, and is packed in steel cylinders or tank waggons. Before this can be done, however, it is necessary to dry it thoroughly; this is accomplished by bringing it into contact with concentrated sulphuric acid. Chlorine that contains moisture has the property of attacking metals; chlorine in the absence of water does not do this, and can therefore be packed safely in steel vessels, provided that the latter are strong enough to withstand the pressure necessary to keep the chlorine in the liquid condition under all conditions of atmospheric temperature which are likely to be met with. This liquid chlorine is the form in which the element is now most largely employed.

USES OF CHLORINE

In the days of the Weldon and Deacon processes the principal outlet for chlorine was in the manufacture of bleaching powder (*q.v.*). Although a very considerable quantity of this is now produced, its place has been taken to a great extent by liquid chlorine itself. Chlorine has an immediate and disastrous effect on all forms of low organic life, and is therefore an ideal disinfectant. The quantity required, for example, to sterilize potable water, or swimming pools, completely is extremely minute and, when

FIG. 3.—THE BELLJAR CELL

The anode is here separated from the cathode by an inverted bell non-conductive of electricity. Brine enters the interior of the bell and the chlorine produced is piped off.

the treatment is properly carried out, no taste can be detected. Over 75% of the drinking water of North America is sterilized with chlorine. The death rate from typhoid has dropped from 28 per 100,000 in 1908 to less than five per 100,000 in 1927, and much of this improvement can be traced to the use of chlorine. This, and the application to sewage, is daily finding more extended use. Chlorine in the form of hypochlorite is the potent ingredient of the familiar Carrel-Dakin solution and other types of germicides. It is frequently found that metal surfaces, such as condenser tubes, which are in constant contact with water, de-

velop considerable growths of algae and similar vegetable matter, which impair the efficiency of the apparatus. These growths can be entirely inhibited by the addition of very small quantities of chlorine to the water, and the efficiency of the plant restored to the normal.

The biggest outlet for chlorine is the pulp and paper trade. As is well-known, modern newsprint and paper of the inferior sorts

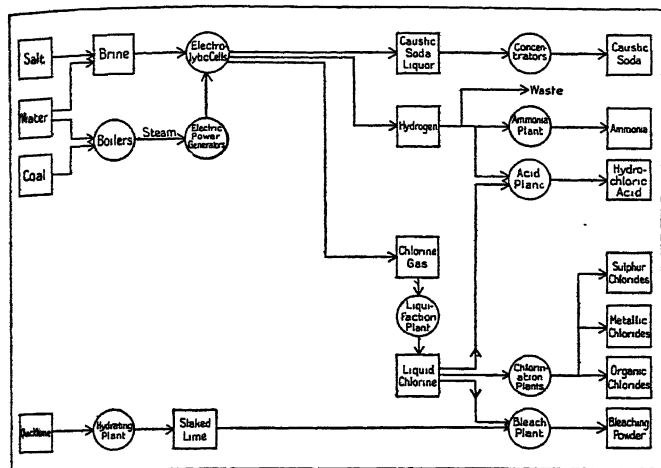

FIG. 4.—THE MANUFACTURE OF CHLORINE AND ITS DERIVATIVES

The diagram shows, from left to right, the manufacture of chlorine from salt, water, and coal, the principal industrial compounds formed, and the commercial utilization of the by-products

generally are made from wood which has been shredded and beaten to a pulp. This requires bleaching before it can be used as paper and to this is due the rise of the chlorine industry in North America. Bleaching powder (*q.v.*) was at one time extensively used for this purpose, and is still to some extent; but in Canada and the United States the change over to chlorine itself is very marked, and the same tendency is showing itself to an increasing degree in Europe.

In the manufacture of artificial silk large quantities of chlorine are involved. In the viscose process the source of cellulose is, generally, wood pulp which, as mentioned above, is bleached by chlorine. Caustic soda is also used and the pure product of the mercury cell is much preferred. In the acetate process liquid chlorine and sulphur-chlorine compounds are required. The rise of the artificial silk trade has, therefore, been very beneficial to the industry in general.

Sodium and calcium hypochlorites, prepared by action of chlorine on caustic soda and lime respectively, are also used as bleaching agents.

Both liquid chlorine and bleaching powder are used in large amounts in the refining of crude natural oils.

The organic chemical industry provides an important outlet for chlorine in the manufacture of dyestuffs, insecticides, fire-extinguishing liquids, grease-removers, solvents of different kinds, anaesthetics (chloroform), and various intermediate compounds used in comparatively small quantities throughout the chemical industry. Chlorine is widely used in bleaching flour.

In metallurgy chlorine has been used for the extraction of metals from their ores.

Even from the above abbreviated description of the industry, it will readily be seen that chlorine, like so many other raw materials of the modern world, is one of those products which, without being obtrusive, and, in fact, without being known even by name to the vast majority of people, yet has a profound influence on our daily life. Newspapers, clothes, medicines, colours, sanitation and petrol, for example, are matters of concern to everyone, and all consume chlorine or its derivatives at some stage. In 1774, when first discovered by Scheele, it was a chemical curiosity masquerading under the name of "dephlogisticated marine acid air"; it is now a necessity.

CHLORITE, a group of green micaceous minerals which are hydrous silicates of aluminium, magnesium and ferrous iron. The name was given by A. G. Werner in 1798, from *χλωρίτης*, "a green stone." Several species and many rather ill-defined varieties have been described, but they are difficult to recognize. Like the micas, the chlorites (or "hydromicas") are monoclinic in crystallization and have a perfect cleavage parallel to the flat face of the scales and plates. The cleavage is, however, not quite so prominent as in the micas, and the cleavage flakes though pliable are not elastic. The chlorites usually occur as soft ($H.=2-3$) scaly aggregates of a dark-green colour. They vary in specific gravity between 2.6 and 3.0, according to the amount of iron present. Well-developed crystals are met with only in the species *clinochlore* and *penninite*; those of the former are six-sided plates and are optically biaxial, whilst those of the latter have the form of acute rhombohedra and are usually optically uniaxial. The species *prochlorite* and *corundophilite* also occur as more or less distinct six-sided plates. These four better crystallized species were grouped together by G. Tschermak as *orthochlorites*, the finely scaly and indistinctly fibrous forms being grouped by the same author as *leptochlorites*.

Chemically, the chlorites are distinguished from the micas by the presence of a considerable amount of water (about 13%) and by not containing alkalis; from the soft, scaly, mineral talc they differ in containing aluminium (about 20%) as an essential constituent. The magnesia (up to 36%) is often in part replaced by ferrous oxide (up to 30%), and the alumina to a lesser extent by ferric oxide; alumina may also be partly replaced by chromic oxide, as in the rose-red varieties kämmererite and kotschubeite:

The chlorites usually occur as alteration products of other minerals, such as pyroxene, amphibole, biotite, garnet, etc., often occurring as pseudomorphs after these, or as earthy material filling cavities in igneous rocks composed of these minerals. Many altered igneous rocks owe their green colour to the presence of secondary chlorite. Chlorite is also an important constituent of many schistose rocks and phyllites, and of chlorite-schist it is the only essential constituent. (L. J. S.)

CHLOROFORM, a valuable anaesthetic first prepared by J. v. Liebig and E. Soubeiran (1831). It is a colourless liquid (trichloromethane, CHCl_3), possessing an agreeable smell and a pleasant taste. It may be prepared by the action of bleaching powder on many carbon compounds, but preferably ethyl alcohol and acetone, by heating trichloroacetic acid with ammonia or by alkaline hydrolysis of chloral (*q.v.*). In the preparation of chloroform by the action of bleaching powder on ethyl alcohol it is probable that the alcohol is first oxidized to acetaldehyde, which is subsequently chlorinated and then decomposed. Chloroform solidifies in the cold and then melts at -62°C. ; it boils at 61.2°C. , and has a specific gravity 1.52637 ($0^\circ \text{C.}/4^\circ \text{C.}$) (T. E. Thorpe). It is an exceedingly good solvent, especially for fats, alkaloids and iodine. It is not inflammable. Chromic acid or exposure to light converts it into phosgene (carbonyl chloride, COCl_2). It reacts with sodium ethylate to form orthoformic ester, $\text{CH}(\text{OC}_2\text{H}_5)_3$. When digested with phenols and caustic soda it forms hydroxyaldehydes (K. Reimer); and when heated with alcoholic potash it is converted into potassium formate.

Chloroform may be readily detected by the production of an isonitrile when it is heated with alcoholic potash and a primary amine; thus with aniline the nauseating odour of phenyl isocyanide is produced.

For the use of chloroform as an anaesthetic, see ANAESTHESIA. Chloroform may be given internally in doses of from one to five drops. The *British Pharmacopœia* contains a watery solution—the *Aqua Chloroformi*—which is useful in disguising the taste of nauseous drugs; a liniment which consists of equal parts of camphor liniment and chloroform, and is a useful counter-irritant;

the *Spiritus Chloroformi* (erroneously known as "chloric ether"), which is a useful anodyne in doses of from five to forty drops; and the *Tinctura Chloroformi et Morphinæ Composita*, which is the equivalent of a proprietary drug called chlorodyne. This tincture contains chloroform, morphine and prussic acid, and must be used with the greatest care.

Externally chloroform is an antiseptic, a local anaesthetic if allowed to evaporate, and a rubefacient, causing the vessels of the skin to dilate, if rubbed in. Its action on the stomach is practically identical with that of alcohol (*q.v.*), though in very much smaller doses. Chloroform is also used as a counter-irritant; as a local anaesthetic for toothache due to caries; an antispasmodic in tetanus and hydrophobia; and as the best and most immediate and effective antidote in cases of strychnine poisoning.

CHLOROPHYLL, CHEMISTRY OF. Chlorophyll is the green colouring matter of leaves and is present in all growing vegetable cells. Unexpectedly, the pigment responsible for the brown colour of certain algae has been found to be identical with the chlorophyll of land plants. We owe our present knowledge of the chemistry of chlorophyll chiefly to Willstätter.

The chloroplasts of all plants have been found to consist of a colloidal mixture of proteins and other substances with four pigments, namely, chlorophyll-*a*, chlorophyll-*b*, an orange red hydrocarbon, $C_{40}H_{56}$, called carotin (also occurring in, and responsible for the colour of, carrots), and a yellow pigment, $C_{40}H_{56}O_2$, called xanthophyll. It is probable that all these substances are of vital importance in the physiology of the plant, and, indeed, the photosynthesis of starch from carbon dioxide does not proceed in the absence of chlorophyll. Fresh leaves contain about 0.2% of chlorophyll-*a*, 0.075% of chlorophyll-*b*, 0.015% of carotin and 0.03% of xanthophyll. In order to obtain crude chlorophyll, dried powdered leaves (best of the stinging nettle) are extracted with ether, and the amorphous chlorophyll so obtained has been found to have the composition $C_{55}H_{72}N_4O_5Mg$. Analytical data, however, do not establish with certainty the true composition of such a complex substance, and in the light of later work (especially the synthesis of aetiophyllin) it may be that the formulae need to be corrected by the addition of one carbon atom. The compositions given here are those employed by Willstätter in describing his experiments. The discovery that magnesium is an essential part of the chlorophyll molecule was an event of outstanding importance and interest; the metal is bound in a complex condition, very much as iron is in the blood pigments. In fact a complex degradation product of the blood pigment can actually be converted into a complex degradation product of chlorophyll by introducing magnesium into the molecule. It is highly significant that chlorophyll and the blood pigment are so closely related.

If alcohol is used instead of ether for the extraction of chlorophyll, the pigment is obtained in a crystalline modification, but interaction with the alcohol has occurred as the result of the intervention of a specific enzyme termed chlorophyllase. Actually the phytol group (*see below*) is replaced by the ethyl group. In 1864 Stokes demonstrated that chlorophyll is a mixture, but it was not until 1912 that the components of the mixture were separated. If a solution of crude chlorophyll in light petroleum is shaken with aqueous methyl alcohol, chlorophyll-*a* remains in the petroleum whereas chlorophyll-*b* is found in the aqueous layer. Both substances may be crystallized ultimately after a tedious series of fractionations. Chlorophyll-*a* is bluish black and gives greenish-blue solution; it contains H₂ more and O less than chlorophyll-*b*, which is a greenish-black substance giving green solutions.

All true chlorophylls, amorphous, and *a* and *b* (material from over 200 sources was investigated) yield on treatment with alcoholic alkalis about 30% of their weight of phytol together with a molecular proportion of methyl alcohol. Phytol is an unsaturated alcohol, $C_{81}H_{131}C(CH_3):C(CH_3).CH_2OH$ or $C_{80}H_{130}OH$, which has not yet been fully investigated but evidently bears some relation to the terpene family. The methyl alcohol and phytol are bound in groups of the form $-CO-OR$ because the chloro-

phylls are converted by this treatment into the chlorophyllins which are carboxylic acids. Thus the constitution of chlorophyll-*a* can be expanded to $(C_{82}H_{130}ON_4Mg)(COOC_{20}H_{39})(COOCH_3)$ and chlorophyllin-*a* is the corresponding dicarboxylic acid. The presence of a third carboxyl group hidden in the form $-CO-N:$ has been detected and the main line of degradation of the chlorophyll molecule has been the step-wise elimination of these carboxyl groups. For this purpose the graded action of alkalis at temperatures up to 240° has been employed, and it is noteworthy that the magnesium-containing complex in the molecule is not decomposed in the course of such treatment. Many of the intermediate products are brilliantly coloured and exhibit intense fluorescence. The action of acids at any stage causes the elimination of magnesium, but this can usually be re-introduced by means of magnesia or magnesium methyl iodide. It would be beyond the scope of this article to give a full account of the degradation of chlorophyll, but the stages from chlorophyll-*a* to aetioporphyryn may be indicated. Alcoholysis and hydrolysis by chlorophyllase yields chlorophyllide-*a* $(C_{82}H_{130}ON_4Mg)(CO_2Me)(CO_2H)$ which with cold alkali gives chlorophyllin-*a* $(C_{82}H_{130}ON_4Mg)(CO_2H)_2$. Alkali at 140°C yields glaucophyllin $(C_{81}H_{128}N_4Mg)(CO_2H)_2$, and at 165°C this in its turn yields the isomeric rhodophyllin. The second carboxyl is eliminated by alkali treatment at 200°C, giving pyrrophyllin $(C_{80}H_{126}N_4Mg).CO_2H$, whilst the last carboxyl group is removed by heating with soda lime in small quantities at a time. The product is aetiophyllin, $C_{81}H_{126}N_4Mg$. Acids acting on this yield aetioporphyryn, $C_{81}H_{126}N_4$, which is identical with the degradation product of the blood pigment haemin. The action of cold alkali and then alkali at 200°C also converts chlorophyll-*b* into pyrrophyllin.

A more intimate knowledge of the constitution of chlorophyll has resulted from the study of the degradation of the derivatives of the colouring matter by reduction with hydriodic acid and phosphonium iodide and by oxidation. The former method gave alkylated pyrroles identical with those obtained similarly from the blood pigment and from bilirubin; the latter method gave such substances as methylethylmaleinimide and haematic acid. Indeed, the chemistry of chlorophyll and of the blood pigments is so closely related that information derived from the study of one of these groups has had repercussions in the other.

A highly remarkable synthesis effected by H. Fischer and J. Klarer in 1926 enables us to make a short cut and deduce a probable expression for the structure of aetioporphyryn. Cryptopyrrole, 2:4-dimethyl-3-ethylpyrrole, is one of the reduction products of the pigments under notice and had been previously synthesized by unambiguous methods. When it is brominated in cold acetic acid solution it gives a substance, $C_{16}H_{20}N_2Br_2$, which is converted into Willstätter's aetioporphyryn by the action of strong sulphuric acid. This seems to prove that aetioporphyryn is $C_{80}H_{126}N_4$ and the interpretation suggested leads to the following constitution for aetioporphyryn:—

The aetioporphyryn was identified with the natural product by a comparison of solubility, crystallographic characters and absorption spectrum. It gives aetiophyllin on treatment with magnesium methyl iodide. This substance is therefore $C_{80}H_{126}N_4Mg$ and the corrected composition of chlorophyll-*a* is accordingly $(C_{82}H_{130}ON_4Mg)(CO_2C_{20}H_{39})(CO_2CH_3)$ or $C_{86}H_{172}N_4O_5Mg$. Chlorophyll-*b* would then be $C_{86}H_{170}N_4O_5Mg$. It is known from the oxidation products that the carboxyl groups are all situated in the ter-

minimal positions of $-\text{CH}_2\text{CH}_3$ groups, that is, in $-\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ groups, but we have no information as to the relative position of the phytol and methyl alcohol residues or as to which of the three carboxyl groups is bound up in the $-\text{CO}-\text{N}-$ structure.

It will be noted, in the degradation of chlorophyll, that one of the carboxyl groups is much more easily eliminated than the other two, and we may well imagine that an unstable progenitor of the pigment contained still one more carboxyl group, so that each $-\text{CH}_2\text{CH}_3$ in aetiophyllin was originally $-\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$. If this were assumed then the suggestive fact emerges that the molecule could have been constructed in nature by the condensation of four identical monohydric alcohol chains with ammonia. Thus chlorophyllin could be the result of reactions summarized in the equation

It becomes evident that chlorophyll is derived in nature from the sugars which it is itself designed to produce through photosynthesis.

Willstätter and Stoll have described their investigations in a monograph "Untersuchungen über Chlorophyll" (Springer, Berlin, 1913). (R. ROB.)

CHLOROPICRIN, product of the distillation of bleaching powder with many nitro-compounds (e.g., picric acid, nitromethane) also prepared by the action of concentrated nitric acid on chloral or chloroform. A. W. von Hofmann (1866) mixed ten parts of bleaching powder into a paste with cold water adding a solution (saturated at 30°C) of one part of picric acid. A violent reaction occurs and chloropicrin (nitrochloroform, trichloronitromethane), $\text{NO}_2\cdot\text{CCl}_3$, distils over, generally without external heating. It is a colourless liquid of boiling-point 112°C , and of specific gravity 1.692. It is almost insoluble in water, but is readily soluble in alcohol; it has a sharp smell, and its vapour powerfully affects the eyes. Chloropicrin has been employed in chemical warfare (*q.v.*) as a lachrymatory, irritant and lethal agent. High concentrations of this chemical cause fatal lung injuries and death may ensue from exposure to its action even at low concentrations.

CHLOROPLAST, the botanical name for that structure in the plant cell which carries the green pigment, chlorophyll (*q.v.*). (See BOTANY; PHOTOSYNTHESIS; PLANTS.)

CHLOROSIS, the botanical term for loss of colour in a plant-organ, a sign of disease; also in medicine, a form of anaemia (see BLOOD: Pathology).

CHMIELNICKI, BOGDAN (c. 1593–1657), hetman of the Cossacks, but a Pole by descent, was born near Chigirin in the Ukraine. He entered the Cossack ranks and was captured by the Turks; during his two years' captivity in Constantinople he learnt Turkish and French. On his return to the Ukraine he lived quietly on his estate until the tyranny of the Polish governor led him to seek justice at Warsaw. After serving with the Cossacks in the Ukraine campaign of 1646, against the Turks, he suffered fresh persecution as a royalist and a Cossack, and he fled to the Cossack settlements on the Lower Dnieper, whence he sent messages to the khan of the Crimea, urging a simultaneous invasion of Poland by the Tatars and Cossacks (1647). On April 11, 1648, at an assembly of the Zaporozhians (see POLAND: History), he declared his intention of fighting the Poles, and was elected *ataman*. As a result of his victories at Zheltaya Vodui and Kruta Balka in May the serfs rose. Throughout the Ukraine the Polish gentry and the Jesuits were hunted down and slain. The rebels swarmed over the palatinates of Volhynia and Podolia, and Chmielnicki routed the Poles at Pildawa (Sept. 23). In June 1649 he entered Kiev, where he permitted the committal of atrocities on the Jews and Roman Catholics. His extravagant demands at the peace congress at Pereyaslavl led to the renewal of war, which was ended by the compact of Zborow. Chmielnicki was recognized as a semi-independent prince of the Ukraine. His attempt to carve a principality for his son out of Moldavia led to the third outbreak of war in 1651. At Beresteczko (July 1, 1651) Chmielnicki was defeated. In 1652 he sent an embassy to the Tsar asking for

Russia's alliance, and in 1654 took an oath of allegiance to him. All hope of an independent Cossack state was thus at an end, though after the Tsar's successful campaign against Poland, Chmielnicki entered into negotiations with Charles X. of Sweden against Alexis. He died on Aug. 7, 1657.

See P. Kulish, *On the Defection of Malo-Russia from Poland* (Rus.) (Moscow, 1890); S. M. Solovev, *History of Russia*, vol. x. (Rus.) (Moscow, 1857, etc.); R. N. Bain, *The First Romanovs*, ch. iii–iv. (1905).

CHOATE, JOSEPH HODGES (1832–1917), American lawyer and diplomat, was born at Salem, Mass., on Jan. 24, 1832. He was the son of Dr. George Choate, a physician of considerable note, and was a nephew of Rufus Choate. After graduating at Harvard college in 1852, and at the law school of Harvard university in 1854, he was admitted to the bar in 1855 and in 1856 began practice in New York city. His success in his profession was immediate, and in 1860 he became junior partner in the firm of Evarts, Southmayd and Choate, the senior partner in which was William M. Evarts. This firm and its successor, Evarts, Choate and Beaman, remained for many years among the leading law firms of New York and of the country, the activities of both being national rather than local. Choate was associated with many of the most famous litigations in American legal history, including the Tilden, A. T. Stewart and Stanford will cases, the Kansas prohibition cases, the Chinese exclusion cases, the Maynard election returns case and the income tax suit. In 1871 he became a member of the "Committee of Seventy" in New York city, which was instrumental in breaking up the "Tweed Ring," and later assisted in the prosecution of the indicted officials. In the retrial of the Gen. Fitz John Porter case he obtained a reversal of the decision of the original court-martial. His greatest reputation was won, perhaps, in cross-examination. In politics he allied himself with the Republican Party on its organization, being a frequent speaker in presidential campaigns, beginning with that of 1856. He never held political office, although he was a candidate for the Republican senatorial nomination against Senator Thomas C. Platt in 1897. In 1894 he was president of the New York Constitutional Convention. He was appointed by President McKinley ambassador to Great Britain to succeed John Hay in 1899, and remained in that position until 1905. In England he won great personal popularity, and accomplished much in fostering the good relations of the two great English-speaking Powers. He was one of the representatives of the United States at the second Peace Congress at The Hague in 1907. Upon the outbreak of the World War he ardently supported the British and Allied cause and severely criticized President Wilson's hesitation to recommend America's immediate co-operation, but shortly before his death retracted his criticism. He was chairman of the mayor's committee in New York for entertaining the British and French commissions in 1917. His death, which took place in New York on May 14, 1917, was hastened by the physical strain of his constant activities in this connection. Among his last works were *Abraham Lincoln and Other Addresses in England* (1910), *American Addresses* (1911) and *The Boyhood and Youth of Joseph Hodges Choate* (1917).

See *The Choate Story Book* (1903); T. G. Strong, *Joseph Choate, New Englander, New Yorker, Lawyer, Ambassador* (1917); *Joseph Choate, a Great Ambassador* (1918); Edward Sandford Martin, *The Life of Joseph H. Choate* (1920); *Arguments and Addresses of Joseph Hodges Choate*, edit. Frederick C. Hicks, with a memorial by Elihu Root (1926).

CHOATE, RUFUS (1799–1859), American lawyer and orator, was born at Ipswich (Mass.), on Oct. 1, 1799. He graduated as valedictorian of his class at Dartmouth college in 1819, was a tutor there in 1819–20, spent a year in the law school of Harvard university, and studied for a like period at Washington, in the office of William Wirt, then attorney general of the United States. He was admitted to the Massachusetts bar in 1823 and practised for five years, during which time he served in the Massachusetts house of representatives (1825–26) and in the State senate (1827). In 1830 he was elected to Congress as a Whig from the Salem district, and in 1832 was re-elected. His career in Congress was marked by a notable speech in defence of a protective tariff.

In 1834, before the completion of his second term, he resigned and established himself in the practice of law in Boston. For several years he devoted himself unremittingly to his profession, but in 1841 succeeded Daniel Webster in the U.S. Senate. Shortly afterwards he delivered one of his most eloquent addresses at the memorial services for President Harrison in Faneuil Hall, Boston. In the Senate he made a series of brilliant speeches on the tariff, the Oregon boundary, in favour of the Fiscal Bank Act, and in opposition to the annexation of Texas. On Webster's re-election to the Senate, Choate resumed (1845) his law practice, which no amount of urging could ever persuade him to abandon for public office, save for a short term as attorney general of Massachusetts in 1853-54. In 1853 he was a member of the State Constitutional Convention. In July 1859 failing health led him to seek rest in a trip to Europe, but he died on the 13th of that month at Halifax, Nova Scotia, where he had been put ashore when it was seen that he probably could not outlive the voyage across the Atlantic. Choate, besides being one of the ablest of American lawyers, was one of the most scholarly of American public men, and his numerous orations and addresses were remarkable for their pure style, their grace and elegance of form, and their wealth of classical allusion.

His *Works* (edited with a memoir by S. G. Brown) were published in 2 vols. in 1862. The *Memoir* was afterwards published separately (1870). See also E. G. Parker's *Reminiscences of Rufus Choate* (1866); E. P. Whipple's *Some Recollections of Rufus Choate* (1879); and the *Albany Law Review* (1877-78).

CHOBE, a large western affluent of the middle Zambezi (*q.v.*). The river was discovered by David Livingstone in 1851, and to him was known as the Chobe. It is also called the Linyante and the Kwando, the last name being that commonly used.

CHOCOAN, an independent linguistic stock of South American Indians, so called from the Chocos, who are the best known of its tribes. At the time of the first appearance of Europeans the Chocoan tribes seem to have held the region in north-western Colombia along the middle and upper Atrato river, together with the rugged mountain area between it and the Cauca, as well as west to the Pacific coast, where they extended from the Gulf of San Miguel south to the mouth of the San Juan river. The area at the mouth of the Atrato appears to have been occupied by tribes of the Cunan stock. The Chocoan tribes were one of the few South American peoples who lived in pile dwellings, as did the Barbacoan tribes, their neighbours on the south. The Chocoan tribes were skilful canoeists, having large canoes which they used in trade. Andagoya in 1522 heard the first rumours of the Inca empire from the coastal tribes of this stock, and from a district called Biru near the mouth of the San Juan the name Peru is supposed to have been derived. The Chocoan tribes survive today in considerable numbers, but are very little known. They were described at the period of the Conquest as a warlike people, living mainly by hunting and fishing and on wild vegetable products. They had an abundance of gold, which they traded with the Chibchan (*q.v.*) tribes to the east. They used poisoned arrows and also the blow-gun, which was of the two-piece type characteristic of the Amazonian tribes. They wore little or no clothing and lived communally in large houses of thatch, set on very high piles or sometimes in trees.

See P. Simon, *Noticias historiales de las Conquistas de Tierra Firme en las Indias Occidentales* (Bogota, 1882); W. Lehmann, *Zentral Amerika* (Berlin, 1920).

CHOCOLATE, a preparation of the cacao bean and sugar, usually flavoured, it is used either as a food or mixed with hot water and milk as a drink. Cocoa, and chocolate for eating, are comparatively modern preparations, whereas drinking chocolate, of a sort, has been known to Europeans since the discovery of America. The original of the modern chocolate was *chocolatl*, a frothy beverage taken cold and held in high esteem in Mexico by the Aztecs. As *chocolatl* apparently consisted simply of the roasted and ground cacao bean flavoured with peppers and other spices, it was both bitter and pungent. The Spaniards greatly improved it by adding sugar, and guarded the secret of its preparation for nearly a century, when it became known in Italy, Germany and France. In 1657 a Frenchman opened a shop in Queen's

Head alley, Bishopsgate street, London, at which solid chocolate for making the beverage could be purchased at 10s. to 15s. a pound. At this price, only the wealthy could afford to drink it; hence the appearance in London, Amsterdam and other European capitals of the fashionable chocolate houses, some of which developed later into famous clubs. About 1700 the English improved chocolate by the addition of milk. The reduction of the cost of the beverage was hampered in Great Britain by the imposition of high import duties on the raw cacao bean, and it was not until 1853, when Gladstone lowered the duty to a uniform rate of 1d. a lb., that chocolate became popular.

Cakes of chocolate are still the accepted material in France from which to prepare a cacao beverage, but elsewhere cocoa powder has for many years been more generally used. (See COCOA.) Whilst the use of chocolate for drinking has declined, the amount of chocolate eaten has greatly increased.

Method of Manufacture.—The cacao beans having been cleaned, roasted and broken, the shell is removed and the pure "nib" is ground to "mass." The methods are exactly those described under COCOA, save that the temperature of roasting is lower. The sugar used may be clear crystalline granulated sugar, powdered sugar, or the so-called "amorphous" sugar prepared from boiling sugar syrup.

Either cacao nib or mass is mixed with the sugar in a melangeur, a revolving pan with granite rollers. The mixture is repeatedly ground in some form of disintegrator or mill. Grinding rolls made of quartz diorite, porcelain or steel, are generally used. An important exception is the use of vertical revolving steel disks in U.S.A. for the production of the cheaper covering chocolates. In grinding and in later stages (*e.g.*, before moulding) it is necessary to add cacao butter to obtain a chocolate of a suitable consistency—the final chocolate containing perhaps 33% cacao nib or mass, 54% sugar and 13% of added cacao butter.

The flavours of modern chocolates are the result not merely of the blend of beans, the choice of vanilla, cinnamon, aniseed or other spice or flavouring, but also of the special processes which they undergo. Many novel machines, the most popular of which are called conches, are used, in which the chocolate is agitated, mixed, ground or heated often for several days, to give a smooth, mellow and finished confection.

The chocolate so obtained is, when warm, an aromatic plastic dough. It remains to mould it in the familiar cakes, bars, disks (croquettes) or small rectangular tablets (Neapolitans). Before moulding, it is necessary to bring the chocolate to a temperature of 90° to 93° F by passing it over warm rolls or other conditioning device. A machine deposits a definite amount into moulds, which then pass over a shaking table. The chocolate spreads out, and any air bubbles rise and break. The moulds pass through a cooling tunnel, and as the chocolate sets, it contracts, coming from the mould clean and bright, with a rich colour, and so hard that it snaps when broken. The final process of covering with tin or aluminium foil and paper, is accomplished by automatic machines.

Chocolate in block form is recognized as a compact and valuable foodstuff. It is not only sold plain, but is combined with other foodstuffs, for example, various nuts and dried fruits. A preparation with milk for making a drinking chocolate was an English invention; much later (1876) M. D. Peter of Vevey, Switzerland, produced milk chocolate for eating, which is a mixture of cacao nib, sugar, cacao butter and milk. In England milk chocolates containing a very high percentage of milk are preferred, a popular make containing 1½ pints of milk (minus its water) per pound of chocolate.

Chocolates or Chocolate-covered Confectionery.—Chocolate is used for covering all manner of confections. It is prepared by the methods outlined above, but more cacao butter is added to make it flow readily. The best work is done by hand: the vanilla crème, caramel, or other confection is laid on a fork and dipped beneath the molten chocolate, and then turned on to a sheet of paper. A mechanical coverer or "enrober" invented in 1903, is much used; in this machine the crèmes move on a woven wire band through a cascade of liquid chocolate. The decoration and boxing of chocolates are light occupations which offer employment

BY COURTESY OF CADBURY BROTHERS, LTD.

STEPS IN THE PREPARATION OF CHOCOLATE

1. Grinding the cacao nib, showing the "mélangeur," in the left foreground, a revolving pan with granite rollers, where the nib is mixed with sugar; and on the right, grinding machines, where cacao butter is added to produce chocolate of a suitable consistency. 2. Covering candy with chocolate. The paste or confection is held on a fork and dipped into a pan of

confectionery are rapidly coming into use, although the best work is done by hand. 3. Roasting machines in which the cacao beans, after being cleaned and sorted, are heated by gas to a temperature of nearly 140° C. The roasted beans pass between rows of serrated cones, which crack and shell them, the shells being carried off by an air blast

for a large number of girls.

Cacao Butter.—Cacao butter (*cf.* COCOA) is a pale golden yellow butter with a brittle fracture and a characteristic fragrance. Whilst a little is used for making high-class cosmetics and lipstick, the great bulk is used in making chocolate covering and milk chocolate. This use of cacao butter makes the cocoa and chocolate industries interdependent. In the joint industries, from 2 lb. of cacao nib and 1 lb. of sugar is obtained roughly 1 lb. of cocoa and 2 lb. of chocolate.

Cacao butter is the most costly vegetable butter of commercial importance. The following are the average wholesale prices per lb. of prime duty-paid English cacao butter for the years 1918–26:

| Year | Price | Year | Price | Year | Price |
|------|---------------------------------|------|---------------------------------|------|---------------------------------|
| | s. d. | | s. d. | | s. d. |
| 1918 | 1 5 ³ / ₄ | 1921 | 1 7 ¹ / ₄ | 1924 | 1 2 ¹ / ₈ |
| 1919 | 2 2 ³ / ₈ | 1922 | 1 7 ³ / ₈ | 1925 | 1 3 ¹ / ₈ |
| 1920 | 2 3 | 1923 | 1 3 ¹ / ₂ | 1926 | 1 3 ¹ / ₈ |

Production of the Cocoa, Sugar and Confectionery Trades.—The following figures taken from the Board of Trade returns relate to 1924. The total number of persons employed in Great Britain in the cocoa, chocolate, sugar confectionery, jam, etc., factories and workshops was 79,496 (53,258 females; 26,238 males). The cost of the material used was £24,092,000 and the total value of the goods made was £41,225,000.

| Manufactured products Great Britain, 1924 | Quantity | Selling value |
|---|-----------|---------------|
| | cwts. | £ |
| Cocoa or chocolate (except chocolate confectionery) | 984,900 | 7,793,000 |
| Chocolate confectionery | 1,467,200 | 12,559,000 |
| Cacao husks and shells | 92,200 | 22,000 |
| Cocoa butter | 77,600 | 487,000 |
| | 2,621,900 | 20,861,000 |

The general facts of the industry are to be found under COCOA and CONFECTIONERY. According to the United States Biennial Census of Manufactures of 1925 the total value of products of manufactures of chocolate and cocoa was \$100,420,000. Of this amount, \$37,415,000 represents the value of 145,404,000 pounds of chocolate (not including chocolate coatings); \$40,188,000 the value of 223,954,000 pounds of chocolate coatings; \$9,170,000 the value of 78,398,000 pounds of powdered cocoa; \$10,760,000 the value of 38,044,000 pounds of cocoa butter; and \$2,886,000 the value of other products, chiefly chocolate and cocoa specialties. In the 58 reporting establishments there were 7,018 wage earners, who received \$7,861,000 in wages. During the calendar year ending Dec. 31, 1925 the United States imported 382,019,264 pounds of raw cocoa, valued at \$38,246,157; of prepared cocoa (not including confectionery) 5,089,162 pounds, valued at \$1,165,896. (*See* Cocoa Production and Trade, Dept. of Com. and Labor, Washington, D.C., 1912.)

Home-made Chocolates.—A simple recipe is as follows: Take 2 lb. covering chocolate and 4 oz. unsweetened chocolate, cut very small and put in aluminium pan over very slow heat. Stir till smooth. Stand the pan in cold water, and stir until the chocolate thickens. Replace over gentle heat and beat well for 20 minutes.

BIBLIOGRAPHY.—*See* for cacao cultivation: J. H. Hart, *Cacao* (1911) and C. J. J. van Hall, *Cocoa* (1914). For chemistry and manufacture *see*: R. Whymer, *Cocoa and Chocolate* (1921). A popular work on cultivation and manufacture is A. W. Knapp, *Cocoa and Chocolate* (1920). On p. 191–203 of this will be found a full bibliography. (A. W. KN.)

CHOCTAW, a prominent tribe in southern Mississippi, of Muskogee stock (*q.v.*). They farmed intensively and flattened their heads. They were allies of the French, enemies of the British and of most of their Muskogean kinsmen. In the later 18th century they began drifting west of the Mississippi river, and about 1832 the majority moved to what is now eastern Oklahoma, where they remained self-governing and semi-civilized until their absorption into American citizenship in 1906. They number about 18,000 exclusive of negro freedmen included in the "nation," but

include many of mixed blood; the original population seems to have been about the same in size.

CHODKIEWICZ, JAN KAROL (1560–1621), Polish general. In 1599 he was appointed *starosta* of Samogitia, and in 1600 acting commander-in-chief of Lithuania. In the war against Sweden for the possession of Livonia he repulsed the duke of Sudermania, afterwards Charles IX., from Riga, and in 1604 captured Dorpat. At Kirkholm (Aug. 27, 1605) he annihilated a large Swedish army; but he was hampered always by the Polish diet which denied him adequate supplies, and after helping to defeat the rebels in Poland and to relieve Riga when the Swedes again invaded Livonia, he was sent against Moscow with an army which mutinied for lack of pay and was compelled to retreat to Smolensk. On being reinforced by Prince Wladislaus, however, he took the fortress of Drohobu in 1617, and on the conclusion of the Muscovite war by the treaty of Deulina he was sent to defend the southern frontier against the Turks. He died on Sept. 24, 1621, after he had forced the Ottoman army under the Sultan Osman, to raise the siege of Khotin.

See Adam Stanislaw Naruszewicz, *Life of J. K. Chodkiewicz* (Pol.) 4th ed. (Cracow, 1857–58); Lukasz Golebiowski, *The Moral Side of J. K. Chodkiewicz as indicated by his Letters* (Pol.) (Warsaw, 1854).

CHODOWIECKI, DANIEL NICOLAS (1726–1801), German genre painter and engraver of Polish descent, was born at Danzig on Oct. 13 1726, and died at Berlin on Feb. 7 1801. Left an orphan at an early age, he devoted himself to the practice of miniature painting, the elements of which his father had taught him, as a means of support for himself and his mother. From 1754 onwards he studied drawing and painting under Bernhard Rode, and began engraving in 1758. After designing and engraving several subjects from the story of the Seven Years' War, Chodowiecki produced the famous "History of the Life of Jesus Christ," a set of admirably painted miniatures, which made him at once so popular that he laid aside all occupations save those of painting and engraving. Few books were published in Prussia for some years without plate or vignette by Chodowiecki. It is not surprising, therefore, that the catalogue of his works (Berlin, 1814) should include over 3,000 items, the most famous being the picture of "Jean Calas and his Family." He became director of the Berlin Academy in 1797. The title of the German Hogarth was disclaimed by Chodowiecki himself. The illustrator of Lavater's *Essays on Physiognomy*, the painter of the "Hunt the Slipper" in the Berlin Museum, had indeed but one point in common with the great Englishman—the practice of representing actual life and manners.

His brother GOTTFRIED (1728–1781) and son WILHELM (1765–1803) painted and engraved after the style of Daniel, and sometimes co-operated with him. *See* Von Oettingen, *Daniel Chodowiecki* (1895).

CHOERILUS. (1) An Athenian tragic poet, who exhibited plays as early as 524 B.C. He was said to have competed with Aeschylus, Pratinas, and even Sophocles. According to F. G. Welcker, however, the rival of Sophocles was a son of Choerilus, who bore the same name. Suidas states that Choerilus wrote 150 tragedies and gained the prize 13 times. His works are all lost; only Pausanias (i.14) mentions a play by him entitled *Alope*. Choerilus was also said to have introduced considerable improvements in theatrical masks and costumes.

See A. Nauck, *Tragicorum Graecorum Fragmenta* (1889); F. G. Welcker, *Die griechischen Tragödien*, pp. 18, 892.

(2) An epic poet of Samos, who flourished at the end of the 5th century B.C. After the fall of Athens he settled at the court of Archelaus, king of Macedonia, where he was the associate of Agathon, Melanippides, and Plato, the comic poet. The only work that can with certainty be attributed to him is the *Περσικά* or *Περσικά*, a history of the struggle of the Greeks against Persia. The treatment of contemporary events was a new departure in epic; he apologizes in the introductory verses (preserved in the scholiast on Aristotle, *Rhetoric*, iii.14). The *Perseis* was at first successful, but later critics reversed this favourable judgment. Aristotle (*Topica*, viii. I.) calls Choerilus's comparisons far-fetched and obscure, and the Alexandrians displaced him by Anti-

machus in the canon of epic poets.

G. Kinkel, *Epicorum Graecorum Frag.* i. (1877); for another view of his relations with Herodotus see Müder in *Klio* (1907), 29-44.

(3) An epic poet of Iasus in Caria, who lived in the 4th century B.C. He accompanied Alexander the Great on his campaigns as court-poet. He is well known from the passages in Horace (*Epistles*, ii. 1, 232; *Ars Poëtica*, 357), according to which he received a piece of gold for every good verse he wrote in honour of the deeds of his master.

See G. Kinkel, *Epicorum Graecorum Fragmenta*, i. (1877); A. F. Nöke, *De Choerili Samii Aetate Vita et Poësi aliisque Choerilis* (1817), where the above poets are carefully distinguished; and the articles in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1899).

CHOEROBOSCUS, GEORGIUS, also called CHARTOPHYLAX (c. A.D. 60), deacon and professor at the oecumenical school at Constantinople. A course of his lectures on grammar has come down to us in the shape of notes taken by his pupils. He drew from the best authorities—Apollonius Dyscolus, Herodian, Orion, Theodosius of Alexandria. These lectures were much used by Constantine Lascaris in his Greek grammar and by Urban of Belluno (end of 15th century). Other works: commentary on the canons of Theodosius on declension and conjugation, which is extant; a treatise on orthography, of which a fragment (on quantity) has been preserved; a tract on prosody; commentaries on Hephaestion and Dionysius Thrax; and grammatical notes on the Psalms.

BIBLIOGRAPHY.—See A. Hilgard, *Grammatici Graeci*, iv. (1889-94), containing the text of the commentary on Theodosius and a full account of the life and writings of Choeroboscus; L. Kohn in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1889); C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897); Reitzenstein, *Etymologica*, 190, n. 4.

CHOIR, the body of singers who perform the musical portion of the service in a church, or the place set apart for them (O.F. *cuer* from Lat. *chorus*, Fr. *choeur*). Any organized body of singers performing full part choral works or oratorios is also called a choir. The word was originally applied to all the clergy taking part in services of the church.

In English cathedrals the choir is composed of men (vicars-choral or lay clerks) and boys (choristers). They are divided into two sets, sitting on the north and south side of the chancel respectively, called *cantoris* and *decani* from being on the same side as the *cantor* (precentor) or the *decanus* (dean). Surplined choirs of women have occasionally been introduced, notably in the United States and the British colonies, but the practice has no warrant of traditional usage. (See **VESTMENTS**.) In England at the Reformation the choir services (Mattins, Evensong) replaced the Mass as the principal popular services, and, in general, only the choir vestments were retained in use. In the English cathedrals the members of the choir often retain privileges reminiscent of an earlier definite ecclesiastical status.

In architecture, (1) any part of a church intended for choir use, and (2), more commonly, the eastern end of a church, almost synonymous with chancel (*q.v.*). In developed churches of the middle ages, the choir is just to the west of the altar rail, usually between that and the crossing, although in some churches of England and Spain the space extends well into the nave (*q.v.*). In some modern churches members of the choir are placed in a western gallery; in Non-conformist churches they are frequently placed over and behind the pulpit. The choir stalls of Gothic churches such as Amiens, Exeter, Lincoln are works of great richness. In the illustration, Figure A. is from Gardner, *A Guide to English Gothic Architecture*, permission of the Cambridge University Press; C. and N. are by permission from Sir Banister Fletcher, *History of Architecture on the Comparative Method*, 8th ed. 1928 (Batsford); F. from Atkinson and Bagenal, *Theory and Elements of Architecture*, permission of Benn & Co.; L. from Greenwood, *Durham Cathedral*, permission of Andrews & Co.

CHOIRS, see **CHORAL SINGING** and **FESTIVALS, MUSICAL**.

CHOISEUL, CÉSAR, DUC DE (1598-1675), French marshal and diplomatist, known for the best part of his life as the marshal du Plessis-Praslin, came of the old French family of Choiseul, which arose in the valley of the Upper Marne in the

16th century. Entering the army he took part in the siege of La Rochelle, assisted to defend the island of Ré against the duke of Buckingham, and accompanied the French forces to Italy in 1629. In 1630 he was appointed ambassador at the court of the duke of Savoy, and was engaged in diplomatic and administrative work in Italy till 1635, when war was declared between France and Spain. Plessis-Praslin distinguished himself in the Italian campaign which followed, and after further service in Italy he was made a marshal of France (1645). During the first War of the Fronde he assisted Condé in the brief siege of Paris; and in the second war, remaining loyal to the queen-regent and the court party, he defeated Turenne and the allied Spaniards and rebels at Rethel (or Blanc-Champ) in 1650. He became minister of state in 1652, and in November 1665 was created duc de Choiseul. He was concerned in some of the negotiations between Louis and Charles II. of England which led to the Treaty of Dover, and died in Paris on Dec. 23, 1675.

CHOISEUL, ÉTIENNE FRANÇOIS, DUC DE (1719-1785), French statesman, was the eldest son of François Joseph de Choiseul, marquis de Stainville (1700-1770), and bore in early life the title of comte de Stainville. Born on June 28, 1719, he entered the army, and during the War of the Austrian Succession served in Bohemia in 1741 and in Italy, where he distinguished himself at the battle of Coni, in 1744. From 1745 until 1748 he was with the army in the Low Countries, being present at the sieges of Mons, Charleroi, and Maestricht. He acquired a large fortune by his marriage in 1750 with a daughter of the marquis de Châtel.

Choiseul gained the favour of Madame de Pompadour, and was given the appointment of ambassador to Rome in 1753, where he was entrusted with the negotiations concerning the disturbances called forth by the bull *Unigenitus*. In 1757 his patroness obtained his transfer to Vienna, where he was instructed to cement the new alliance between France and Austria. He then replaced Antoine Louis Rouillé (1689-1761) as minister for foreign affairs, and therefore had the direction of French foreign policy during the Seven Years' War. At this time he was made a peer of France and created duc de Choiseul. Although from 1761 until 1766 his cousin César, duc de Choiseul-Praslin, was minister for foreign affairs, yet Choiseul continued to control the policy of France until 1770, and during this period held most of the other important offices of state. As the author of the "Family Compact" he sought to retrieve by an alliance with the Bourbon house of Spain the disastrous results of the alliance with Austria, but his action came too late. He reformed both the army and navy, and although too late to prevent the loss of Canada and India, he developed French colonies in the Antilles and San Domingo, and added Corsica and Lorraine to the crown of France. His management of home affairs in general satisfied the *philosophes*. He allowed the publication of the *Encyclopédie* and procured the banishment of the Jesuits and the temporary abolition of the order by Pope Clement IV.

Choiseul's fall was caused by his action towards the Jesuits, and by his support of their opponent La Chalotais, and of the provincial parlements. After the death of Madame de Pompadour in 1764, his enemies, led by Madame du Barry and the chancellor Maupeou, were too strong for him, and in 1770 he was ordered to retire to his estate at Chanteloupe. Greatly to his disappointment Louis XVI. did not restore him to his former position, although the king recalled him to Paris in 1774, where he died on May 8, 1785.

CHOISY, FRANÇOIS TIMOLEON, ABBÉ DE (1644-1724), French author, was born in Paris on Aug. 16, 1644, and died in Paris on Oct. 2, 1724. His father was attached to the household of the duke of Orleans, and the lad became famous in court circles for his extravagance, his adoption of female dress and his numberless intrigues. He had been made an abbé in his childhood,

and poverty drove him to live on his benefice at Sainte-Seine in Burgundy, where he found a kindred spirit in Bussy-Rabutin. He visited Rome in the suite of the cardinal de Bouillon in 1676, and shortly afterwards a serious illness brought about a sudden conversion. In 1685 he accompanied the chevalier de Chaumont on a mission to Siam. He was ordained priest, and received various ecclesiastical preferments. He wrote voluminous historical works, but is remembered by his gossiping *Mémoires* (1737), which contain remarkably exact portraits of his contemporaries, although he has otherwise small pretensions to historical accuracy.

The *Mémoires* passed through many editions, and were edited in 1888 by M. de Lescure. Some admirable letters of Choisy are included in the correspondence of Bussy-Rabutin. Choisy is said to have burnt some of his indiscreet revelations, but left a considerable quantity of unpublished ms. Part of this material, giving an account of his adventures as a woman, was surreptitiously used in an anonymous *Histoire de madame la comtesse de Barres* (Antwerp, 1735), and again with much editing in the *Vie de M. l'abbé de Choisy* (Lausanne and Geneva, 1742), ascribed by Paul Lacroix to Lenglet Dufresnoy; the text was finally edited (1870) by Lacroix as *Aventures de l'abbé de Choisy*. See also Sainte-Beuve, *Causeries du lundi*, vol. iii.

CHOKE BORE, the bore of a gun narrowed at the muzzle to concentrate the shot.

CHOKE-DAMP, also known as "black-damp" and "stythe," is a mixture of carbon dioxide and nitrogen, pure choke-damp according to Dr. J. Haldane, containing about 13% of the former and 87% of the latter; but probably the relative proportions are variable. Choke-damp, which in this connection is more frequently known as "stythe," is found in old, abandoned, or worked portions of the mines—especially wet mines—where the ventilation is stagnant, and on the occasion of a fall in the atmospheric pressure emerges from the "wastes" ("goaves") and makes its appearance in the workings, and, being heavier than air, lies along the floor of the mine gradually ascending as it increases in volume.

Choke-damp is the result of the absorption of the oxygen in the air by the coal substance in the mine and the formation of carbon dioxide in the process; it is also produced by the decay of timber, the breathing of men and animals, the burning of lamps and candles, and the firing of explosives. Spontaneous combustion, or self-heating of coal, which is a characteristic of some coal mines, is merely the rapid absorption of oxygen by the coal, which produces carbon dioxide and carbon monoxide in the process.

Carbon monoxide is known to miners as "white-damp" but is present only in minute quantities in the mine. It is the result of incomplete combustion, may be caused by the exploding of gunpowder and other explosives, and is always present in the "after-damp" resulting from an explosion of fire-damp or of coal dust.

Whereas carbon dioxide, if present in sufficient quantity, extinguishes light and life mainly by suffocation, carbon monoxide, if present in the air to an extent greater than 1%, can be detected by a cap on the ordinary flame of a safety lamp. It is a virulent poison, its destructive effect being due to its action on the haemoglobin of the blood with which it chemically combines, robbing the body of its oxygen. But haemoglobin when saturated with carbon-monoxide cannot take up oxygen. An atmosphere containing as low as 0.2% of the dangerous gas will cause in time complete helplessness and loss of consciousness. An analysis of after-damp made by Dr. Bedson after the Usworth explosion (County Durham) in 1885 showed it to contain—

| | % |
|---|-------|
| Carbon dioxide (CO ₂)..... | 4.54 |
| Carbon monoxide (CO)..... | 2.48 |
| Methane (CH ₄ the chief constituent of fire-damp)..... | 8.68 |
| Oxygen..... | 7.23 |
| Nitrogen..... | 76.80 |

Analyses of after-damp by Mr. W. I. Orsman in 1892 showed it to be composed of—

| | % |
|----------------------|------|
| Oxygen..... | 3.9 |
| Nitrogen..... | 75.9 |
| Carbon dioxide..... | 12.1 |
| Carbon monoxide..... | 8.1 |

The bodies of persons killed by after-damp in which carbon monoxide was the fatal agent, present a pink and healthy look due

entirely to its coloration effect, and *rigor mortis* is not present. (R. R.)

CHOKING, the obstruction of a passage. In animals choking is an obstruction of the windpipe (*q.v.*) and may lead to suffocation (*q.v.*; see also LARYNGOTOMY; and TRACHEOTOMY). In electricity, a *choking coil* is designed so that it will pass alternating currents of low but not of high frequencies (see RADIO RECEIVER). In internal combustion engines (*q.v.*) a *choke-tube* is a constriction in a pipe, which increases the velocity of the fluid in its neighbourhood and thus reduces the pressure (see HYDROMECHANICS: *Bernoulli's Theorem*); this results in the liquid from the carburettor being sucked into the tube.

CHOLERA, the name formerly given to two distinct diseases, acute infective enteritis and Asiatic cholera but now restricted to Asiatic cholera alone. Although essentially different in causation and pathological relationships, these two diseases may in individual cases present many symptoms of resemblance.

Acute Infective Enteritis (synonyms, *cholera nostras*, *simple cholera*, *Cholera Europaea*, *British Cholera*, *Summer or Autumnal Cholera*) is the cholera of old medical writers. Its occurrence in an epidemic form was noticed in the 16th century. The chief symptoms in well-marked cases are vomiting and purging occurring either together or alternately. The seizure is usually sudden and violent. The diarrhoea is attended with severe griping abdominal pain, while cramps affecting the legs or arms greatly intensify the suffering. In unfavourable cases, particularly where the disorder is epidemic, death may result within 48 hours. Generally, however, the attack is arrested and recovery soon follows, although irritability of alimentary canal may remain for some time, rendering necessary the utmost care in diet. Attacks of this kind are frequent in summer and autumn in almost all countries. Occasionally the disorder prevails so extensively as to constitute an epidemic. The exciting cause conveyed by food or water is bacterial, *B. Enteritidis* (Gaertner) or an allied form being responsible for the majority of cases. The symptoms are those of toxic poisoning and collapse from loss of fluid. Hence the resemblance to Asiatic cholera.

Treatment.—Vomiting and diarrhoea are natural means whereby the harmful material is ejected, but if excessive must be controlled by opiates. Ice and effervescing drinks quench thirst and subdue sickness. Counter-irritation by mustard or turpentine over the abdomen is of use, as is friction with the hands where cramps are present. Food should be whey or albumin water. In young children reliance is placed on chalk and starch enemata; opium is dangerous.

Asiatic Cholera (synonyms, *Malignant Cholera*, *Indian Cholera*, *Epidemic Cholera*, *Algid Cholera*) is one of the most severe and fatal diseases. Three stages are usually described but often they cannot be distinguished. The first stage is characterized by mild and painless diarrhoea. This generally lasts for two or three days, and then may gradually subside or pass into the more severe phenomena characteristic of the second stage, or may itself prove fatal. This stage may pass unnoticed.

The second stage is that of collapse or the algide or asphyxial stage. Not infrequently this stage is the first to manifest itself. Often it starts suddenly in the night with diarrhoea of the most violent character, the matters discharged being whey-like ("rice-water" stools). They contain large quantities of disintegrated epithelium from the mucous membrane of the intestines. The discharge, which is at first unattended with pain, is soon succeeded by copious vomiting of matters similar to those passed from the bowels, accompanied by severe pain at the pit of the stomach, and intense thirst. The symptoms now advance with rapidity. Agonizing cramps of the legs, feet and abdominal muscles and signs of collapse supervene. The surface of the body becomes cold and blue or purple, the skin is dry and wrinkled, the features are pinched and the eyes deeply sunken, the pulse at the wrist is imperceptible, and the voice is reduced to a hoarse whisper. There is complete suppression of the urine. In this condition, death often occurs in less than one day, but in epidemics cases are frequently observed where the collapse is so sudden and complete as to prove fatal in one or two hours even without any great

amount of previous purging or vomiting. In most instances the mental faculties are comparatively unaffected, although towards the end there is in general more or less apathy. Reaction, however, may take place, and this constitutes the third stage. It

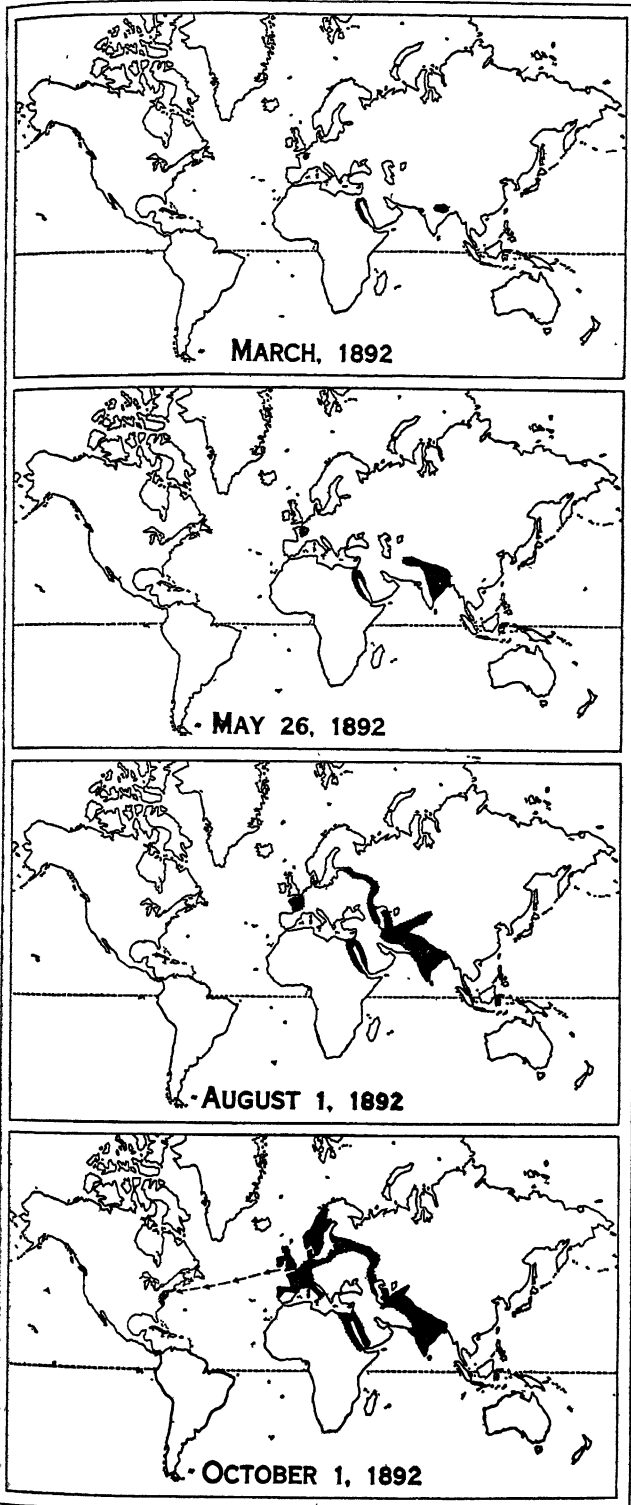

occur two or three weeks from the commencement of the illness.

The bodies of persons dying of cholera remain long warm, and the temperature may even rise after death. Peculiar muscular contractions have been observed after death, so that the position of the limbs may become altered. The soft tissues are dry and hard, and the muscles dark brown. The blood is tarry in character. The upper portion of the small intestines is generally found distended with the rice-water discharges, the mucous membrane is swollen, and there is extensive loss of its epithelium. The kidneys are usually in a state of acute congestion.

The cause of Asiatic cholera is a micro-organism identified by Koch in 1883 (*see* PARASITIC DISEASES). For some years it was called the "comma bacillus," but it was subsequently found to be a vibrio, not a bacillus. Apparently there are many strains of the vibrio which differ widely in toxicity and other characters. Probably this explains the great variations in epidemics.

Cholera is endemic in the East from Bombay to southern China, but its chief home is British India. It principally affects the alluvial soil near the mouths of the great rivers, particularly the delta of the Ganges. Lower Bengal is pre-eminently the standing focus and centre of diffusion. In some years it is quiescent, though never absent; in others it passes its natural boundaries and is carried east, north and west, it may be to Europe or America. The micro-organism is carried chiefly by infected persons moving from place to place; but soiled clothes, rags and other articles that have come into contact with persons suffering from the disease may be the means of conveyance to a distance. There is no reason to suppose that it is air-borne, or that atmospheric influences have anything to do with its spread, except in so far as meteorological conditions may be favourable to the growth and activity of the micro-organisms. Beyond all doubt, the great culture ground of the vibrio is the human body, and the discharges from it are the great source of contagion. They may infect the ground, the water, or the immediate surroundings of the patient, the poison finding entrance into the bodies of the healthy by means of food and drink which have become contaminated in various ways, *e.g.* by flies. Of all the means of local dissemination, contaminated water is the most important, because it affects the greatest numbers, particularly in places with a public water-supply. All severe outbreaks of an explosive character are due to this cause. It is also possible that the cholera poison multiplies rapidly in water under favourable conditions, and that a reservoir, for instance, may form a sort of forcing-bed. But it would be a mistake to regard cholera as purely a water-borne disease, even locally. It may infect the soil in localities which have a perfectly pure water-supply, but have defective drainage or no drainage at all, and then it will be found more difficult to get rid of, though less formidable in its effects, than when the water alone is the source of mischief. In all these respects it has a great affinity to enteric fever. With regard to locality, no situation is secure against attack if the disease is introduced and the sanitary conditions are bad; but, speaking generally, low-lying places on alluvial soil near rivers are more liable than those standing high or on a rocky foundation. Of meteorological conditions it can only be said with certainty that a high temperature favours the development of cholera, though a low one does not prevent it. In temperate climates the summer months, and particularly August and September, are the season of its greatest activity.

Cholera spreads westwards from India by two routes—(1) by sea to the shores of the Red sea, Egypt and the Mediterranean; and (2) by land to northern India and Afghanistan, thence to Persia and central Asia, and so to Russia. In the great invasions of Europe during the 19th century it sometimes followed one route and sometimes the other. An Indian epidemic of 1817 reached Europe by way of Persia and Russia in 1830 and extended to America. Another of 1841 followed the same track and reached Europe and America in 1847. A third took place in the East in 1850 and entered Europe in 1853; this epidemic was specially severe throughout North and South America. Other epidemics visiting Europe occurred in 1866, 1869-74, 1883-87; these travelled by way of the Mediterranean. The epidemic of 1892-95 reverted to the overland route and travelled with unprecedented

MERCATOR PROJECTIONS OF THE WORLD SHOWING THE SPREAD OF CHOLERA IN THE EPIDEMIC OF 1892

consists in arrest of the alarming symptoms characterizing the second stage, and gradual but evident improvement in the patient's condition. The urine may remain suppressed for some time, and on returning is often albuminous. Even in this stage, however, the danger is not past, for fatal relapses sometimes occur or reaction may be so imperfect that death from exhaustion may

rapidity. Within less than five months it travelled from the North-West provinces of India to St. Petersburg (Leningrad) and probably to Hamburg, and thence in a few days to England and the United States. During the period of 1910-25 cholera continued to be widely prevalent in India, and the recorded mortality exceeded 500,000 in both 1918 and 1919, when the disease was also epidemic in China, but, with the exception of moderate prevalence in eastern and southern Europe, including Italy in 1911, there has been little spread to Europe. Bengal maintains its unenviable reputation as the home of cholera.

Prevention.—The great invasion of 1892-95 was fruitful in lessons for the prevention of cholera. It proved that the one real and sufficient protection lies in a standing condition of good sanitation backed by an efficient and vigilant sanitary administration. The experience of Great Britain where the deaths per 10,000 living were less than 0.05 was a remarkable piece of evidence, but that of Berlin was perhaps even more striking, for Berlin lay in the centre of four fires, in direct and frequent communication with Hamburg, Russia, France and Austria, and without the advantage of a sea frontier. Cholera was repeatedly brought into Berlin, but never obtained a footing, and its successful repression was accomplished without any irksome interference with traffic or the ordinary business of life. The general success of Great Britain and Germany in keeping cholera in check by ordinary sanitary means completed the conversion of all enlightened nations to the policy laid down so far back as 1865 by Sir John Simon, and advocated by Great Britain at a series of international congresses—the policy of abandoning quarantine, which Great Britain did in 1873, and trusting to sanitary measures with medical inspection of persons arriving from infected places. This principle was formally adopted at the international conference held at Dresden in 1893, at which a convention was signed by the delegates of Germany, Austria, Belgium, France, Great Britain, Italy, Russia, Switzerland, Luxembourg, Montenegro and the Netherlands. Under this instrument the practice is broadly as follows, though the procedure varies a good deal in different countries: Ships arriving from infected ports are inspected, and if healthy are not detained, but bilge-water and drinking-water are evacuated, and persons landing may be placed under medical supervision without detention; infected ships are detained only for purposes of disinfection; persons suffering from cholera are removed to hospital; other persons landing from an infected ship are placed under medical observation, which may mean detention for five days from the last case; or, as in Great Britain, supervision in their own homes, for which purpose they give their names and places of destination before landing. All goods are freed from restriction, except rags and articles believed to be contaminated by cholera matters. By land, passengers from infected places are similarly inspected at the frontiers and their luggage “disinfected,” only those found suffering from cholera can be detained. Each nation is pledged to notify the others of the existence within its own borders of a “focus” of cholera. The precise interpretation of the term is left to each government, and is treated in a rather elastic fashion by some, but it is generally understood to imply the occurrence of non-imported cases in such a manner as to point to the local presence of infection. The question of guarding Europe generally from the danger of diffusion by pilgrims through the Red sea was settled at another conference held in Paris in 1894. The provisions agreed on included the inspection of pilgrims at ports of departure, detention of infected or suspected persons, and supervision of pilgrim ships and of pilgrims proceeding overland to Mecca.

The substitution of the procedure above described for the old measures of quarantine and other still more drastic interferences with traffic presupposes the existence of a sanitary service and fairly good sanitary conditions if cholera is to be effectually prevented. No doubt if sanitation were perfect in any place or country, cholera, along with many other diseases, might there be ignored, but sanitation is not perfect anywhere, and therefore it requires to be supplemented by a system of notification with prompt segregation of the sick and destruction of infective material. Of general sanitary conditions the most important

is unquestionably the water-supply. The classical example is Hamburg. The water-supply is obtained from the Elbe, which became infected by some means not ascertained. The drainage from the town also runs into the river, and the movement of the tide was sufficient to carry the sewage matter up above the water-intake. The water itself, which is no cleaner than that of the Thames at London Bridge, underwent no purification whatever before distribution. It passed through a couple of ponds, supposed to act as settling tanks, but owing to the growth of the town and increased demand for water it was pumped through too rapidly to permit of any subsidence. On the other hand, at Altona, which is continuous with Hamburg, the water was filtered through sand. In all other respects the conditions were identical, yet in Altona only 328 persons died, against 8,605 in Hamburg. In some streets one side lies in Hamburg, the other in Altona, and cholera stopped at the dividing line, the Hamburg side being full of cases and the Altona side untouched. In the following year, when Hamburg had the new filtered supply, it enjoyed equal immunity, save for a short period when raw Elbe water accidentally entered the mains.

But water, though the most important condition, is not the only one affecting the incidence of cholera. The case of Grimsby furnished a striking lesson to the contrary. Here the disease obtained a decided hold, in spite of a pure water-supply, through the fouling of the soil by cesspits and defective drainage. At Havre also its prevalence was due to a similar cause. Further, it was conclusively proved at Grimsby that cholera can be spread by sewage-fed shell-fish. Several of the local outbreaks in England were traced to the ingestion of oysters obtained from the Grimsby beds. In short, it may be said that all insanitary conditions favour the prevalence of cholera in some degree. Preventive inoculation with an attenuated virus was introduced by W. M. W. Haffkine, and has been extensively used in India, with considerable appearance of success so far as the statistical evidence goes.

Treatment.—Happily, during the decades 1905-25, important progress has been made in the treatment of cholera, which has robbed the disease of half its terrors when hospital accommodation is available. Leonard Rogers of the Indian medical service, as the result of his researches on the blood changes in the disease and of the action of permanganates in destroying the toxins formed by the cholera vibrios in the intestines, has established a system of treatment which has reduced the mortality in the Calcutta hospital cases to about one-third of its former rate. The great loss of fluid and salts from the blood, and the reduction of the alkalinity of that fluid are combated by the intravenous injection in severe cases of three to five or more pints at a time of the following solutions: (1) sodium bicarbonate grains 160 and sodium chloride grains 90 in a pint of sterile water, and (2) sodium chloride grains 120 and calcium chloride (as a cardiac tonic) grains four to a pint; one pint of the former alkaline solution and the remaining two to four pints of the second hypertonic saline being given whenever collapse occurs, or the blood is found to be concentrated by the specific gravity test; 20 to 30 pints being sometimes administered successfully in the course of a few days in very bad cases, while the alkaline solution is also given in half-pint quantities in enemata every two to four hours until the renal excretion is fully re-established. In addition two permanganate pills of two grains each are given orally every 15 to 30 minutes during the stage of acute evacuations to destroy the toxins in the bowel. Kaolin, or fine China clay, has the power of loosely combining with cholera toxins and preventing their absorption from the intestines, so equal quantities of kaolin and water should be given to drink *ad libitum*. Pituitrin injections are of value to maintain the blood pressure and increase the renal secretion in the later stages, and injections of atropine in doses 1/100 grain twice a day are also of value as first suggested by Lauder Brunton. As the cramps and other symptoms are immediately relieved by the saline injections, opium is unnecessary and should never be given in any stage of cholera, as it strongly predisposes to fatal suppression of urine.

By these methods the mortality in over 1,000 severe cases in the Calcutta cholera ward over a number of years past has been reduced from 60% to 20% and equally good results were obtained

in China in 1919. In the Bombay and Central Provinces the administration of large quantities of permanganate pills in outbreaks in villages remote from hospitals has reduced the death-rate one-half to one-third of that in untreated cases in the same epidemics, although the severest types require intravenous salines in addition if life is to be saved. The great paucity of skilled medical men in Indian villages alone prevents greater saving of life by these methods, and prevention, especially by good water supplies and greater sanitary control of cholera-spreading places of pilgrimage within the endemic areas of the disease in Lower Bengal and south-east Madras, together with the compulsory inoculation against cholera of all pilgrims before being allowed to return to their homes from cholera areas, should be generally adopted without further loss of time if this very serious cause of mortality in India is to be reduced, as it well might be, and Europe saved from further pandemics of cholera.

CHOLET, a town of western France, capital of an *arrondissement* in the department of Maine-et-Loire, 33 m. E.S.E. of Nantes. Pop. (1926) 17,910. Cholet stands on high ground on the right bank of the Maine, which is crossed by a 15th century bridge. Megalithic monuments are numerous in the neighbourhood. The town owes the rise of its prosperity to the settlement of weavers there by Edouard Colbert, count of Maulévrier, a brother of the great Colbert. It suffered severely in the War of La Vendée of 1793. A public garden occupies the site of the old castle. The town possesses a sub-prefecture, a tribunal of first instance, a chamber of commerce and a board of trade-arbitrators. There are granite quarries in the vicinity. The chief industries are the manufacture of linen and of preserved foods. Cholet is an important centre for the sale of fat cattle, sheep and pigs, for which Paris is the chief market.

CHOLON ("great market"), a town of French Indo-China, the largest commercial centre of Cochin China, 3½ m. S.W. of Saigon, with which it is united by railway, tramways, roads and canal. Cholon was founded by Chinese immigrants about 1780, and is situated on the Chinese *arroyo* at the junction of the Lo-Gom and a canal. Its waterways are frequented by innumerable boats and lined in some places with native dwellings built on piles, in others by quays and houses built by the French, who have also carried out drainage schemes, installed electric lighting in the main streets and erected factories, schools, hospitals and administrative buildings. Its population is almost entirely Asiatic. In 1880 the population was 45,000; in 1927 it numbered about 200,000. Of these about 50,000 were Chinese, divided into congregations according to their place of origin. During the rice season the town is visited by a large floating population. Cholon is administered by a municipal council, composed of French, Annamese and Chinese traders. An administrator of native affairs, nominated by the governor, fills the office of mayor. The rice trade, almost monopolized by the Chinese, is the leading industry. Tanning, dyeing, copper-founding, glass, brick and pottery manufacture, stone working, timber-sawing and junk building are other industries.

CHOLONAN, a linguistic stock of South American Indians, so called from the Cholones, its most important tribe. The Cholonan Indians live in eastern Peru, between the eastern crest of the Andes and the upper Huallaga river, from the Monzon in the south to the Mayo in the north. Missions were established among them in the 17th century, so that they have now largely lost their original culture. They are sedentary agriculturists, and still retain the use of the blow-gun, widely distributed among the neighbouring tribes to the north and east. They live in cane-walled, thatched-roof houses, but, unlike their neighbours to the north and east, do not use the hammock for sleeping. They appear to have had elaborate puberty ceremonies for the young men.

See E. Poeppig, *Reise in Chile, Peru und auf dem Amazonenstrom*, etc. (Leipzig, 1835).

CHOLULA, an ancient town of Mexico, in the State and on the plateau of Puebla, eight miles by rail W. by N. of the city of that name, and situated about 6,912 ft. higher than sea-level. Pop. (1921) 6,282. The Inter-oceanic railway passes through Cholula, but the city's commercial and industrial standing is overshadowed by that of its larger and more modern neighbour. At the time of the Spanish conquest, Cholula—then known as Chololan—was a large and important town, consecrated to the worship of the god Quetzalcoatl, who had here one of the most imposing temples in Anahuac, built on the summit of a truncated pyramid, the largest of its kind in the world. This pyramid, constructed of sun-dried bricks and earth, 177 ft. high, and covering an area of nearly 45 ac., is the most conspicuous object in the town and was built probably as an imposing site for a temple. Nothing definite is known of its age and history, as the fanatical zeal of Cortés and his companions destroyed whatever historical data the temple may have contained. Cholula was visited by Cortés in 1519 during his eventful march inland to Montezuma's capital, Tenochtitlán, when he treacherously massacred its inhabitants and pillaged the city, pretending to distrust the hospitable inhabitants. Cortés estimated that the town then had 20,000 habitations, and its suburbs as many more, but this was undoubtedly a deliberate exaggeration. The Cholulans were of Nahuatl origin and were semi-independent, yielding only a nominal allegiance to Montezuma. They were a trading people, holding fairs, and exchanging their manufactures of textiles and pottery for other produce. The pyramid is believed to have been built by a people occupying this region before the Cholulans.

CHOPIN, FRÉDÉRIC FRANÇOIS (1810-1849), Polish musical composer and pianist, was born at Zelazowa-Wola, near Warsaw, on Feb. 22, 1810 (*not* Mar. 1, 1809). His father, of French origin, born at Nancy in 1770, had married a Polish lady, Justine Krzyzanowska. Frédéric was their third child. His first musical education he received from Adalbert Ziwny, a Czech musician, who is said to have been a passionate admirer of J. S. Bach. He also received a fair general education at the recently-founded Lyceum of Warsaw, where his father was professor of French. His musical genius opened to Chopin the best circles of Polish society, at that time unrivalled in Europe for its ease of intercourse, the beauty and grace of its women, and its liberal appreciation of artistic gifts. These early impressions were of lasting influence on Chopin's development. While at school he received thorough instruction in the theory of his art from Joseph Elsner, a learned musician and director of the conservatoire at Warsaw. When in 1829 he left his native town for Vienna, where his *début* as a pianist took place, he was in all respects a perfectly formed and developed artist. There is in his compositions little of that gradual progress which, for instance, in Beethoven, necessitates a classification of his works according to different periods. Chopin's individuality and his style were distinctly pronounced in that set of variations on "La ci darem" which excited the wondering enthusiasm of Robert Schumann. In 1831 he left Vienna with the intention of visiting London; but on his way to England he reached Paris and settled there for the rest of his life. Here again he soon became the favourite and musical hero of society. His connection with Mme. Dudevant, better known by her literary pseudonym of George Sand (*q.v.*), is an important feature of Chopin's life. When in 1839 his health began to fail, George Sand went with him to Majorca, and it was mainly owing to her tender care that the composer recovered his health for a time. Chopin declared that the destruction of his relations with Mme. Dudevant in 1847 broke up his life. The association of these two artists has provoked a whole literature on the nature of their relations, of which the novelist's *Un Hiver à Majorque* was the beginning. The last ten years of Chopin's life were a continual struggle with the pulmonary disease to which he succumbed in Paris Oct. 17, 1849. The year before his death he visited England, where he was received with enthusiasm by his numerous admirers. Chopin died in the arms of his sister, who hastened from Poland to his death-bed. He was buried in the cemetery of Père Lachaise.

In looking through the list of Chopin's compositions, teeming

with mazurkas, waltzes, polonaises, and other forms of national dance music, one might hardly suppose that here one of the most melancholy natures revealed itself. This seeming paradox is explained by the type of Chopin's nationality, of which it has justly been said that its very dances are sadness intensified. Yet notwithstanding its strongly pronounced national characteristics, Chopin's music is always expressive of his individual feelings and sufferings in the highest possible degree. He is indeed the lyrical composer *par excellence*, and the intensity of his expression finds its equal in literature only in the songs of Heinrich Heine, to whom he has been so often likened. Such high-strung passion cannot be prolonged, and hence it was in works of small compass, such as the nocturne and the étude, that Chopin found the happiest expression of his genius. In compositions of larger scope he was out of his element, and even the beauty of his melodies and harmonies cannot wholly banish the impression of incongruity. Fortunately, he himself had an unerring sense of his own limitations, though there could be no greater mistake than to suppose that because he wrote in the smaller forms he was not, even so, one of the greatest of masters. Chopin's piano-playing was as exquisite as his music, and many accounts left by his contemporaries have testified to the irresistible fascination which he exercised by performances described as the last word in delicacy, subtlety and refinement.

It is well to sift the posthumous works from those published under Chopin's direction, for the last three mazurkas are the only things he did not keep back as misrepresenting him. On these principles his mature works are summed up in the 42 mazurkas (Opp. 6, 7, 17, 24, 30, 33, 41, 50, 56, 59, 63, and the beautiful contribution to the collection *Notre temps*); seven polonaises (Opp. 26, 40, 53, 61); 24 preludes (in all the major and minor keys), Op. 28, and the single larger prelude, Op. 45; 27 études (12 in Op. 10, 12 in Op. 25, and 3 written for the *Méthode des méthodes*); 18 nocturnes (Opp. 9, 15, 27, 32, 37, 48, 55, 62); 4 ballades, in forms of Chopin's own invention (Opp. 23, 38, 47, 52); 4 scherzos (Opp. 20, 31, 39, 54); 8 waltzes (Opp. 18, 34, 42, 64); and several pieces of various description, notably the great fantasia, Op. 49, and the impromptus, Opp. 29, 36, 51. The posthumous works number 35 pieces, besides a small volume of songs a few of which are of great interest.

The editions of Chopin's works by his pupil Mikuli and by Klindworth are full of valuable elucidation as to methods of performance, but unfortunately they do not distinguish the commentary from the text. The critical edition published by Breitkopf and Härtel, with all its mistakes, is absolutely necessary for students who wish to know what Chopin wished to put into the hands of players of independent judgment.

The Chopin literature is very extensive. The standard biography is the English work of Prof. F. Niecks (1888), while other leading works are those by Liszt, Karasowski and Huneker. See also W. H. Hadow, *Studies in Modern Music*, Henry Bidou, *Chopin* (1927) and G. Ashton Jonson's useful *Handbook to Chopin's Works*.

CHOPSTICKS, the "pidgin-English" name for the pair of small tapering sticks used by the Chinese in eating. (Chinese *kwai-tse* "the quick ones," "chop"-quick.) They are made of

wood, bone, or ivory, somewhat longer and thinner than a lead-pencil. Held between the thumb and fingers, they are used to take up portions of food, cut up into small pieces. Many rules of etiquette govern the proper conduct of the chopsticks; laying them across the bowl is a sign that the guest wishes to leave the table; they are not used during a time of mourning, when food is eaten with the fingers; and various methods of handling them form a secret code of signalling.

CHORALE, a term in music used by English writers to indicate the hymn-tunes composed or adopted for use in church by the German reformers (Lat. *Choralis*). German writers, however, apply the terms "Choral" and "Chorale-geesang," as Luther himself would have applied them, to any solemn melody used in the church. It is thus the equivalent of *canto fermo*; and the German rhymed versions of the biblical and other ancient canticles, such as the Magnificat and the Te Deum, are set to curious corruptions of the corresponding Gregorian tunes, which adaptations the composers of classical German music called chorales with no more scruple than they applied the name to tunes of secular origin, German or foreign. The peculiarity of German chorale-music, however, is that its use, and consequently much of its invention, not only arose in connection with the Reformation, by which the liturgy of the church became "understood of the people," but also that it belongs to a musical epoch in which symmetry of melody and rhythm was beginning to assume artistic importance. The growing sense of form shown by some of Luther's own tunes (e.g., *Vom Himmel hoch, da komm' ich her*) soon advanced, especially in the tunes of Crüger, beyond any that was shown by folk-music; and it provided a massive bulwark against the chaos that was threatening to swamp music on all sides at the beginning of the 17th century.

By Bach's time all the polyphonic instrumental and vocal art-forms of the 18th century were mature; and though he loved to derive the design as well as the details of a large movement from the shape of the chorale tune on which it was based, he became quite independent of any aid from symmetry in the tune as raw material. The chorus of his cantata "Jesus nun sei gepreiset" is one of the most perfectly designed and quite the longest of movements ever based upon a chorale-tune treated phrase by phrase. Yet the tune is one of the most intractable in the world, though its most unpromising portion is the basis of the most impressive feature in Bach's design (the slow middle section in triple time.)

In recent times the great development of interest in folk-music, and the discovery of the unique importance of Bach's work, have combined to tempt writers on music to over-estimate the distinctness of the art-forms based upon the German chorale. There is really nothing in these art-forms which is not continuous with the universal practice of writing counterpoint on a *canto fermo*. Thus Handel in his Italian and English works wrote no entire chorale movements, yet what is the passage in the "Hallelujah" chorus from "the kingdom of this world" to the end, but a treatment of the second part of the chorale "Wachet auf"? Again, to return to the 16th century, what are the hymns of Palestrina but figured chorales? In what way, except in the lack of symmetry in the Gregorian phrasing, do they differ from the contemporary setting by Orlando di Lasso, also a Roman Catholic, of the German chorale "Vater unser im Himmelreich"? In later times the use of German chorales, as in Mendelssohn's oratorios and organ-sonatas, has had rather the aspect of a revival than of a development; though the technique and spirit of Brahms's posthumous organ chorale-preludes is thoroughly modern and vital.

One of the most important, and practically the earliest collection of "Chorales" is that made by Luther and Johann Walther (1496-1570), the "Enchiridion," published in 1524. Next in importance we may place the Genevan Psalter (1st ed., Strasbourg, 1542, final edition 1562), which is now conclusively proved to be the work of Bourgeois. From this Sternhold and Hopkins borrowed extensively (1562). The psalter of C. Goudimel (Paris, 1565) is another among many prominent collections showing the steps towards congregational singing, i.e., the restriction to "note-against-note" counterpoint (sc. plain harmony), and, in 12 cases,

the assigning of the melody to the treble instead of to the tenor. The first hymn-book in which this latter step was acted on throughout is Osiander's "Geistliche Lieder . . . also gesetzt, das ein christliche Gemein durchaus mitsingen kann" (1586). But many of the finest and most famous tunes are of much later origin than any such collections. Several (e.g., "Ich freue mich in dir") cannot be traced before Bach, and were very probably composed by him. (D. F. T.)

CHORAL SINGING. In Great Britain choral singing, from 1913 to 1928, falls into three periods—the splendid activity which was checked by the World War, the struggles during that dark period, and the efforts since 1919 to find means of meeting the new situation. In the first period there was extraordinary vitality and much new impetus.

Some Notable Figures.—The old tradition of solid, square-toed choralism had been shaken to the roots by the personality of Dr. (now Sir) Henry Coward, the Sheffield chorus master. He had turned the big, heavy, unwieldy body of the provincial choral society into a living, sensitive, functioning organism, and his exploits had created a sensational interest in this form of art. Some of his disciples, no doubt, carried his ideas too far and lost sight of the end in exploiting the means. There were other notable workers in the field, with different aims, each contributing to the general good. Harry Evans, by his work in Wales and Liverpool, his keen personality and penetrating insight, made a great impression on the choral world. He was particularly successful in modern works for large choirs, exploiting vivid colouring. His comparatively early death in 1914 was a severe loss.

Two other choirs, also under men of outstanding personality, were beginning to attract attention. Both were breaking away from the lines traditionally followed by the average British choral society. In 1904 Charles Kennedy Scott, an able and versatile musician, founded in London the Oriana Madrigal Society, a small body originally intended to arouse interest in the English madrigal school. It eventually widened its scope and devoted much attention to modern British unaccompanied choral works, and in the period in question it was becoming firmly established in public notice. The choice of programmes struck out new lines and gave fresh ideas to choral conductors all over the world.

In Glasgow an amateur musician, Hugh S. Robertson, was attracting attention by the skilled singing of his Orpheus Choir, a body of about 120 singers, concentrating mostly on Scottish song arrangements and unaccompanied works on a small scale. Dr. E. C. Bairstow, organist of York Minster since 1913, was proving himself one of the most able choral conductors in the land, and a church musician who made the services at the Minster among the finest of the world.

The period being described was also remarkable for experiments in choral composition. The new technique acquired by large choral societies and the enormous strides made by choirs in touch with the competition festival movement opened up new possibilities to composers. The most daring experimentalist was Granville Bantock, who, in 1912-14, wrote *Atalanta in Calydon* and *The Vanity of Vanities*. Entitled choral symphonies, they are divided into four movements on the lines of the traditional orchestral form, and are written for unaccompanied voices. The voices are disposed in 20 and 12 parts respectively, not with a view to polyphonic writing, but to obtain contrasts of colour on the lines of strings, wind and brass of the orchestra. Many highly original effects are obtained, and severe problems set for choir and trainer.

Recent Developments.—On the conclusion of the World War the task of reconstruction proved even greater than had been anticipated. Traditions had been broken and the formerly constant supply of tenors and basses was not and has not been recaptured. Subscribers who had supported institutions for many years as a duty did not resume their help. The war, too, had accelerated a change of taste which had gradually been coming about. Standard societies had always been able to rely upon the popular oratorios of Handel and Mendelssohn to crowd houses and fill coffers. *The Messiah* had paid many and many a deficit. But, generally speaking, this was no longer the case. Moreover, costs of halls, or-

chestra, printing and advertising, were all higher, and in addition there was the devastating entertainment tax. Consequently few societies could meet their expenses.

On the other side of the account, however, there was a new awakening of competition festivals, which, firmly established before the war, have attained an extraordinary vitality since. One great value of this movement is that it affords a *raison d'être* for the existence of every kind of society, except the larger bodies. Rural festivals bring into existence choirs in the smallest of villages, and the larger festivals stimulate the virtuosity of the leading bodies. Choirs connected with churches and chapels, women's institutes, guilds, boy scouts, all sorts of male, female and mixed organizations, are encouraged, improved and given a new outlook. In this way the problem of finding an audience for a concert and making ends meet may be avoided.

There has been a remarkable development of male voice choirs, mostly of working men, often connected with factories or works of various kinds, and these have, to a certain extent, thinned the male ranks of mixed choirs. A keen sense of sportsmanship and comradeship results in much more intensive work than is customary with mixed choirs. "Trade" bodies were willing to submit to 60 or 70 rehearsals of a single part song. A much higher standard of music is now obtained through the influence of these festivals. The singing of madrigals has received an immense impetus. Choral arrangements of folk songs and compositions by the best of our modern composers are being brought within the ken of many thousands of people. For some festivals choirs prepare choruses from an important work which is finally given by combined forces. In this way tiny rural villages know their Bach cantatas, and are even intimate with the B minor Mass and other large-scale compositions.

Another striking development of importance has been the growth of "works" choirs, some of which are very fine bodies. The Glasgow police and tramways choirs and the L.N.E.R. Musical Society are examples. One interesting fact is being disclosed by this activity. It was thought that the best choral singing was to be found only in Yorkshire, and that other parts of the country could not hope to rival that county. But the opinion of most adjudicators is that first-rate work can be produced anywhere. Without doubt the most robust voices come from this northern county, and in other parts of the country the current quality is less adapted to powerful and brilliant results, but a good conductor can produce superlatively good results from material existing in any district in the British Isles. Adjudicators of the widest experience have found astonishing results in places which were supposed to be unmusical. The general consensus of opinion among critics at the Leeds festival of 1925 was that although vocally the choir there was perhaps the finest in the world, technically it was inferior to many bodies in other parts of the country. This change of centre foreshadows a new era in choral singing.

Some Notable Choirs.—In London the Oriana Choir continues to do good work, forming a model for madrigal singing, and producing the latest works of modern British composers. In 1919 the Philharmonic Choir was formed in order that a large choral body might be affiliated with the Philharmonic Society. Kennedy Scott was appointed conductor, and he had proved as brilliant with a large choir as with a small one. Among the important works produced, in addition to classics, have been Bax's motets and the choral works of Delius. In particular, the performance of the *Mass of Life* in April 1925, reached a remarkable standard. London possesses, for the first time in its history, both a large and a small choir which can give performances unexcelled anywhere else in the kingdom. A junior philharmonic choir, composed of young women, is now in existence. Besides giving concerts of its own, it forms a source from which experienced singers can be drafted into the main body.

In Scotland.—The Glasgow Orpheus Choir has reached a state of popularity unprecedented in the history of choral singing, and maintains the level of its superlatively polished performances. It attracts crowded audiences in Glasgow, gives concerts all over Scotland, and makes annual raids into England. It has done

much to stimulate choral singing; its policy has been to afford opportunities for the training of conductors, and to give advice and assistance on the question of formation of new choirs. It is probably the first time that any choir has undertaken missionary work on such a large scale. A most successful tour was made in Canada and the United States of America, in the summer of 1926, and the reputation of British choral singing was brilliantly enhanced. In Manchester the Hallé Choir (chorus master, Mr. Dawber) has within late years won fresh honours at the concerts conducted by Sir Hamilton Harty.

Changes of Taste.—A significant feature in recent years has been the greatly increased interest in Bach. At the beginning of the century Bach was considered suitable for only the finest choirs, and especially cultured audiences. His cantatas were almost unknown in Britain. Now large and small societies produce his larger works frequently, and his church cantatas are being regularly performed. Reference may be made in this connection to an experiment, the founding of the Newcastle-upon-Tyne Bach Choir in 1915 to perform the works of the master, not with the wrong proportions of an orchestra of 50 and a choir of 300, but with forces approximating to those used in his day. The choir, after a period of experiment, was fixed at 40, ten to a line. The orchestra varies according to the work concerned; in some cases it is practically equal to the choir in numbers. Besides all the large works of Bach and the motets, about 80 of his cantatas have been given. A three days' Bach festival was given in London in Feb. 1921. British composers are also included in the scheme of work, over 60 having been represented. It gave in Newcastle cathedral in 1924 the first known complete performance of Byrd's recently discovered *Great Service*, and the Carnegie United Kingdom Trust sent the choir to give three performances of it in St. Margaret's, Westminster, London, in November of the same year. Several choirs have been formed on its lines, in Doncaster, Stockton, Leicester, Liverpool, and are helping to spread a knowledge of Bach unrivalled in any other country outside Germany if, indeed, that country is not now outdistanced in this direction by Great Britain. A Bach Cantata Club began operations in London in Feb. 1926, under the direction of C. K. Scott.

The Newcastle-upon-Tyne Bach Choir was invited to sing at the festival of the International Society for Contemporary Music, in Frankfurt-on-Main in July 1927, and afterwards made a short tour of German university towns, singing unaccompanied British music ranging from Byrd to Holst.

Advance in Technique.—It is impossible in a short article even to mention all the manifestations of choral singing throughout Great Britain. As a result of the competition festival movement, new conductors of merit are appearing everywhere. Works which, a few years ago, were looked upon as extremely difficult, for instance, Elgar's *Gerontius*, are now sung in many small towns. The work in question will receive 50 to 60 performances every winter. To take a single example, an isolated town like Kendal, with a population of 14,000, can produce such works as Holst's *Cloud Messenger* and Vaughan Williams' *Sea Symphony*.

At the same time the improved standard of choral singing has inspired a series of fine works by British composers. Vaughan Williams' unaccompanied *Mass*, and his oratorio, *Sancta Civitas*, Holst's *Hymn of Jesus* and first choral symphony, and a remarkable group of unaccompanied motets by Arnold Bax, are a tribute like to the technical efficiency of choral bodies and to the vitality and high level of the great tradition of native compositions for choirs.

Community singing has been another development of the movement and was inaugurated in 1915 on the lines of successful gatherings in Australia. Meetings were organized at which folk, national, and simple classical songs were sung in unison, and easy sounds were rehearsed, the music being taught by pattern, so that no technical knowledge was demanded from the singers. This caught on in a remarkable way, and the movement promises to become a permanent feature of national life, closely allied with the folk dance revival. Notable leaders are Gibson Young (who was one of the prime movers in Australia), Geoffrey Shaw, Sir

Richard Terry, and Sir Hugh Allen.

In the Dominions.—British choirs overseas bid fair to follow the good example of the Mother Country. Dr. Fricker, late of Leeds, is doing splendid work in Toronto. The Winnipeg Male Voice Choir, under Hugh Ross (since conductor of the Schola Cantorum in New York) impressed visiting adjudicators greatly. British adjudicators returning from recent competitive festival tours, report that choral activity may outdistance the Mother Country in a short time, and speak enthusiastically of a remarkable standard of performance. Possibly by virtue of its climate, Australia produces splendid women's voices, which rather outweigh the men's. South Africa is producing some astonishing results with native races, especially in schools, where early maturity enables fully fledged four-part singing to be cultivated. There is much choral activity in the main centres of that continent. (W. G. W.)

THE UNITED STATES

The early growth of choral music in the United States, as elsewhere, was associated with the Church. It was the Puritans of New England rather than the Dutch colonists of New York who were mainly responsible for the earliest developments, and this although the Pilgrim fathers brought to America a hatred of musical culture that is without parallel in history. Over a century of controversy was required, indeed, before the Church reluctantly accepted organized singing in "the new and ruleable way," which simply meant singing from the printed page rather than constantly repeating the traditional tunes from memory. Even late in the 18th century some localities still sang in "the usual way," which often consisted of the congregation's singing parts of two or three different tunes to one stanza of a hymn, or even singing different tunes at the same time. These melodies were sung so slowly that it was often necessary to take breath twice on one and the same tone or word-syllable.

In the face of such a handicap, it is surprising that early choral singing developed as rapidly as it did. But the acceptance of organized singing in the Church brought with it the advent of the singing school, with its psalm-tune teacher, and thereafter the choral society was a natural development. An early, but it must be admitted not too well authenticated, report describes a performance of the *Messiah* with organ accompaniment in the New York Trinity church as long ago as Jan. 9, 1770, less than 28 years after the original production of the work.

Early Organizations.—Probably the first stable organization of amateur singers in America was the Stoughton Musical Society, founded in Stoughton, Mass., by the first American composer, William Billings, in 1786. This antedates by five years the famous Berlin *Singakademie*. A rapid growth of similar choral societies followed, so that by 1812 the regularly established amateur choruses in America already outnumbered those of Germany, although the latter were doubtless vastly superior in quality. Of more lasting influence than the Stoughton Society was the Handel and Haydn Society, founded in Boston in 1815. This, while it lasted, became to America what the *Singakademie* of Berlin was to Continental Europe—the model for all similar organizations throughout its native country. It may be added that this society, whose present conductor is Thompson Stone, actually negotiated with Beethoven for a new choral work.

Henceforward, choral societies appeared in rapid succession. The short-lived Handel and Haydn Society of New York gave way to the New York Choral Society and the New York Sacred Music Society, both established in 1823, though the former only lasted a year. In 1844 the Musical Institute of New York was founded, but by 1850 it was saved only by an amalgamation of the three New York choral groups, the Vocal Society, the Sacred Music Society and the American Musical Institute, all combining to form the New York Harmonic Society. As a result of a controversy the short-lived Mendelssohn Society was formed in 1863, but nothing of a permanent nature was established until 1873, when Dr. Leopold Damrosch organized the New York Oratorio Society, which remains to-day as probably the foremost choral organization in the United States.

New York Oratorio Society.—Starting with a group numbering from 15 to 20, and giving its first concert with only 60 voices, Dr. Damrosch lived to direct such a festival as that of 1881 when he conducted a chorus of 1,200 and an orchestra of 250. At his death the work was continued by his son Walter and later, for a short period, by Frank Damrosch. Louis Koemenich, a German conductor, did much for the development of the Oratorio Society. Since 1921 the society has been under the leadership of Albert Stoessel, who, in its annual Christmas production of the *Messiah*, and performances of other compositions of the great classical masters, as well as of modern works, has continued the traditions of the organization. In 1927 the society gave the first complete performance in New York of Bach's *B Minor Mass*.

The Oratorio Society shares with the more recent Schola Cantorum of New York, founded by Kurt Schindler in 1909 (Hugh Ross, conductor), and the still more recent Society of the Friends of Music, founded in 1913 (Artur Bodanzky, conductor), the responsibility of maintaining the highest ideals of choral singing in New York.

It was due largely to the singing schools of New England that choral culture found its way to other sections of the country. In the west, Cincinnati became a choral centre, developing around the German population who were responsible for the first American *Sängerfest* in 1849, just four years after such reunions had been introduced in Würzburg, Germany. Theodore Thomas was responsible for the first of the famous Cincinnati festivals, in 1873. With one exception they have taken place biennially since that time, and lead the western contingent in choral enterprise. The conductor in 1927 was Frank van der Stucken.

Of eastern choral festivals, two are of outstanding importance. The annual Worcester (Mass.) music festival was established in 1858 under the name of Musical Convention. In 1873 it became the Worcester County Musical Festival. The annual Bach festival at Bethlehem, Pa., is devoted to the works of the great master, and was responsible for the first complete American performance of the *B Minor Mass*.

To-day the choral societies in the United States are almost innumerable; Philadelphia alone boasts over 60, and the number of such bodies throughout the whole country is being added to every year.

CHORAL SYMPHONY, a symphony including choral movements or numbers. Beethoven's ninth symphony, with vocal finale for four solo singers and chorus, is the most famous of all such works. Another is Mendelssohn's *Hymn of Praise*. Among more recent composers Mahler wrote several choral symphonies.

CHORAZIN and **BETHSAIDA**. Towns in the neighbourhood of Capernaum (Mth. xi. 21; Lk. x. 13). Since the 18th century the former has been identified with a ruined site *Khīrbet Kerāzeh* about 2 m. N. of *Tell Hūm* (Capernaum). Amongst the ruins are the remains of a synagogue built of black basalt. Scholars are divided as to whether one Bethsaida is to be sought or two. Those who favour one generally locate it east of the Jordan at *Et-Tell* or *El-'Ardj* (either site answering the description of Bethsaida-Julias of Josephus, *Antiq.* xviii. 2. 1) or at *Mas 'adiyeh*. Those who would look for a separate "Bethsaida of Galilee" (John xii. 21) have advocated variously *Tell Hūm*, *'Ain et-Tābighah*, *Khīrbet (Khān) Mīnyeh* or *'Ain et-Tīneh*. Now that *Tell Hūm* has been identified with Capernaum, the identification of *Khīrbet Mīnyeh* with Bethsaida is being urged.

CHOREA: see ST. VITUS'S DANCE.

CHORIAMBIC VERSE or **CHORIAMBICS**, lyric verse based on the choriambus, a group of four syllables, — — — — (i.e., choree or trochee + iamb). It is especially characteristic of Aeolic verse, as that of Alcaeus, Sappho, and their Latin imitator Horace, but is not confined to it. Regularly, one or more choriambi are preceded, or followed, or both, by other groups of syllables, as

hōc deā ue[r]ē Sybārim | cūr properās | amāndō (Greater Sapphic).

īnteger ūi | tae sceleris | quē pūrūs (Sapphic hendecasyllable).
sic frā|trēs Helenae | lucidā sīlderā (Lesser Asclepiad).
tū ne | quāesieris | scire nefās | quēm mihi quēm | tibi
(Greater Asclepiad).

These and other varieties are arranged into various stanzas. These are essentially metres meant for song, not recitation, and are used to express emotion, serious or trivial. See GLYCONIC, SAPPHIC METRE.

Modern music often contains choriambi, but the few attempts at these in modern verse are mere *tours de force* as Gilbert Murray's:—

"an old | eagle, a blind | eagle who waits | hungry and cold | and still."

CHORICIUS, of Gaza, Greek sophist and rhetorician, flourished in the time of Anastasius I. (A.D. 491–518). He was the pupil of Procopius of Gaza, who must be distinguished from Procopius of Caesarea, the historian. His declamations, often accompanied by commentaries, include, besides panegyrics, funeral orations, and stock themes, *Epithalamioi*, or wedding speeches. Choricus was also the author of so-called *Ekphraseis*, descriptions of works of art after the manner of Philostratus. His moral maxims were largely drawn upon by Macarius Chrysocephalus, metropolitan of Philadelphia (middle of the 14th century), in his *Rodonia* (rose-garden). A special feature of Choricus' style is the avoidance of hiatus, peculiar to what is called the school of Gaza.

Editions by J. F. Boissonade (1846, supplemented by C. Graux in *Revue de philologie*, 1877), and R. Förster (1882–94); see also C. Kirsten, "Quaestiones Choricianae" in *Breslauer philologische Abhandlungen*, vii. (1894); G. Pietsch, "De Chorio Patrocli declamationis auctore" in same publication (1910), and article by W. Schmid in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1899). On the Gaza school see K. Seitz, *Die Schule von Gaza* (Heidelberg, 1892).

CHORIN, AARON (1766–1844), Hungarian rabbi and pioneer of religious reform, born at Weisskirchen, Moravia, on Aug. 3, 1766, educated at Prague, and became rabbi at Arad in 1789. His *Emek ha Shaweh* (Vale of the Plain) of 1803 was declared heretical by the orthodox party, but he continued to favour such reforms as modification of the traditional laws, vernacular prayers, and the use of the organ. Chorin was also interested in the promotion of schools, seminaries, and professions among the Jews. He died on July 26, 1844.

See L. Low: *Gesammelte Schriften* vol. ii. (Szegedin, 1889).

CHORIZONTES ("separators"), the name given to the Alexandrian critics who denied the single authorship of the *Iliad* and *Odyssey*, and held that the latter poem was the work of a later poet. The most important of them were the grammarians Xenon and Hellanicus; Aristarchus was their chief opponent (see HOMER).

CHORLEY, a municipal borough in North Lancashire, England, 22 m. N.W. from Manchester, on the L.M.S.R. and the Leeds and Liverpool Canal. Pop. (1931) 30,795. Area, 3,614 acres. The town is situated on the "fall-line" between a westward projection of the Pennines and the North Lancashire Plain. The church of St. Lawrence is of Perpendicular and earlier date, largely restored, and contains fine woodwork. Textiles, railway-wagon making and metal-working are the chief industries. The district contains a number of coal-mines and stone-quarries. There is a large reservoir of the Liverpool Corporation Water Works with a capacity for 48,300,000 gallons. Close to the town is the beautiful Elizabethan mansion of Astley Hall. The town is in the Chorley Parliamentary Division of Lancashire.

CHORLU, a town of European Turkey, in the vilayet of Adrianople; on the left bank of the Chorlu, a small left-hand tributary of the Ergene, 20 m. N.E. of Rodosto. Pop. (1905) was about 12,000, of whom one-half were Greeks, one-third Turks, and the remainder Armenians and Jews. The Greeks and Armenians have now left. Chorlu has a station on the Constantinople-Adrianople branch of the Oriental railways. It manufactures woollen cloth (*shayak*) and native carpets, and exports cereals, oil-cloth, carpets, cattle, poultry, fresh meat, game, fruits,

vine, alcohol, hides and bones.

CHOROGRAPHY. (1) A description or delineation on a map of a district or tract of country (from the Gr. *χώρα*, a tract of country, and *γράφειν*, to write). The word is common in old geographical treatises, but is now superseded by the wider use of "topography" (*q.v.*). (2) A system of notation to indicate the steps and movements in dancing.

CHOROTEGA, a group of linguistically related Indian tribes located on the west coasts of Honduras (Choluteca), Nicaragua (Mangue), and Costa Rica (Orotiña). Other groups are found in southern Mexico. All have lost their tribal identity, although the Mangue dialect is still in existence. Archaeological evidence assigns to the Chorotega an important place in the aboriginal culture history of Central America, for early phases of the Chorotega underlie the most ancient remains of the Maya.

See S. K. Lothrop, "Pottery of Costa Rica and Nicaragua," *Contributions from the Museum of the American Indian, Heye Foundation*, vol. viii., 1926, p. 20-100.

CHOROTES, a tribe of South American Indians belonging to the Matacan (*q.v.*) linguistic stock. The Chorotes live in southern Bolivia on the eastern side of the upper Pilcomayo river. They are a tall, long-headed folk, with a simple semi-nomadic type of culture. The dress of both sexes is a short kilt of skins or coarse woollen cloth. To-day, at least, the Chorotes practise some agriculture. They live in small, rudely thatched huts. They have no canoes. The bow is the main weapon. Simple pottery and netted bags are made. Village chiefs are hereditary and have considerable power. A peculiar feature of social life is that the women select their husbands.

See E. Nordenskiöld, *Indianerleben; El Gran Chaco* (Leipzig, 1913).

CHÓRUM, the chief town of the vilayet of the same name in Asia Minor, altitude 2,300 ft., on the edge of a plain, almost equidistant from Amasia and Yozgat. Pop. (1927) 60,752. The ancient *Euchaïta*, 15 m. E., was attacked by the Huns A.D. 508, and became a bishopric at an early period. It contained the tomb of the revered St. Theodore, who slew a dragon in the vicinity and became one of the great warrior saints of the Greek Church. (See J. G. C. Anderson, *Studia Pontica*, pp. 6 ff.)

CHORUS (Gr. *χορός*), properly a dance, and especially the sacred dance, accompanied by song, of ancient Greece at the festivals of the gods. The word *χορός* seems originally to have referred to a dance in an enclosure, and is therefore usually connected with the root appearing in Gr. *χόρος*, hedge, enclosure, Lat. *hortus*, garden, and in the Eng. "yard," "garden" and "garth." In the chorus sung in honour of Dionysus the ancient Greek drama had its birth. From that of the winter festival, consisting of the *κῶμος* or band of revellers, chanting the "phallic songs," with ribald dialogue between the leader and his band, sprang "comedy," while from the dithyrambic chorus of the spring festival came "tragedy." (For the history of the chorus in Greek drama see *DRAMA: Greek Drama*.)

The chorus as a factor in drama survived only in the various imitations or revivals of the ancient Greek theatre in other languages. A chorus is found in Milton's *Samson Agonistes*. The Elizabethan dramatists applied the name to a single character employed for the recitation of prologues or epilogues. Apart from the uses of the term in drama, the word "chorus" has been employed chiefly in music. It is used of any organized body of singers, in opera, oratorio, cantata, etc., and, in the form "choir," of the trained body of singers of the musical portions of a religious service in a cathedral or church. As applied to musical compositions, a "chorus" is a composition written in parts, each to be sung by groups of voices in a large body of singers. The word is also used of that part of a song repeated at the close of each verse, in which the audience or a body of singers may join with the soloist.

In the early middle ages the name *chorus* was given to a primitive bagpipe without a drone. Giraldus Cambrensis in his *Topographia Hiberniae* mentions it as one of the three instruments of Wales and Scotland, though there is some reason to believe that he may have been confusing it with the crot or crwth, an entirely different instrument. It is further recorded that King James I. of Scotland was renowned for his skill as a performer on various

musical instruments, one of which was the chorus.

CHOSE, a term used in law in different senses. *Chose local* is a thing annexed to a place, as a mill. A *chose transitory* is that which is movable, and can be carried from place to place. But the use of the word "chose" in these senses is practically obsolete, and it is now used only in the phrases *chose in action* and *chose in possession*. A "chose in action," in its more limited meaning, denotes the right to sue for a debt or damages, whether arising out of a contract or a tort. Less accurately, the money itself which could be recovered is frequently termed a chose in action, as is also sometimes the document evidencing a title to a chose in action, such as a bond or a policy of insurance, though strictly it is only the right to recover the money which can be so termed. Choses in action were either *legal* or *equitable*. Where the chose could be recovered by an action at law, as a debt (whether arising from contract or tort), it was termed a legal chose in action; where the chose was recoverable only by a suit in equity, as a legacy or money held upon a trust it was termed an equitable chose in action.

The courts of Common law did not originally (except in the case of negotiable instruments) recognize the assignment of choses in action. Any attempt to assign a chose in action was invalid, and if the debtor paid the assignee, he could be compelled to pay the debt over again to the assignor. The only way in which a debt could be transferred was by a new contract of a tripartite nature in which the debtor was released by the assignor, and consented, in consideration of such release, to become liable to the assignee. This was a novation, not an assignment. But courts of equity at an early date gave effect to an assignment of a chose in action for valuable consideration, treating the assignee as an agent of the assignor with an irrevocable authority to collect and keep the proceeds. By the end of the eighteenth century the law courts adopted a similar doctrine permitting the assignee to sue in the assignor's name. *Winch v. Keeley*, 1 T.R. 619. In America statutes known as real party in interest statutes are common permitting the assignee to sue in his own name. In England under the Judicature Act of 1783 as amended by the Law of Property Act, 1925, permits the assignee to sue in his own name without joining the assignor, provided (a) the assignment was absolute and not by way of charge only; (b) the assignment was in writing; and (c) notice in writing was given to the debtor or party to be charged.

See Williston, *Contracts*, c. 14.

A chose in possession is opposed to a chose in action, and is a thing in actual physical possession. A chose in possession is freely transferable by delivery.

CHOSEN: see *KOREA*.

CHOSROES (*chōs-rōōs'*), in middle and modern Persian *Khosrau* ("with a good name"), a common name, borne by a king of the Iranian legend (Kai Khosrau); by a Parthian king, commonly called by the Greeks Osroes (*q.v.*); and by the following two Sassanid kings.

1. **CHOSROES I.**, "the Blessed" (*Anushirvan*), A.D. 531-579, successor of Kavadh I., and the most famous of the Sassanid kings. At the beginning of his reign he concluded an "eternal" peace with the emperor Justinian, who wanted to be free for the conquest of Africa and Sicily. But successes against the Vandals and Goths caused Chosroes to renew the war in 540. He invaded Syria and took Antioch, and during the next years fought successfully in Lazica or Lazistan (the ancient Colchis, *q.v.*), on the Black sea, and in Mesopotamia. In 545 an armistice was concluded and in 562 a peace for 50 years, in which the Persians left Lazistan to the Romans, and the Romans paid subsidies to Persia. Meanwhile in the east the Hephthalites had been attacked by the Turks, who now appear for the first time in history. Chosroes united with them and conquered Bactria, while he left the country north of the Oxus to the Turks. He also assisted the dynasts of Yemen to expel the Ethiopians and Yemen became dependent on Persia. In 571 a new war with Rome broke out about Armenia, in which Chosroes conquered the fortress Dara on the Euphrates, invaded Syria and Cappadocia, and returned with large booty. During the negotiations with the emperor

Tiberius, Chosroes died in 579, and was succeeded by his son Hormizd IV.

Although Chosroes had extirpated the heretical Persian sect of the Mazdakites (*see* KAVADH) he was a tolerant adherent of Zoroastrian orthodoxy. He introduced a system of taxation, based upon a survey of landed possessions begun by his father.

2. CHOSROES II., "the Victorious" (*Parvez*), 590-628, son of Hormizd IV. and grandson of Chosroes I., was raised to the throne by the magnates who had rebelled against his father in 590. At the same time the general Bahram Chobin proclaimed himself king. The war with the Romans, begun in 571, had not yet ended. Chosroes fled to Syria, and persuaded the emperor Maurice (*q.v.*) to send help. Many acknowledged Chosroes, and in 591 he was brought back to Ctesiphon and Bahram Chobin beaten. Peace with Rome was then made, Maurice merely restoring the former frontier and abolishing the subsidies which had formerly been paid to the Persians. When in 602 Maurice was murdered by Phocas, Chosroes began war with Rome to avenge his death. His armies plundered Syria and Asia Minor, and in 608 advanced to Chalcedon. In 613 and 614 Damascus and Jerusalem were taken by the general Shahrbaraz, and the Holy Cross seized. Soon after, Egypt fell. The Romans could offer little resistance, as they were torn by internal dissensions, and pressed by the Avars and Slavs. At last, in 622, the emperor Heraclius (successor of Phocas in 610) was able to take the field. In 624 he advanced into northern Media, where he destroyed the great fire-temple of Gandzak (Gazaca); in 626 he fought in Lazistan, while Shahrbaraz advanced to Chalcedon and tried in vain to conquer Constantinople. In 627 Heraclius defeated the Persian army at Nineveh and advanced towards Ctesiphon. Chosroes fled, and as his despotism and indolence had roused opposition, his eldest son, Kavadh II., whom he had imprisoned, was set free and proclaimed king. Four days afterwards, Chosroes was murdered (Feb. 628). Meanwhile, Heraclius returned in triumph to Constantinople; in 629 the Cross was given back to him and Egypt evacuated, while the Persian empire, from the apparent greatness which it had reached ten years earlier, sank into hopeless anarchy.

See PERSIA: *Ancient History*, and the references there given. For the Roman war *see* authorities quoted under MAURICE and HERACLIVS.

CHOTA NAGPUR, a division of British India in Bihar and Orissa, consisting of five British districts, viz., Hazaribagh, Ranchi, Palamau, Manbhum and Singhbhum. Chota Nagpur consists of a hilly, forest-clad plateau, inhabited mostly by aboriginal races, between the basins of the Son, the Ganges and the Mahanadi. The total area is 27,065 sq. miles. The population in 1921 was 5,653,028. The plateau is an offshoot of the great Vindhyan range, and its mean elevation is upwards of 2,000ft. above the sea-level. It is not an open table-land, but broken up by numerous ranges and hills enclosing ravines and valleys. A large area is still under forest. The principal agricultural products are rice, Indian corn, pulses, oil-seeds and potatoes. A small quantity of tea is grown in Ranchi district. The principal jungle products are timber, lac, tussur silk and *mahuá* flowers, which are used as food and also distilled into a strong country liquor. Chota Nagpur contains the Jharia, Giridih, Bokaro, Karanpura, Ramgarh and Daltonganj coal-fields. The output in 1925 was nearly 14 million tons or 70% of the total output of India. It has other valuable mineral resources. Mica is mined in Hazaribagh and iron ore in Singhbhum, where the output is already nearly half a million tons; there is a belt of copper ore in the latter district, where also manganese ore, gold, chromite and apatite occur; and important deposits of bauxite have been found in Ranchi and Palamau.

The indigenous inhabitants consist of non-Aryan tribes, the principal of whom are the Hos, Oraons, Santals, Mundas and Bhumij. Except in Palamau these tribes were never subdued by the Mohammedans, who contented themselves with occasional expeditions and an irregular tribute of diamonds. Until the country passed under British rule, moreover, there was very little communication between Chota Nagpur and the plains of India, with the result that the tribes have preserved to a large extent

their languages, customs and primitive religions.

CHOUANS, the name given to the bands of peasants, mainly smugglers and dealers in contraband salt, who rose in revolt in the west of France, in 1793, and joined the royalists of la Vendée (*see* FRANCE: *History*). The Breton word *chouan* means "screech-owl," and is supposed to have been originally applied as a nickname to Jean Cottureau (1767-94), the leader of the revolt, and afterwards extended to his followers. In any case, it was appropriate; for they were night-birds and used the hoot of an owl as a signal. The motive for revolt was less devotion to the monarchy than resentment at interference of the new Republican Government with their old habits; the ruin of their contraband trade by the abolition of the *Gabelle* (*q.v.*); the attacks by the Convention on the priesthood, and, above all, the enforcement of conscription. Their methods of warfare were barbarous and were met by barbarous reprisals. A vivid picture of these wild people and the wild country in which they operated is given by Balzac in his novel *Les Chouans*.

Daudet, *La Police et les Chouans dans le Consulat et l'Empire, 1800-15* (1895). Also the works of Ch. L. Chessin mentioned under VENDÉE.

CHOUTEAU, AUGUSTE (1739-1829), American pioneer, was born in New Orleans, La., in 1739. With his younger brother Pierre (1749-1849), he was the founder of the city of St. Louis, Mo. In August, 1763, they joined the expedition of Pierre Liguette Laclède who had received a commission from the director-general of Louisiana to establish the fur trade in the country west of the Mississippi. In this party Auguste was given command of the boat, and in October, 1763, they reached the settlement of Sainte Genevieve. In the winter they ascended to a point some 60 miles upstream and chose a site on the western bank for their chief trading station, which they named St. Louis. On Feb. 15, 1764, a party under the direction of Auguste Chouteau began active trading operations. The two brothers remained permanently in the new settlement and built up a large and profitable fur trade with the Indians of the North and West. Auguste died in St. Louis on Feb. 24, 1829. His son Pierre Chouteau (1789-1869), developed an immense business in furs, becoming an associate of John Jacob Astor (*q.v.*).

CHOUGH (*Pyrrhocorax graculus*), a bird of the crow family. It inhabits mountains and rocky coasts in Europe and North Africa. The combined effects of persecution by man and competition with the jackdaw (*q.v.*) have reduced its numbers greatly and it is now rare. Recognized by its black plumage and bright red legs and red, curved beak, the Cornish chough is more slenderly built than the crows. The Alpine chough (*P. graculus*), with a yellow bill, is gregarious.

CHRESTIEN, FLORENT (1541-1596), French satirist and Latin poet, the son of Guillaume Chrestien, a French writer on physiology, was born at Orleans on Jan. 26, 1541. A pupil of Henri Estienne, the Hellenist, at an early age he was appointed tutor to Henry of Navarre, afterwards Henry IV., who made him his librarian. Brought up as a Calvinist, he became a convert to Catholicism. He was one of the authors of the *Satyre Ménippée*, the famous pasquinade in the interest of his old pupil, Henry IV., and his works include a Latin version of *Hero and Leander* and French versions of Buchanan's *Jephthé* and Oppian's *De Venatione*. He died at Vendôme on Oct. 26, 1596.

CHRÉTIEN DE TROYES, a native of Champagne, and one of the famous French mediaeval poets. We possess very few details as to his life, and opinion differs as to the exact date to be assigned to his poems. We know that he wrote *Le Chevalier de la Charrette* at the command of Marie, countess of Champagne (the daughter of Louis VII. and Eleanor of Aquitaine, married to the count of Champagne in 1164), and *Le Conte du Graal*, or *Perceval* for Philip, count of Flanders, guardian of the young king, Philip Augustus from 1180 to 1182. As Chrétien refers to the

story as the best tale told *au cort roial* it was probably composed during the regency. It was left unfinished, and later continued by three writers, Wauchier de Denain, Gerbert de Montreuil and Manessier. The second of these says definitely that Chrétien died before he could complete his poem. The extant works in their chronological order are, *Érec*, *Cligès*, *Le Chevalier de la Charrette* (*Lancelot*), *Le Chevalier au Lion* (*Yvain*) and *Le Conte du Graal* (*Perceval*) all dealing with Arthurian legend. Besides these he himself mentions a *Tristan*, and certain translations from Ovid's *Ars amatoria*, and *Metamorphoses*. A portion of this last was found by Gaston Paris, included in the translation of Ovid by Chrétien Legouais; of the *Tristan* no trace has yet been discovered. There is also a poem, *Guillaume d'Angleterre*, the authorship of which is a matter of debate. Prof. Foerster claimed it as by Chrétien, and included it in his edition of the poems, but Gaston Paris never accepted it.

Chrétien's poems enjoyed widespread favour, and of the three most popular (*Érec*, *Yvain* and *Perceval*) there exist old Norse translations, while the first two were admirably rendered into German by Hartmann von Aue. There is an English translation of the *Yvain*, *Yvain and Gawain*, and there are Welsh versions of all three stories, though their exact relation to the French is still a matter of debate. Chrétien's style is easy and graceful, he is analytic but not dramatic, in depth of thought and power of characterization he is decidedly inferior to Wolfram von Eschenbach, and as a poet he is probably to be ranked below Thomas, the author of *Tristan*, and the translator of Thomas, Gottfried von Strassburg. Much that has been claimed as characteristic of his work has been shown by M. Willmote to be merely reproductions of literary conceits employed by his predecessors. In the words of so competent a judge as M. J. Bédier he appears to have been "not so much a creative artist as a clever compiler" and this probably represents what will be the final verdict on his work.

BIBLIOGRAPHY.—Chrétien's poems, except the *Perceval*, have been critically edited by Prof. Foerster. There is so far no edition of the *Perceval* save that printed from the Mons ms. by M. Potvin (6 vols., 1866–71, out of print and difficult to procure). Prof. Baist published a private and limited edition of ms. 794 of the *Bibl. Nationale*. Dr. Mary Williams is publishing an edition of the Gerbert continuation in the *Classiques Français du Moyen Âge*. For general criticism of Chrétien's work, see Willmote, *L'Évolution du roman français aux environs de 1150* (1903); also J. L. Weston, *Legend of Sir Lancelot and Legend of Sir Perceval* and for an appreciation, M. Borodine, *La Femme et l'amour au XII^e siècle, d'après les poèmes de Chrétien de Troyes* (1909).

CHRISM, a mixture of olive oil and balm, used for anointing in the Roman Catholic church in baptism, confirmation and ordination, and in the consecrating and blessing of churches, altars, chalices, baptismal water, etc. (through Med. Lat. *chrisma*, from Gr. *χρίσμα*, an unguent). The consecration of the chrism is performed by a bishop during the High Mass on Maundy Thursday. In the Orthodox Church the chrism contains, besides olive oil, many precious spices and perfumes, and is known as "muron" or "myron." The "Chrisom," originally a head-cloth to prevent the chrism from being rubbed off a newly-baptized child's forehead, came to mean the white baptismal robe, which was used as the child's shroud if it died within the month, but was otherwise given to the church by the mother at her churching. Children dying within the month were called "chrisom-children" or "chrisoms," as in Mrs. Quickly's description of Falstaff's death (Shakespeare, *Henry V.*, ii. 3).

CHRIST, the Anointed One (Gr. *Χριστός*), equivalent to the Hebrew Messiah: the title given in the New Testament to Jesus of Nazareth. (See **JESUS CHRIST**, **MESSIAH**, **CHRISTIANITY**.)

CHRIST, WILHELM VON (1831–1906), German classical scholar, was born at Geisenheim, on Feb. 8, 1831, and died on Feb. 8, 1906, at Munich, where he had been professor from 1860 to 1902. His most important works are his *Geschichte der griechischen Literatur* (5th ed., 1908 f.), a history of Greek literature down to the time of Justinian, one of the best works on the subject; *Metrik der Griechen und Römer* (1879); editions of Pindar (1887); of the *Poëtica* (1878) and *Metaphysica* (1895) of Aristotle; *Iliad* (1884).

See O. Crusius, *Gedächtnisrede* (Munich, 1907).

CHRISTADELPHIANS, sometimes also called Thomasites, a community founded in 1848 by John Thomas (1805–1871), who, after studying medicine in London, migrated to Brooklyn, N.Y., U.S.A. (*Χριστοῦ ἄδελφοι*, "brothers of Christ"). There he at first joined the "Campbellites," but afterwards struck out independently, preaching largely upon the application of Hebrew prophecy and of the Book of Revelation to current and future events. Both in America and in Great Britain he gathered a number of adherents, and formed a community which has extended to several English-speaking countries. They believe that they alone hold the true interpretation of Scripture. Their theology is strongly millenarian, centring in the hope of a world-wide theocracy with its seat at Jerusalem. No statistics of the community are published.

See R. Roberts, *Dr. Thomas, his Life and Work* (1884); and F. J. Powicke, art. "Christadelphians" in Hastings' *Encyclopaedia of Religion and Ethics*. The community publishes a monthly magazine, *The Christadelphian*, in Birmingham.

CHRISTCHURCH, municipal borough, Hampshire, England, at the confluence of the rivers Avon and Stour, $1\frac{1}{2}$ m. from the sea, and $25\frac{1}{2}$ m. S.W. of Southampton on the S.R. Pop. (1931) 9,183. The neighbourhood was of great importance in late pre-historic times. Much of the late bronze and early iron age intercourse of Britain with the continent seems to have focused on Hengistbury Head and Christchurch. The town is mentioned in Saxon documents under the name of Tweotneam or Tweonaetean, which long survived in the form Christchurch Twineham. In 901 it was seized by Aethelwald, but was recaptured by Edward the Elder. In Domesday, under the name of Thuinam, it appears as a royal manor, comprising a mill and part of the king's forest. Henry I. granted Christchurch to Richard de Redvers, who erected the castle. Only fragments remain, but the ruined Norman House apparently dates from the later part of the 12th century. The famous Augustinian priory church of the Holy Trinity is cruciform in plan, lacking a central tower but having a Perpendicular tower at the west end. The nave and transepts are principally Norman, and very fine; the choir is Perpendicular. Early English additions appear in the nave, clerestory and elsewhere, and the rood-screen is of ornate Decorated workmanship. The priory attained to such fame that its name of Christchurch finally replaced the older name of Twineham. It was dissolved in 1539. The first charter was granted by Baldwin earl of Exeter in the 12th century; the 2nd Earl Baldwin granted to the burgesses the tolls of the fair at St. Faith and common of pasture in certain meads. These charters were confirmed by Edward II., Henry VII. and Elizabeth. The Holy Trinity fair is mentioned in 1226. Christchurch was not incorporated till 1670. The chief occupations are gardening, wood and metal working; some salmon fishing is carried on. There is a small harbour. From 1572 the borough was represented in the House of Commons by two members until the Reform Act of 1832 reduced the number to one. It is at present included in the New Forest and Christchurch Division of Hants. The area of the municipal borough is 2,352 acres.

CHRISTCHURCH, a city near the east coast of South Island, New Zealand, to the north of Banks Peninsula, in Selwyn county, the capital of the provincial district of Canterbury and the seat of a bishop. Pop. (1927) 122,000, including suburbs. It stands on the great Canterbury plain; a background is supplied by the distant mountains to the west, and by the nearer hills to the south. The small river Avon winds through the city. The wide streets cross one another for the most part at right angles, and there is a predominance of stone and brick as building materials. There are also well-planted parks, avenues and private gardens. Christchurch is mainly dependent on the rich agricultural district which surrounds it, the plain being mainly devoted to cereals and grazing. Wool is extensively worked, and meat is frozen for export. Railways connect with Culverden to the north and with Dunedin and the south coast, with many branches through the agricultural districts; also with Lyttelton, the port of Christchurch, 8 m. south-east. There are tramways in the city, and to

New Brighton, a seaside suburb, and other residential quarters.

The principal public buildings are the government buildings and the museum, with its fine collection of remains of the extinct bird, moa. The cathedral is the best in New Zealand, built from designs of Sir G. Gilbert Scott in Early English style, with a tower and spire 240 ft. high. Among educational foundations are Canterbury College (for classics, science, engineering, etc.), Christ's College (mainly theological) and grammar school, and a school of art. There is a Roman Catholic pro-cathedral attached to a convent of the Sacred Heart. A large extent of open ground comprises Hagley Park, recreation grounds, the Government Domain and the grounds of the Acclimatization Society, with fishponds and a small zoological garden. The foundation of Christchurch is connected with the so-called "Canterbury Pilgrims," who settled in this district in 1850. Lyttelton was the original settlement, but Christchurch came into existence in 1851, and is thus the latest of the settlements of the colony. It became a municipality in 1862. In 1903 several populous suburban boroughs were amalgamated with the city.

CHRISTENSEN, JENS CHRISTIAN (1856—), Danish politician, was born in North Jutland. The son of a peasant farmer, he was an elementary school teacher from 1877 to 1901. In 1890 he entered Parliament and eventually became leader of the Liberal party. In 1901 he was Minister of Education in the first Liberal government, and from 1905 to 1908 was Prime Minister. In 1909 he was Minister of Defence and in this capacity carried through the Army bill. From 1912 to 1913 he was Speaker of the *Folketing* (Lower House), from 1916 to 1918 minister without portfolio, and Minister of Worship from 1920 to 1922. He retired from politics in 1924. He has published a book, *Fra min Barndom og Ungdom* (1925).

CHRISTIAN II. (1481–1559), king of Denmark, Norway and Sweden, son of John (Hans) and Christina of Saxony, was born at Nyborg Castle on July 1, 1481, and succeeded his father as king of Denmark and Norway in 1513. As viceroy of Norway (1502–12) he had already displayed singular capacity. Patriotism, courage, statesmanship—these qualities were indisputably his; but unfortunately they were vitiated by obstinacy, suspicion and a sulky craftiness, beneath which simmered a very volcano of revengeful cruelty. Christian's succession to the throne was confirmed at the *Herredag* or assembly of notables from the three northern kingdoms, which met at Copenhagen in 1513. A decision as to the Swedish succession was postponed, as the Swedish delegates refused to accept Christian as king. On June 11, 1514, he was crowned king of Denmark and Norway at Copenhagen, and on the same day he married, by proxy, Isabella, sister of the future emperor Charles V. The wedding was celebrated on Aug. 12, 1515. But he would not give up his liaison with Dyveke, a Dutch girl of bourgeois origin, and on the death of the unfortunate girl in 1517, under suspicious circumstances, Christian revenged himself by executing the magnate Torben Oxe, who was supposed to have been Dyveke's murderer, despite the strenuous opposition of Oxe's fellow peers; henceforth the king lost no opportunity of depressing the nobility and raising plebeians to power. His chief counsellor was Dyveke's mother Sigbrit, a born administrator and a commercial genius of the first order. Christian first appointed her controller of the Sound tolls, and ultimately committed to her the whole charge of the finances. A *bourgeoise* herself, Sigbrit soon became the soul of a middle-class inner council, which competed with the *Rigsraad* itself. The patricians naturally resented their supersession and nearly every unpopular measure was attributed to the influence of "the foul-mouthed Dutch sorceress who hath bewitched the king."

Meanwhile Christian was preparing for the inevitable war with Sweden, where the Patriotic Party, headed by the freely elected governor Sten Sture the younger, stood face to face with the philo-Danish Party under Archbishop Gustavus Trolle. Christian, who had already taken measures to isolate Sweden politically, hastened to the relief of the archbishop, who was beleaguered in his fortress of Stäke, but was defeated by Sture and his peasant levies at Vedla and forced to return to Denmark, while the

castle was destroyed and the archbishop deposed and imprisoned. A second attempt to subdue Sweden in 1518 was also frustrated by Sture's victory at Bränkyrka. A third attempt made in 1520 with a large army of French, German and Scottish mercenaries proved successful. Christian had persuaded Pope Leo X. to excommunicate Sture and to lay Sweden under an interdict. Sture was defeated at Bogesund and mortally wounded at the battle of Tiveden, on Jan. 19, and the Danish army, unopposed, was approaching Uppsala, where the members of the Swedish *Riksråd* had already assembled. The senators consented to render homage to Christian on condition that he gave a full indemnity for the past and a guarantee that Sweden should be ruled according to Swedish laws and custom; and a convention to this effect was confirmed by the king and the Danish *Rigsraad* on March 31. But Sture's widow, Dame Christina Gyllenstjerna, still held out stoutly at Stockholm, and the peasantry of central Sweden, stimulated by her patriotism, flew to arms, defeated the Danish invaders at Balundsås (March 19) and were only with the utmost difficulty finally defeated at the bloody battle of Uppsala (Good Friday, April 6). In May the Danish fleet arrived, and Stockholm was invested by land and sea on Sept. 7. Christina surrendered on the promise of a general amnesty. On Nov. 1, the representatives of the nation swore fealty to Christian as hereditary king of Sweden, and on Nov. 4 he was crowned by Gustavus Trolle in Stockholm cathedral. The next three days were given up to banqueting, but on Nov. 7 "an entertainment of another sort began." On the evening of that day a band of Danish soldiers broke into the great hall and carried off several carefully selected persons. By 10 o'clock the same evening the remainder of the king's guests were safely under lock and key. All these persons were charged with heresy and violence against the church by archbishop Trolle, who presided over their trial on the following day. At 12 o'clock on the night of Nov. 8 the patriotic bishops of Skara and Strängnäs were led out into the great square and beheaded. The executions, known as the "Stockholm bath of blood," continued throughout the following day; in all, about 82 people, most of them noblemen, were thus murdered. Sten Sture's body was dug up and burnt, as well as the body of his little child. Dame Christina and many other noble Swedish ladies were sent as prisoners to Denmark. Christian suppressed his political opponents under the pretence of defending an ecclesiastical system which in his heart he despised.

With his brain teeming with great designs Christian II. returned to his native kingdom. Deeply distrusting the Danish nobles with whom he shared his powers, he sought helpers from among the wealthy middle classes of Flanders. In June 1521 he paid a sudden visit to the Low Countries, and remained there for some months. He visited most of the large cities, took into his service many Flemish artisans, and made the personal acquaintance of Quentin Matsys and Albrecht Dürer, the latter of whom painted his portrait. Christian also entertained Erasmus, with whom he discussed the Reformation, and let fall the characteristic expression: "Mild measures are of no use; the remedies that give the whole body a good shaking are the best and surest." On his return to Denmark on Sept. 5, 1521, Christian proceeded at once to inaugurate the most sweeping reforms. Soon after his return, in 1521 and 1522, he issued his great *Landelove*, or Code of Laws. For the most part this is founded on Dutch models, and testifies in a high degree to the king's progressive aims. Provision was made for the better education of the lower, and the restriction of the political influence of the higher clergy; there were stern prohibitions against wreckers and "the evil and unchristian practice of selling peasants as if they were brute beasts"; the old trade guilds were retained, but the rules of admittance thereto made easier, and trade combinations of the richer burghers, to the detriment of the smaller tradesmen, were sternly forbidden. Unfortunately these reforms, excellent in themselves, suggested the standpoint not of an elected ruler, but of a monarch by right divine. Some of them were even in direct contravention of the charter; and the old Scandinavian spirit of independence was deeply wounded by the preference given to the Dutch.

Sweden too was now in open revolt; and both Norway and

Denmark were taxed to the uttermost to raise an army for the subjection of the sister kingdom. In Jan. 1521 a young Swedish noble, Gustave Eriksson Vasa, at the head of a small force of dalesmen, led a revolt against Christian. (For the ensuing struggle which terminated the union between Denmark and Norway, see GUSTAVUS I. ERIKSSON and SWEDEN: *History*.) On June 6, 1523, Gustavus Eriksson was elected king of Sweden. Foreign complications were added to these domestic troubles. With the laudable object of releasing Danish trade from the grinding yoke of the Hansa, and making Copenhagen the great emporium of the north, Christian had arbitrarily raised the Sound tolls and seized a number of Dutch ships which presumed to evade the tax. Thus his relations with the Netherlands were strained, while with Lübeck and her allies he was openly at war. Finally Jutland rose against him late in 1522, renounced its allegiance and offered the Danish crown to Duke Frederick of Holstein (Jan. 20, 1523). So overwhelming did Christian's difficulties appear that he took ship to seek help abroad, and on May 1 landed at Veere in Zealand. Eight years later (Nov. 1531) he attempted to recover his kingdoms, and obtained some support from Olaf, archbishop of Trondhjem, who feared for the safety of the church under Frederick's rule. Christian landed with a small army of Dutch mercenaries on the Norwegian coast and proclaimed himself king at Oslo (Nov. 29). But he wasted time and opportunities; his fleet was destroyed by a Danish force, and it was arranged that he should negotiate with Frederick in person, on the understanding that if the negotiations broke down he should be allowed to return to Norway. When he reached Denmark, however, he was thrown into prison, first in Sonderborg Castle, afterwards in Kalundborg Castle. He died in Jan. 1559.

See K. P. Arnoldson, *Nordens enhet och Kristian II.* (Stockholm, 1899); Paul Frederik Barfod, *Danmarks Historie fra 1319 til 1536* (1885); *Danmarks Riges Historie*, vol. 3 (1897-1905); R. N. Bain, *Scandinavia*, chap. 2 (Cambridge, 1905). (R. N. B.; X.)

CHRISTIAN III. (1503-1559), king of Denmark and Norway, was the eldest son of Frederick I. of Denmark and his first consort, Anne of Brandenburg. Educated by German Lutheran teachers, Christian travelled in Germany in 1521 and was present at the Diet of Worms. On his return he found that his father had been elected king of Denmark in place of Christian II. Christian's unconcealed Lutheran views brought him into collision with the Catholic *Rigsraad*, and the religious intolerance which he showed in his capacity of stadtholder of the Duchies in 1526, and as viceroy of Norway in 1529, greatly provoked the Catholic party. On the death of Frederick I. in 1533 confusion arose over the election of his successor. Christian was supported by the nobility of Denmark; a strong Catholic party wished to put his younger brother, Hans, who was a child and still a Catholic, on the throne; while the peasants and burghers hoped for the restoration of the captive Christian II. (*q.v.*), and allied themselves with the citizens of Lübeck, who were led by Count Christopher of Oldenburg. Duke Christian crushed the rising of the peasants, made peace with Lübeck and in March 1535 was proclaimed king of Denmark at Viborg.

Christian III.'s triumph brought about the fall of Catholicism. On Aug. 12, 1536, the archbishop and bishops were arrested; on Oct. 30 a national assembly abolished episcopacy, made over the episcopal property to the Crown and established the Lutheran Church in Denmark, with the king as its head. The royal charter issued the same day proclaimed the Crown of Denmark, hitherto elective, hereditary in Christian's line.

The first six years of Christian's reign in Denmark were marked by a contest between the Danish *Rigsraad* and the German counsellors, both of whom sought to rule "the pious king" exclusively. Though the Danish party won a signal victory at the outset, by obtaining the insertion in the charter of provisions stipulating that only native-born Danes should fill the highest dignities of the State, the king's German counsellors continued paramount during the earlier years of his reign. The ultimate triumph of the Danish party dates from 1539, the dangers threatening Christian III. from the emperor Charles V., and other kinsmen of the imprisoned Christian II., compelling him to lean exclusively on Danish mag-

nates and soldiers. The complete identification of the Danish king with the Danish people was accomplished at the *Herredag* of Copenhagen, 1542, when the nobility of Denmark voted Christian a twentieth part of all their property to pay off his heavy debt to the Holsteiners and Germans.

The pivot of the foreign policy of Christian III. was his alliance with the German Evangelical princes, as a counterpoise to the persistent hostility of Charles V., who was determined to support the hereditary claims of his nieces, the daughters of Christian II., to the Scandinavian kingdoms. War was actually declared against Charles V. in 1542, and though the German Protestant princes proved faithless allies, the closing of the Sound against Dutch shipping proved such an effective weapon in King Christian's hand that the Netherlands compelled Charles V. to make peace with Denmark at the Diet of Spiers on May 23, 1544. The foreign policy of Christian's later days was regulated by the Peace of Spiers. He carefully avoided all foreign complications; refused to participate in the Schmalkaldic War of 1546; mediated between the emperor and Saxony after the fall of Maurice of Saxony at the battle of Sievershausen in 1553, and contributed essentially to the conclusion of peace. King Christian III. died on New Year's day, 1559. Though not, perhaps, a great, he was, in the fullest sense of the word, a good ruler. A strong sense of duty, genuine piety and a cautious, but by no means pusillanimous common-sense, coloured every action of his patient, laborious and eventful life. He found Denmark in ruins; he left her stronger and wealthier than she had ever been before.

See *Danmarks Riges Historie*, vol. iii. (Copenhagen, 1897-1901); Huitfeldt, *King Christian III.'s Historie* (Copenhagen, 1595); R. N. Bain, *Scandinavia*, ch. iv., v. (Cambridge, 1905).

CHRISTIAN IV. (1577-1648), king of Denmark and Norway, the son of Frederick II., king of Denmark, and Sophia of Mecklenburg, was born at Fredriksborg castle on April 12, 1577 and succeeded to the throne on the death of his father (April 4 1588); during his minority which lasted till Aug. 17, 1596, the government was carried on by a regency of four. The young king's court was one of the most joyous and magnificent in Europe; yet he found time for work of the most various description, including a series of domestic reforms (see DENMARK: *History*). New fortresses were constructed under the direction of Dutch engineers. The Danish navy was developed and improved. In the war with Sweden, generally known as the "Kalmar War" (see SWEDEN: *History*), Christian compelled Gustavus Adolphus to give way on all essential points (treaty of Knäred Jan. 20, 1613). After this war Christian made efforts to improve the army, which was composed mainly of mercenaries though it was not until after the Thirty Years' War that any effective reforms were carried through. He then turned his attention to Germany. His object was twofold: first, to obtain the control of the great German rivers, the Elbe and the Weser; secondly, to acquire the secularized German bishoprics of Bremen and Werden as appanages for his younger sons. He skilfully took advantage of the alarm of the German Protestants after the battle of White Hill in 1620, to secure the coadjutorship to the see of Bremen for his son Frederick (Sept. 1621), a step followed in November by a similar arrangement as to Werden; while Hamburg by the compact of Steinburg (July 1621) was induced to acknowledge the Danish overlordship of Holstein. The growing ascendancy of the Catholics in North Germany in and after 1621 almost induced Christian, for purely political reasons, to intervene directly in the Thirty Years' War. The solicitations of the Western Powers led him in 1625 to plunge into war against the combined forces of the emperor and the League. For this defeat at Lutteram-Barenberge and the invasion of Jutland by Tilly and Wallenstein see THIRTY YEARS' WAR. In his extremity Christian now formed an alliance with Sweden (Jan. 1, 1628), whereby Gustavus Adolphus pledged himself to assist Denmark with a fleet in case of need, and shortly afterwards a Swedo-Danish army and fleet compelled Wallenstein to raise the siege of Stralsund. Declining to form a further alliance with Sweden for the defence of the North, and of Protestantism, Christian concluded a separate peace on May 12, 1629 with the emperor at Lübeck, without an

diminution of territory, at the price of abandonment of the Protestant cause. Unfortunately Christian would neither conciliate Sweden, henceforth his most dangerous enemy, nor guard himself against her by a definite system of counter-alliances. By mediating in favour of the emperor, after the death of Gustavus Adolphus in 1632, he tried to minimize the influence of Sweden in Germany, and his whole Scandinavian policy was so irritating and vexatious that Swedish statesmen made up their minds to wage war with Denmark. In May 1643 the Swedish *Riksråd* decided upon war; on Dec. 12 the Swedish marshal Lennart Torstensson, advancing from Bohemia, crossed the northern frontier of Denmark; by the end of Jan. 1644 the whole peninsula of Jutland was in his possession. This totally unexpected attack, conducted from first to last with consummate ability and lightning-like rapidity, had a paralysing effect upon Denmark. Yet in his sixty-seventh year Christian IV. once more displayed something of the magnificent energy of his triumphant youth. Night and day he laboured to levy armies and equip fleets. Fortunately too for him, the Swedish government delayed hostilities in Scania till Feb. 1644, so that the Danes were able to make adequate defensive preparations and save the important fortress of Malmö. Torstensson was unable to cross from Jutland to Fünen for want of a fleet, and the Dutch auxiliary fleet which came to his assistance was defeated between the islands of Sylt and Rönne on the west coast of Schleswig by the Danish admirals. Another attempt to transport Torstensson and his army to the Danish islands by a large Swedish fleet under Klas Fleming was frustrated by Christian IV. in person on July 1, 1644. On that day the two fleets encountered off Kolberg Heath, S.E. of Kiel Bay, and Christian displayed a heroism which endeared him ever after to the Danish nation. Darkness at last separated the fleets; and though the battle was a drawn one, the Danish fleet showed its superiority by blockading the Swedish ships in Kiel Bay. But the Swedish fleet escaped, and the annihilation of the Danish fleet by the combined navies of Sweden and Holland at the end of September exhausted the military resources of Denmark and compelled Christian to accept the mediation of France and the United Provinces. Peace was finally signed at Brömsebro in 1645. (See DENMARK: *History*.)

The last years of the king were still further embittered by struggles with the nobility to whom he was forced to concede more and more power. He died at Copenhagen in Feb. 1648. During his reign Norway made great strides in economic and administrative prosperity under his son-in-law, Hannibal Sehested (*q.v.*), as Stadtholder. (See NORWAY: *History*.)

CHRISTIAN V. (1646-1699), king of Denmark and Norway, the son of Frederick III. of Denmark and Sophia Amalia of Brunswick-Lüneburg, was born on April 15, 1646, at Flensburg, and succeeded to the throne on Feb. 9, 1670. Christian was very popular among the lower orders, but hated the old noble families, and tried to establish a new nobility by creating two new orders, consisting largely of officials and upper middle class families, which were to take precedence of the older ones. Under the guidance of his great chancellor Griffenfeldt (*q.v.*), Christian carried his ideas of absolute government into practice, introducing extreme centralization into the organization of civil and military affairs. Griffenfeldt pursued an ambitious policy of foreign alliances, but aimed at keeping peace, and for a brief period Denmark seemed to have a chance of regaining her position as a great power; but Christian sacrificed Griffenfeldt to the jealousy of his adversaries, and sentenced him to life-long imprisonment. After this the financial position of the state grew steadily worse, owing partly to the extravagance of the court, partly to the unremunerative war with Sweden (1675-79). Christian was a weak despot, though his personal courage and affability made him popular among the lower orders. During his reign a new code of laws was drawn up for Norway, begun in 1661 and completed in 1683. He died in a hunting accident on Aug. 25, 1699.

See P. E. Holm, *Danmarks indre Historie under Enevældens* (Copenhagen, 1881-86); A. D. Jørgensen, *Peter Griffenfeldt* (Copenhagen, 1893); R. N. Bain, *Scandinavia* cap. x., xi. (Cambridge, 1905).

CHRISTIAN VII. (1749-1808), king of Denmark and Norway, was the son of Frederick V., king of Denmark, and his first consort Louise, daughter of George II. of Great Britain. He became king on his father's death on Jan. 14, 1766. Badly educated, systematically terrorized by a brutal governor and hopelessly debauched by corrupt pages he grew up a semi-idiot. After his marriage in 1766 with Caroline Matilda (1751-1775), daughter of Frederick, prince of Wales, he abandoned himself to the worst excesses. He ultimately sank into a condition of mental stupor and became the obedient slave of the upstart Struensee (*q.v.*) who, after the dismissal of Bernstorff in 1770, controlled all affairs of State. After the fall of Struensee (the warrant for whose arrest he signed with indifference) in 1772, for the last 26 years of his reign, he was only nominally king, his half-brother, Prince Frederick, acting as regent. He died on March 13, 1808. In 1772 the king's marriage with Caroline Matilda, who had been seized and had confessed to criminal familiarity with Struensee, was dissolved, and the queen, retaining her title, passed her remaining days at Celle in Hanover, where she died on May 10, 1775.

See E. S. F. Reverdil, *Struensee et la cour de Copenhague, 1760-1772* (1858); *Danmarks Riges Historie*, vol. v. (Copenhagen, 1897-1905); and for Caroline Matilda, Sir F. C. L. Wraxall, *Life and Times of Queen Caroline Matilda* (1864), and W. H. Wilkins, *A Queen of Tears* (1904).

CHRISTIAN VIII. (1786-1848), king of Denmark and Norway, the eldest son of the crown prince Frederick and Sophia Frederica of Mecklenburg-Schwerin, was born on Sept. 18, 1786 at Christiansborg castle. His first marriage with his cousin Charlotte Frederica of Mecklenburg-Schwerin was dissolved in 1810. In May 1813 he was sent as stadtholder to Norway to promote the loyalty of the Northmen to the dynasty, which had been very rudely shaken by the disastrous results of Frederick VI.'s adhesion to the falling fortunes of Napoleon. Though his endeavours were opposed by the so-called Swedish party in Norway, which desired a dynastic union with Sweden, he was elected regent of Norway by an assembly of notables on Feb. 16, 1814. This election was confirmed by a *Storting* held at Eidsvold on April 10 and on May 17 Christian was elected king of Norway. On being summoned by the commissioners of the allied powers at Copenhagen to bring about a union between Norway and Sweden in accordance with the terms of the treaty of Kiel, he replied that, as a constitutional king, he could do nothing without the consent of the *Storting*, to the convocation of which a suspension of hostilities on the part of Sweden was the condition precedent. A short campaign ensued, in which Christian was easily worsted by the superior skill and forces of the Swedish crown prince (Bernadotte). The brief war was finally concluded by the convention of Moss on Aug. 14, 1814 (see NORWAY: *History*). Henceforth Christian's alleged democratic principles made him suspect, and he and his second wife, Caroline Amelia of Augustenburg, whom he married in 1815, lived in comparative retirement. It was not till 1831 that old King Frederick gave him a seat in the council of state. On Dec. 13, 1839 he ascended the Danish throne as Christian VIII. The Liberal party had high hopes of "the giver of constitutions," but he disappointed his admirers by steadily rejecting every Liberal project. He came into conflict with the German element in the duchies of Schleswig and Holstein by issuing (March, 1844) a patent permitting, under certain circumstances, the use of the Danish language in the estates. By his Open Letter of July 8, 1846, in which he declared that the *Kongelov*, Danish royal law in the matter of the succession applied to Schleswig and Lauenburg, though its application to parts of Holstein was doubtful, and by the Constitution of Jan. 28, 1848, he raised the Schleswig-Holstein question in a form which involved his successor in the War of 1848. (See SCHLESWIG-HOLSTEIN QUESTION.) He died at Plön on Jan. 20, 1848.

See Just Matthias Thiele, *Christian den Ottende* (Copenhagen, 1848); Yngvar Nielsen, *Bidrag til Norges Historie* (Christiania, 1882-86); A. J. Lange, *Christian Frederik som Norges Statholder regent og Konge* (1914).

CHRISTIAN IX. (1818–1906), king of Denmark, was a younger son of William, duke of Schleswig-Holstein-Sonderburg-Glücksburg (d. 1831), a direct descendant of the Danish king Christian III. by his wife Louise, a daughter of Charles, prince of Hesse-Cassel (d. 1836), and grand-daughter of King Frederick V. Born at Gottorp on April 8, 1818, Christian entered the army, and served with the Danish troops in Schleswig during the insurrection of 1848. In 1842 he married Louise (1817–1898), daughter of William, prince of Hesse-Cassel (d. 1867), and cousin of King Frederick VII. The reigning king, Frederick VII., being childless, the representatives of the great powers met in London and settled the crown on Prince Christian (May 1852), an arrangement confirmed in Denmark in 1853. The "protocol king," as Christian was sometimes called, ascended the throne on Frederick's death in Nov. 1863. By putting into force (Nov. 18) the recently drafted constitution under which Schleswig was to be incorporated with Denmark, he came into conflict with the German confederation. (See SCHLESWIG-HOLSTEIN QUESTION.) The German-Danish War followed, which ended by the separation (Oct. 13, 1864) of the duchies from Denmark. Within the narrowed limits of his kingdom Christian's difficulties were more protracted and hardly less serious. During almost the whole of his reign the Danes were engaged in a political struggle between the "Right" and the "Left," the former being supported in general by the *Landsting*, and the latter by the *Folketing*. The king was for many years successful in preventing the Radicals from coming into office, but in 1901 he was forced to assent to the formation of a "cabinet of the Left" (see DENMARK: History). In his later years he occupied a patriarchal position among the sovereigns of Europe to many of whom he was related. His eldest son Frederick had married a daughter of Charles XV. of Sweden; his second son George had been king of the Hellenes since 1863; and his youngest son Waldemar (b. 1858) was married to Marie d'Orléans, daughter of Robert, duc de Chartres. Of his three daughters, Alexandra married Edward VII. of Great Britain; Dagmar (Marie Feodorovna), the tsar Alexander III.; and Thyra, Ernest Augustus, duke of Cumberland. One of his grandsons, Charles, who married Princess Maud of England, became king of Norway as Haakon VII. in 1905, and another, Constantine, crown prince (afterwards king) of Greece, married a sister of the German emperor William II. Christian was also the ruler of Iceland. He died at Copenhagen on Jan. 29, 1906, and was buried at Roskilde.

See Barfod, *Kong Kristian IX's Regerings-Dagbog* (Copenhagen, 1876); and Hans Majestet Kong Kristian IX. (Copenhagen, 1888).

CHRISTIAN X., King of Denmark and Iceland (1870–), was born on Sept. 26, 1870, at Charlottenlund Castle, near Copenhagen, the eldest son of Crown Prince Frederik, later King Frederik VIII. (1906–12), and Louise, Princess of Sweden and Norway. After matriculating in 1889, the prince embarked upon a military career, becoming chief of the royal guard, and attained the rank of major-general. He married, in 1898, Alexandrine, duchess of Mecklenburg-Schwerin. In 1906 he became Crown Prince and in 1912 ascended the throne.

During the World War the necessity of friendly intercourse between the Scandinavian kingdoms resulted in several meetings between the three kings, of which the first was held at Malmö in Dec. 1914. On June 5, 1915 King Christian signed the new constitution of Denmark which extended the franchise to women. He signed, on Dec. 1, 1919, the Federal Act, whereby Denmark acknowledged Iceland as an independent kingdom and King of Iceland was incorporated in the King's title. In July 1920 he rode over the old frontier into Slesvig Nord, which had been ceded to Denmark by the Treaty of Versailles, and received an enthusiastic reception from the people. In 1921 the king and queen and their two sons, Crown Prince Frederik (b. 1899) and Prince Knud (b. 1900) journeyed to Iceland and the west coast of Greenland. King Christian, by moving freely among the people, increased his popularity with all classes.

CHRISTIAN, WILLIAM (1608–1663), Manx politician, a son of Ewan Christian, one of the Manx deemsters, was born on April 14, 1608, and was known as *Illiam Dhone*, or Brown Wil-

liam. In 1648 the lord of the Isle of Man, James Stanley, 7th earl of Derby, appointed Christian his receiver-general; and when in 1651 the earl crossed to England to fight for Charles II. he left him in command of the island militia. Derby was taken prisoner at the battle of Worcester, and his famous countess Charlotte de la Tremouille, who was residing in Man, sought to obtain her husband's release by negotiating with the victorious parliamentarians for the surrender of the island. At once a revolt headed by Christian broke out, partly as a consequence of this step, partly owing to the discontent caused by some agrarian arrangements recently introduced by the earl. The rebels seized many of the forts; then Christian in his turn entered into negotiations with the parliamentarians; and probably owing to his connivance the island was soon in the power of Col. Robert Duckenfield, who had brought the parliamentary fleet to Man in Oct. 1651. The countess of Derby was compelled to surrender her two fortresses, Castle Rushen and Peel Castle, while Christian remained receiver-general, becoming governor of the island in 1656. Two years later, however, he was accused of misappropriating some money; he fled to England, and in 1660 was arrested in London. Having undergone a year's imprisonment he returned to Man, hoping that his offence against the earl of Derby would be condoned under the Act of Indemnity of 1661; but, anxious to punish his conduct, Charles, the new earl of Derby, ordered his seizure; he refused to plead, and a packed House of Keys declared that in this case his life and property were at the mercy of the lord of the island. The deemsters then passed sentence, and in accordance therewith Christian was shot on Jan. 2, 1663. This arbitrary act angered Charles II. and his advisers; the deemsters and others were punished, and some reparation was made to Christian's family. Christian is chiefly celebrated through the Manx ballad *Baase Illiam Dhone*, which was translated into English by George Borrow, and through the reference to him in Sir Walter Scott's *Peveril of the Peak*.

See A. W. Moore, *History of the Isle of Man* (1900).

CHRISTIAN CATHOLIC CHURCH, the name assumed by a religious organization founded at Zion City (q.v.) near Chicago, Ill., in 1896, by John Alexander Dowie (q.v.). Its members added to the usual tenets of Christianity a special belief in faith-healing, and laid much stress on united consecration services and the threefold immersion of believers. To assist Dowie, assistant overseers were appointed, and the operations of the community included religious, educational and commercial departments. After 1903 considerable dissension arose among Dowie's followers: he was deposed in 1906; and after his death in 1907 his assistant Wilbur Glenn Voliva became general overseer of the organization.

See art. "Enthusiasts (religious)," by G. H. Gray and W. T. Whitley in Hastings, *Encyclopædia of Religion and Ethics*, vol. v. p. 320; and K. Harlan, *John Alexander Dowie and the Christian Catholic Church*, Evansville, Wisconsin, 1906.

CHRISTIAN CONNECTION, a denomination of Christians in North America formed by secession, under James O'Kelly (1735–1826), of members of the Methodist Episcopal Church in North Carolina in 1793. The predisposing cause was the desire to be free from the "bondage of creed." Some of O'Kelly's followers joined the Disciples of Christ (q.v.). Their form of church government is Congregational; they take the Bible as the sole rule of faith and practice, and while adopting immersion as the proper mode of baptism, freely welcome Christians of every sect to their communion. Their position is curiously akin to that outlined by William Chillingworth (q.v.) in his famous work *The Religion of Protestants* (1637–1638).

CHRISTIAN ENDEAVOUR SOCIETIES, organizations formed for the purpose of promoting spiritual life among young people. They date from 1881, in which year Dr. Francis E. Clark (q.v.) formed a Young People's Society of Christian Endeavour in his (Congregational) church at Portland, Maine, U.S.A. The idea was taken up elsewhere in America and spread to other countries, till, under the presidency of Dr. Clark, a huge number of affiliated societies came into operation throughout the world. They take as their motto "For Christ and the Church," and have done much, especially in the non-episcopal churches, to prepare

young men and women for active services in the Church. The organization is international and interdenominational, a World's Christian Endeavour Union being formed in 1895.

See Francis E. Clark, art. "Christian Endeavour," in *Hastings' Encyclopedia of Religion and Ethics*, vol. iii, 571 ff. (with ref.) and *Memories of Many Men in Many Lands* (1922); J. R. Fleming, *The Christian Endeavour of the Future* (1903).

CHRISTIANIA, the capital of Norway; see OSLO.

CHRISTIANITY, regarded historically as one of the great religions of the world, owes its rise to Jesus of Nazareth, in ancient Galilee (see JESUS CHRIST). By reverent disciples His ancestry was traced to the royal family of David and His birth is ascribed by the church to the miraculous act of God. At 30 years of age Jesus Christ appeared in public, and after a short period (we cannot determine how long, but possibly 18 months) he was crucified, upon the accusation of His countrymen, by the Roman authorities.

Relation to Judaism.—His career is understood only in the light of His relation to Judaism (see HEBREW RELIGION). This faith, in a peculiarly vivid fashion, illustrates the growth and development of religion, for its great teachers in the highest degree possessed what the Germans call God-consciousness. When the national independence of Israel was destroyed, the prophetic teaching held the people together in the hope of a re-establishment of the Kingdom when all nations should be subject to it and blessed in its everlasting reign of righteousness and peace (Isa. xlix, lx.).

Some of the prophets associated the restoration of the Kingdom with the coming of the Messiah, the anointed one, who should re-establish the line of David (Isa. ix. 6 f., xi. 1 f.; Micah v. 2; Ezek. xxxiv. 23, xxxvii. 24; Zech. ix. 9; Ps. ii. 72). Others said nothing of such a one, but seemed to expect the regeneration of Israel through the labours, sufferings and triumphs of the righteous remnant (Isa. liii., Ezek. xxxvi.—xxxvii.). By the strong emphasis upon righteousness, the tribal Lord of Israel was revealed as the universal God, of one relationship to all men. This monotheism was not primarily cosmological nor metaphysical, but ethical. The Jews showed little capacity for abstract reasoning and never pursued their inquiries to the discovery of ultimate principles. Thus they did not develop a systematic cosmology, nor formulate a system of metaphysics. Their religion was pre-eminently "theocratic"; God was thought of as King, enthroned in heaven and supreme.

But the prophetic teaching was obscured in part by the nationalism of the prophets themselves, who exalted Israel as at once God's instrument and the peculiar object of His love. Inevitably the freedom, spirituality and universality of the prophetic teaching were obscured. In the 1st century A.D. the national and priestly elements were supreme. The triumph of Israel was to be accomplished by the miraculous power of a Messiah who should descend out of heaven. His coming was delayed, in part by the opposition of demons, in part by the failure of the people to obey the law, which embraced both moral and ceremonial elements derived from varied sources, but by the people was all alike regarded as of divine origin. It was to be obeyed without question and without inquiry as to its meaning, because established by God; it was contained in the Sacred Scriptures (see BIBLE: *Old Testament*), which had been revealed by God supernaturally, and its meaning was set forth by schools of learned men whose interpretations were authoritative. The priesthood held still the ancient ideas. Salvation was for the nation, and the individual was not necessarily participant in it; life after death was disbelieved or held as the existence of shades; there could be no resurrection of the body and no immortality (in the Greek sense); and with these beliefs were associated a certain worldliness and want of fervour. The more actively and aggressively religious party, on the other hand, adopted the belief in the resurrection of the body, and in the individual's participation in the Messiah's kingdom; all the pious would have their share in it, while the wicked would be outcast. But these doctrines were variously conceived. By some the Messianic kingdom was thought of as permanent, by others as intermediary, the external kingdom being transcendent.

So too some thought of a literal resurrection of the body of flesh and blood, while others thought that it would be transformed. The rudiments of some of these ideas can be found in the prophets, but their development took place after the exile, and indeed for the most part after the conclusion of the writings accounted canonical. Thus too the belief in a kingdom of demons held a large place in the mind of the people, though the references to such evil beings are almost absent from the sacred writings of the Old Testament. Again it is to the East that we must look for the origin of these ideas.

The Teaching of Jesus.—Jesus completed the prophetic teachings. He employed the old phraseology and imagery, but He was conscious that He used them in a new sense, and that He preached a new gospel of great joy. Jesus was not a historian, a critic or a theologian. He used the words of common men in the sense in which common men understood them; He did not employ the Old Testament as now reconstructed by scholarship or judged by criticism, but in its simple and obvious and traditional sense, and His background is the intellectual and religious thinking of His time. The ideas of demons and of the future, of the Bible and many other traditional conceptions, are taken over without criticism. So the idea of God which He sets forth is not that of a theologian or a metaphysician, but that of the unlearned man which even the child could understand. Yet though thus speaking in untechnical language, He revolutionized His terms and filled them with new meaning. His emphasis is His own, and the traditional material affords merely the setting for His thought. He was not concerned with speculative questions about God, nor with abstract theories of His relationship to the soul and to the world. God's continual presence, His fatherly love, His transcendent righteousness, His mercy, His goodness, were the facts of immediate experience; not in proofs by formal logic but in the reality of consciousness was the certainty of God. Thus religion was freed from all particular and national elements in the simplest way: for Jesus did not denounce these elements, nor argue against them, nor did He seek converts outside Israel, but He set forth communion with God as the most certain fact of man's experience and as simple reality made it accessible to everyone. Thus His teaching contains the note of universality—not in terms and proclamations but as plain matter of fact. His way for others to this reality is likewise plain and level to the comprehension of the unlearned and of children.

For Him repentance (change of mind, *μετάνοια*) is placed first. The intricacies of ritual and theology are ignored, and ancient laws which contradict the fundamental beliefs are unhesitatingly abrogated or denied. He seizes upon the most spiritual passages of the prophets, and revives and deepens them; He sums up His teaching in supreme love to God and a love for fellow-man like that we hold for ourselves (Mark xii. 29–31). This supreme love to God is a complete oneness with Him in will, a will which is expressed in service to our fellow-men in the simplest and most natural relationship (Luke x. 25–37). Thus religion is ethical through and through, as God's inner nature, expressed in forgiveness, mercy, righteousness and truth, is not something transcendental, but belongs to the realm of daily life. We become children of God and He our Father in virtue of a moral likeness (Matt. v. 43–48), while of any metaphysical or (so to speak) physical relationship to God, Jesus says nothing. With this clearly understood, man is to live in implicit trust in the divine love, power, knowledge and forgiveness. Hence he attains salvation, being delivered from sin and fear and death, for the divine attributes are not ontological entities to be discussed and defined in the schools, but they are realities, entering into the practical daily life. Indeed they are to be repeated in us also, so that we are to forgive our brethren as we ask to be forgiven (Matt. vi. 12; Luke xi. 4).

As religion thus becomes thoroughly ethical, so is the notion of the Messianic kingdom transformed. Its essential characteristic is the doing of the Father's will on earth as in heaven. Jesus uses parable after parable to establish its meaning. It is a seed cast into the ground which grows and prospers (Matt. xiii. 31–32); it is a seed sown in good ground and bringing forth

fruit, or in bad ground and fruitless (Luke viii. 5-8; Mark iv. 1-32); it is a pearl of great price for which a man should sell all that he possesses (Matt. xiii. 44-46); it is not come "with observation," so that men shall say "lo here and lo there" (Luke xvii. 20-21); it is not of this world, and does not possess the characteristics or the glory of the kingdom of the earth (Luke xxii. 24-26; Mark x. 13-16); it is already present among men (Luke xvii. 21). Together with these statements in our sources are still mingled fragments of the more ordinary cataclysmic, apocalyptic conceptions, which in spite of much ingenious exegesis, cannot be brought into harmony with Christ's predominant teaching, but remain as foreign elements in the words of the Master, possibly brought back through His disciples, or, more probably, used by Jesus uncritically—a part of the current religious imagery in which He shared.

Originality.—It is often declared that in these teachings there is nothing new, and indeed analogies can be found for many sayings; yet nowhere else do we gain so strong an impression of originality. The net result is not only new but revolutionary; so was it understood by the Pharisees. They and Jesus spoke indeed the same words and appealed to the same authorities, but they rightly saw in Him a revolutionist who threatened the existence of their most cherished hopes. The Messianic kingdom which they sought was opposed point by point to the kingdom of which He spoke, and their God and His Father—though called by the same sacred name—were different. Hence almost from the beginning of His public ministry they constantly opposed Him, the conflict deepening into complete antagonism.

Jesus Christ has been termed unique, one of the common people yet separated from them, and this description applies to the breadth, depth and reality of His sympathy. In the meagre records of His life there is evidence that He deemed no form of suffering humanity foreign to Himself. This was not a mere sentiment, nor was His sympathy superficial, for it constituted the essential characteristic of His personality—"He went about doing good." In Him the will of the Father for the redemption of the race was incarnate. This led Him into the society of those outcasts who were condemned and rejected by the respectable and righteous classes. In contemptuous condemnation He was called the friend of the outcasts (Matt. xi. 19; Mark ii. 16-17), and on His part He proclaimed that these sinners would enter into the Kingdom of Heaven before the self-righteous saints (Matt. xxi. 31); even the most repulsive forms of disease and sin drew from Him only loving aid, while he recognized in all other men who laboured for the welfare of their fellows the most intimate relationship to Himself; these constituted His family, and these were they whom His Father will bless.

Jesus recognized His unique position; He could not be ignorant of His powers. Even the prophets had spoken in the name of God; they accepted neither book nor priesthood as authoritative, but uttered their truth as they were inspired to speak, and commanded men to listen and obey. As in Jesus the whole prophetic line culminates, so does its consciousness; reverent toward the Holy Scriptures, He spoke not as their expositor but with a power which invests His words with immediate and full authority. The prophets used the formula, "Thus saith the Lord," but He goes beyond them and speaks in His own name. He believed Himself to be the Messiah of whom the prophets spoke, and only through this self-consciousness can we explain His mission and the career of His disciples. The prophets up to John foretold the coming of the kingdom (Matt. xi. 11-13; Luke xvi. 16), but Jesus opened its doors and made possible entrance into it. Where He is there it is, and hence those who follow Him are God's children, and those who refuse His message are left outside in darkness. He is to sit as enthroned, judge and king, and by Him is men's future to be determined (Matt. xxv. 31 f.; Mark xiii. 26); indeed it was His presence more than His teaching which created His Church. Great as were His words, greater was His personality. His disciples misunderstood what He said, but they trusted and followed Him. By Him they felt themselves freed from sin and fear—and under the influence of a divine power.

Messianic Claims.—Though His claims to authoritative pre-

eminence thus took Him out of the class of prophets and put Him even above Elijah and Moses (Mark ix. 2-7; Luke vii. 28; Luke x. 23-24), and though naturally this self-assertion seemed blasphemous to those who did not accept Him, yet as He had transformed the traditional notion of the kingdom, so did He the current thought of the Messiah. The pre-eminence was not to be of rank and glory but of service and self-sacrifice. In His kingdom there can be no strife for precedence, since its King comes not to be ministered unto but to minister and to give His life in the service of others (Mark ix. 33 f., x. 42-45). The formal acknowledgment of the Messiah's worth and position matters little, for to call Him Lord does not ensure entrance into His Kingdom (Matt. vii. 21-23). It is those who fail to recognize the spirit of sympathy and self-sacrificing service as divine and blasphemy re-deeming love who are in danger of eternal sin (Mark iii. 28-29). All who do the will of the Father, *i.e.*, who serve their fellows, are the brethren of Christ, even though they do not call Him Lord (Mark iii. 31-35; Matt. vii. 21): and those are blessed who minister to the needy even though ignorant of any relation to Himself (Matt. xxv. 37-40). Finally, membership in His own selected company, or a place in the chosen people, is not of prime importance (Mark ix. 38-40; Luke xiii. 24-30).

Jesus also refuses to conform to the current ideas as to the establishment of the kingdom. The tradition of the people implied a sudden appearance of the Messiah, but Jesus made no claims to a supernatural origin and was content to be known as the son of Joseph and Mary (Mark vi. 3-4). His kingdom is not to be set up by wonders and miraculous powers, nor is it to be established by force (Matt. xxvi. 52); such means would contradict its fundamental character, for as the kingdom of loving service it can be established only by loving service. Even the disciples of Jesus could not grasp the simplicity and profundity of His message; still less could His opponents. He was accused of blasphemy to the ecclesiastical authorities and of insurrection to the civil rulers. He was condemned and crucified. His followers were scattered. Of His work nothing remained, not a written word, nor more than the rudiments of an organization. The decisive event, which turned defeat into victory and re-established courage and faith, was the belief in the reappearance to His disciples. Our sources will not permit the precise determination of the order or the nature of these appearances, but in any case from them arose the faith which was the basis of the Christian Church and the starting-point of its theology.

The death of Jesus as a criminal, and His resurrection, profoundly aroused the belief and hopes of the little group of Jews who were His followers. It is not His word but His person which assumes first place, and faith is acceptance of Him—crucified and risen—as Messiah. Hence His followers early acquire the name Christian from the Greek form of the word. With this emphasis upon the Messiah the Jewish element would seem to be predominant, but as a matter of fact it was not so. The earlier group of disciples, it is true, did not appreciate the universality of the teaching of Jesus, and they continued zealous for the older forms; but Paul through his prophetic consciousness grasped the fundamental fact and in this respect became Jesus' true interpreter. As a result Christianity was rejected by the Jews and became the conquering religion of the Roman empire. In this it underwent another modification of far-reaching consequence.

In our earliest sources—the epistles of St. Paul—Christ is the pre-existent divine man from heaven, He is before and above all things, and had come to earth by a voluntary act of self-humiliation. In the Johannine writings He is the Son of God—the Logos who in the beginning was with God—of Whom are all things—Who lightens every man—and Who was incarnate in Jesus. Here the cosmological element is again made prominent though not yet supreme, and the metaphysical problems are so close at hand that their discussion is imperative. Even in Paul the term Messiah thus had lost its definite meaning and became almost a proper name. Among the Greek Christians this process was complete. Jesus is the "Son of God"; and the great problem of theology becomes explicit. Religion is in our emotions of reverence

and dependence, and theology is the intellectual attempt to describe the object of worship. Doubtless the two do not exactly coincide, not only because accuracy is difficult or even impossible, but also because elements are admitted into the definition of God which are derived from various sources quite distinct from religious experience. Like all concepts the meaning of religious terms is changed with a changing experience and a changing world-view. Transplanted into the world where Greek ideas were prevalent, inevitably the Christian teaching was modified—indeed transformed. Questions which had never been asked came into the foreground, and the Jewish presuppositions tended to disappear, and the Messianic hopes were forgotten or transferred to a transcendent sphere beyond death. When the empire became Christian in the 4th century, the notion of a kingdom of Christ on earth to be introduced by a great struggle all but disappeared, remaining only as the faith of obscure groups. As thus the background is changed from Jewish to Greek, so are the fundamental religious conceptions.

The Semitic peoples were essentially theocratic; they used the forms of the sensuous imagination in setting forth the realities of the unseen world. They were not given to metaphysical speculation, nor long insistent in their inquiries as to the meaning and origin of things. With the Greeks it was far otherwise: for them ideas and not images set forth fundamental reality, and their restless intellectual activity would be content with nothing but the ultimate truth. Their speculation as to the nature of God had led them gradually to separate Him by an infinite distance from all creation, and to feel keenly the opposition of the finite and the infinite, the perfect and the imperfect, the eternal and the temporal. To them, therefore, Christianity presented itself not primarily as the religion of a redemption through the indwelling power of a risen Saviour, as with Paul, nor even as the solution of the problem how the sins of men could be forgiven, but as the reconciliation of the antinomy of the intellect, indicated above. The incarnation became the great truth: God is no longer separated by a measureless distance from the human race, but by His entering into humanity He redeems it and makes possible its ultimate unity with Himself. Such lines of thought provoke discussion as to the relationship of Jesus to God the Father, and, at a later period, of the nature of the Holy Spirit who enters into and transforms believers.

Greek philosophy in the 2nd century A.D. had sunk for the most part into scepticism and impotence; its original impulse had been lost, and no new intellectual power took its place; only in Alexandria was there a genuine effort made to solve the fundamental problems of God and the world; and mingled with the speculations of the Greek philosophers were the ancient legends of gods and heroes, accepted as inspired scripture by the people, and by the philosophers in part explained away by an allegorical exegesis and in part felt increasingly as a burden to the intelligence. In this period of degeneracy there were none the less an awakening to religious needs and a profound longing for a new revelation of truth, which should satisfy at once the intellect and the religious emotions.

Christianity came as supplying a new power; it freed philosophy from scepticism by giving a definite object to its efforts and a renewed confidence in its mission. Monotheism henceforth was to be the belief not of philosophers only but even of the ignorant, and in Jesus Christ the union of the divine and the human was effected. The Old Testament, allegorically explained, became the substitute for the outgrown mythology; intellectual activity revived; the new facts gained predominant influence in philosophy, and in turn were shaped according to its canons. In theology the fundamental problems of ontological philosophy were faced; the relationship of unity to multiplicity, of noumenon to phenomena, of God to man. The new element is the historical Jesus, at once the representative of humanity and of God. As in philosophy, so now in theology, the easiest solution of the problem was the denial of one of its factors: and successively these efforts were made, until a solution was believed to be found which satisfied both terms of the equation and became the fundamental creed of the Church. Its moulds of thought are those

of Greek philosophy, and into these were run the Jewish teachings. We have thus a peculiar combination—the religious doctrines of the Bible, as culminating in the person of Jesus, run through the forms of an alien philosophy.

The Doctrine of the Trinity.—The Jewish sources furnished the terms Father, Son and Spirit. Jesus seldom employed the last term and Paul's use of it is not altogether clear. Already in Jewish literature it had been all but personified (*cf. the Wisdom of Solomon*). Thus the material is Jewish, though already doubtless modified by Greek influence: but the problem is Greek; it is not primarily ethical nor even religious, but it is metaphysical. What is the ontological relationship between these three factors? The answer of the Church is given in the Nicene formula, which is characteristically Greek, and which affirms that God, the infinite, the absolute, the eternal, is yet not separated from the finite, the temporal, the relative, but, through the incarnation, enters into humanity (*see ARIANISM; ATHANASIUS*). This entering into humanity is not an isolated act but continues in all the children of God by the indwelling Spirit. Thus, according to the canons of ancient philosophy, justice is done to all the factors of our problem—God remains as Father, the infinitely remote and absolute source of all; as Son, the Word Who is revealed to man and incarnate in Him; as Spirit, Who dwells even in our own souls and by His substance unites us to God.

Jesus was the central fact of faith, because he had led the disciples to God. After the resurrection He was the object of praise, and soon prayers were offered in His name and to Him. Already to the apostle Paul He dominates the world and is above all created things, visible and invisible, so that He has the religious value of God. Metaphysics and speculative theories were valueless for Paul; he was conscious of a mighty power transforming his own life and filling him with joy, and that this power was identical with Jesus of Nazareth he knew. In all this Paul is the representative of that which is highest and best in early Christianity. Speculation and hyperspiritualization were ever tending to obscure this fundamental religious fact: in the interest of a higher doctrine of God His true presence in Jesus was denied, and by exaggeration of Paul's doctrine of "Christ in us" the significance of the historic Jesus was given up. The Johannine writings, which presupposed the Pauline movement, are a protest against the hyperspiritualizing tendency. They insist that the Son of God has been incarnate in Jesus of Nazareth, and that our hands have handled and our eyes have seen the word of life. This same purpose, namely, to hold fast to the historic Jesus, triumphed in the Nicene formula; Jesus was not to be resolved into an aeon or into some mysterious *tertium quid*, neither God nor man, but to be recognized as very God who redeemed the soul. Through Him men were to understand the Father and to understand themselves as God's children.

It is apparent that such a doctrine as the Trinity is itself susceptible of many explanations, particularly as to the distinction and relation between God the Eternal Son and God the Holy Spirit; and minds differently constituted lay emphasis upon its different elements. Especially is this true as its Greek terminology was translated into Latin, and from Latin came into modern languages—the original meaning being obscured or disguised, and the original issues forgotten. For some the first thought of God, the infinite and ultimate reality lying beyond and behind all phenomena, predominates. With these the historic manifestation of Jesus becomes only a guide to lead us to that immediate apprehension of God which is the end of theology, and to that immediate union with God which is the end of religion. Such an end is accomplished either by means of pure thought or by a oneness of pure feeling, giving as results the theological or philosophical construction of the idea of God, or a mystical ecstasy which is itself at once immediate, inexplicable and indescribable. On the other hand, minds of a different and more concrete character so emphasize the distinctions God, Son and Holy Spirit, that a tritheistic construction appears—three individuals in the one Godhead: these individuals appearing, as for example, in the Father and the Son, even in opposition to each other. In general we may say then that the Trinity takes on

three differing aspects in the Christian Church: in its more common and easily apprehended form as three Gods; in its ecclesiastical form as a mystery which is above reason to be accepted by faith; in its philosophic form as a metaphysical interpretation of the finite, the infinite and the relation between them.

To some Christians the doctrine of the Trinity appeared inconsistent with the unity of God which is emphasized in the Scriptures. They therefore denied it, and accepted Jesus Christ, not as incarnate God, but as God's highest creature by Whom all else was created, or as the perfect man who taught the true doctrine of God. The first view in the early Church long contended with the orthodox doctrine, but finally disappeared, and the second doctrine in the modern Church was set forth as easily intelligible, but has remained as a form of "heresy."

The Cross and the Atonement.—Allied with the doctrine of God which seeks the solution of the ultimate problem of all philosophy, the doctrine of salvation has taken the most prominent place in the Christian faith: so prominent, indeed, that to a large portion of believers it has been the supreme doctrine, and the doctrine of the deity of Jesus has been valued only because of its necessity on the effect of the atonement. Jesus alone of the great founders of religion suffered an early and violent death, even the death of a criminal. It became therefore the immediate task of His followers to explain this fact. This explanation was the more urgent because under the influence of Jewish monotheism the rule of God was accepted as an undoubted presupposition, so that the death of Jesus must be in accordance with His will. The early Church naturally used the term and phrases of the prophets. He died the death of a criminal, not for His sins, but for ours. Isaiah liii. was suggested at once and became the central explanation: Christ is the suffering servant Who is numbered with the transgressors and Who bears the sins of many.

It is remarkable that in the earliest centuries of Christian thought there is only the most slender support for theories of the Atonement which became widely current at a later time. The early Fathers did not regard the sufferings of Christ as a vicarious satisfaction of God's wrath, where He underwent punishment due to us and His obedience is imputed to us. Whenever they use language which seems to convey such ideas, they as it were instinctively safeguard it by the idea of our union with Christ, where we share in His obedience and His passion, and only so far as we make them our own do we actually appropriate the redemption He won for us. Their main thought is that man is reconciled to God by the Atonement, and not God to man; the change which it effects is a change in man rather than a change in God. Many centuries later the familiar outlines of the theory of vicarious atonement were drawn, and carved into a rigid scheme by the Reformers. They were deeply convinced that human sin is the violation of an eternal law which has its basis in the very being of God and is the expression of God's justice, which must be satisfied. This is the conviction embodied in the Protestant creeds, and worked out by means of metaphors so legal and even mechanical in character that modern theology has been marked by a widespread revolt against every form of it.

A large part of the history of Christian doctrine deals with controversies arising from theories of the Atonement (*q.v.*); but excepting in relatively narrow circles these theories have been seriously studied only by professed theologians. That Christ died for us, and that we are saved by Him, is indeed the living truth of the Church in all ages, and a false impression of the fact is given by dwelling upon theories as if they were central. At best they bear only the relationship of philosophy to life.

These hopes and theories of salvation do not indeed wholly explain the power of Christianity. Jesus wearied Himself with the healing of man's physical ailments, and He was remembered as the great physician. Early Christian literature is filled with medical terms, applied (it is true) for the greater part to the cure of souls. The records of the Church are also filled with the efforts of Jesus's followers to heal the diseases and satisfy the wants of men. A vast activity animated the early Church: to heal the sick, to feed the hungry, to succour the diseased, to rescue the fallen, to visit the prisoners, to forgive the erring, to teach the

ignorant, were ministries of salvation. A mighty power impelled men to deny themselves in the service of others, and to find in this service their own true life. None the less the first place is given to the salvation of the soul, since, created for an unending existence, it is of transcendent importance. While man is fallen and by nature vile, nevertheless his possibilities are so vast that in comparison the affairs of earth are insignificant. The word, "What shall it profit a man if he gain the whole world and lose his own soul?" comes to mean that the individual soul outvalues the whole world. With emphasis upon God as creator and ruler, and upon man as made in God's image, endowed with an unending existence, and subject to eternal torture if not redeemed, the concept of personality has been exalted at the expense of that of nature, and the future has been magnified at the expense of the present. Thus a future heaven is man's true home, and theology instead of philosophy or natural science is his proper study.

Indeed, intellectual interest centred in religion. Natural science was forsaken, except in so far as it ministered to theology. Because the Old Testament contained references to the origin and the objects of the universe, a certain amount of natural science was necessary, but it was only in this connection that it had any value. By Augustine's time this process is complete. His writings contain most of the knowledge of his age, but it is strictly subordinate to his theological purpose. Hence, when the barbarians submerged southern Europe, theology alone survived. The Church entered upon a new task. In the beginning Christianity had been the teacher of religion to highly civilized peoples—now it became the civilizing agent to the barbarians, the teacher of better customs, the upholder of law and the source of knowledge. The learned men were monks and priests, and the universities were Church institutions.

The Sacraments and Salvation.—Belief in mysterious powers attached to food, feasts, ceremonial rites and sacred things is all but universal. Primitive man seldom connects sacrifice with notions of propitiation, indeed only in highly ethicized religions is the consciousness of sin or of guilt pre-eminent. Sacrifice was believed to exert an influence on the deity which is quasi-physical, and in sacrificial feasts God and worshipper are in mysterious union.

So universal are such ideas that the problem in particular religions is not their origin but their form. In the Old Testament repeatedly they are found in conflict with the prophetic ideals. Sometimes the prophets denounce them, sometimes ignore them sometimes attempt to reform and control them. Jesus ignores them, His emphasis being so strong upon the ethical and spiritual that the rest is passed by. In the early Church, still Jewish, the belief was in the coming of a mysterious power from God which produced ecstasy and worked wonders. Paul also believes in this but insists that it is subordinate to the peaceable fruits of righteousness. With the naturalization of the Church in the Gentile world ethical ideas became less prominent, and the sacramental system prevailed. By baptism and the Lord's Supper grace is given (*ex opere operato*), so that man is renewed and made capable of salvation. Already in the 2nd century baptism was described as a bath in which the health of the soul is restored, and the Lord's Supper as the potion of immortality. Similar notions present in the ethnic faiths take the Christian facts into their service, the belief of the multitude without essential change remaining vague and undefined. While the theologians discussed doctrine the people longed for mystery, as it satisfied their religious natures; by sacraments they felt themselves brought into the presence of God, and to sacraments they looked for aid. Many sacraments were adopted by portions of the Church, until at last the sacred number seven was agreed upon.

In the earliest period the services were characterized by extreme freedom, and by manifestations of ecstasy which were believed to indicate the presence of the spirit of God; but as time went on the original enthusiasm faded away, the cult became more and more controlled, until ultimately it was completely subject to the priesthood, and through the priesthood to the Church. The power of the priesthood had its centre in the sacrament of the Eucharist (*q.v.*), and in the Roman communion the structure of

the sacred edifice, the positions and attitudes of the priest and the congregation, the order of service, emphasize the mystery and the divine efficacy of the sacrament. The worshipper feels himself in the immediate presence of God, and enters into physical relations with him; participation in the mass also releases from guilt, as the Lamb of God offered up atones for sin and intercedes with the Father in our behalf. Thus in this single act of devotion both objects of all cults are attained.

Organization.—As the teaching and person of Jesus were fitted into the framework of Greek philosophy, and the sacraments into the deeper and broader forms of popular belief, so was the organization shaped by the polity of the Roman empire. Jesus gathered His group of followers and committed to it His mission, and after His resurrection the necessities of the situation brought about the choice of quasi-officials. Later the familiar polity of the synagogue was loosely followed. A completer organization was retarded by two factors, the presence of the apostles and the inspiration of the prophets. But when the apostles died and the early enthusiasm disappeared, a stricter order arose. Practical difficulties called for the enforcement of discipline, and differences of opinion for authority in doctrine; and, finally, the sacramentarian system required a priesthood. In the 2nd century the conception of a Catholic Church was widely held and a loose embodiment was given it; after the conversion of the empire the organization took on the official forms of the empire. Later it was modified by the rise of the feudal system and the re-establishment of the modern European nationalities.

The polity of the Church was more than a formal organization; it touched the life of each believer. Very early, Christianity was conceived to be a new system of law, and faith was interpreted as obedience. Legalism was joined with sacramentarianism, doubling the power of the priest. Through him Church discipline was administered, a complete system of ecclesiastical penalties, *i.e.*, penance, growing up. It culminated in the doctrine of purgatory, a place of discipline, of purifying suffering after death. The Roman genius for law strengthened and systematized this tendency.

The Roman Church.—The hierarchy which centres in the pope constitutes the Church of which the sacramental system is the inner life and penance is the sanction. It is thus a divine-human organization. It teaches that the divine-human Son of God established it, and returning to heaven committed to the apostles, especially to St. Peter, his authority, which has descended in an unbroken line through the popes. This is the charter of the Church, and its acceptance is the first requisite for salvation; for the Church determines doctrine, exercises discipline and administers sacraments. Its authority is accompanied by the spirit of God, who guides it into truth and gives it miraculous power. Outside the Church are only the "broken lights" of man's philosophy and the vain efforts of weak human nature after virtue.

Christianity in its complete Roman development is thus the coming of the supernatural into the natural. The universe falls into these orders, the second for the sake of the first, as nature is of and for God. Without Him nature at its highest is like a beautiful statue, devoid of life; it is of secondary moment compared even to men, for while it passes away he continues for ever. Man is dependent, therefore, not upon nature, but upon God's grace for salvation, and this comes through the Church. Thus the Church ever receives God and has a twofold nature; its sacraments through material and earthly elements impart a divine power; its teachings agree with the highest truths of philosophy and science, yet add to these the knowledge of mysteries which the unaided reason of man could never apprehend. Theology is the queen of the sciences, and nothing should be taught in school or university which contradicts its conclusions. Moreover, nothing should be done by the State which interferes with the transcendent interest committed to the Church. Thus the Church touches and controls all realms of life, and the cycle is complete.

The Reformation.—The idea of the Roman Church was imperfectly embodied at the best; the divine gift was in earthen vessels. The world was never completely cast out; indeed the Church became the scene for ambition and the home of luxury

and pleasure. It was entangled also in the political strife of the feudal ages and of the beginning of modern empires. Its control of the sciences embroiled it with its own philosophers and scholars, while saints and pure-minded ecclesiastics attempted, without success, its reform from within. Finally, through Luther, the explosion came, and western Christendom broke into two parts—Catholic and Protestant.

Protestantism in its primary principle is the return to primitive Christianity. The whole development which we have traced, culminating in the ecclesiastical-doctrinal system of the Roman Church, is regarded as a corruption, since foreign and even heathen elements have been brought in, so that the religion established by Christ is obscured or lost. For Protestants the Bible only now becomes the infallible inspired authority in faith and morals. Interpretations by the Fathers or by the councils are to be taken only as aids to its understanding. But in Protestantism reason and the light of nature are in themselves as impotent as in the Roman Church. The Bible interpreted by man's unaided intelligence is as valueless as other writings, but it has a sacramental value when the Holy Spirit accompanies its teaching, and the power of God uses it and makes the soul capable of holiness. In all this the supernatural is as vividly realized as in the Roman Church; it is only its mediation which is different.

These principles are variously worked out in the different churches and variously expressed. In part because of historical circumstances, the divergence from the older systems is more marked in some Protestant churches than in others, yet on the whole these two principles determine cult and in part organization. As in the Roman Church cult centres in the mass, so in the original Reformed Church it centred in the sermon. The ancient Jewish prophetic office was revived, yet with a difference: the ancient prophets acknowledged no external authority, but the Protestant preacher is strictly subordinate to the Scriptures of which he is the interpreter. Besides the sermon, the sacraments are observed as established by Christ—two in number, baptism and the Lord's Supper. But these do not exert a quasi-physical or magical influence, *ex opere operato*. Unless there be faith in the recipient, an understanding of the meaning of the sacrament and an acceptance of it, it is valueless or harmful. Prayer and praise also are effective only as the congregation intelligently joins in them.

The emphasis upon the believer and his freedom from all external authority do not result in a thoroughgoing individualism. Luther clearly held to the unity of all Christians, and Protestants are agreed in this. For them, as for the Roman Church, there is a belief in a catholic or all-embracing Church, but the unity is not that of an organization; Christians are one through an indwelling spirit; they undergo the same experience and follow the same purpose.

Historically these principles were only in part embodied, for the Reformation was involved in political strife. The Reformers turned to the Government for aid and protection, and throughout Europe turmoil and war ensued. In consequence, in the Protestant nations the State assumed the ultimate authority over the Church. Moreover, in the early days of the Reformation the Catholic Church charged it with a lawless individualism, a charge which was seemingly made good by an extreme divergence in theological opinion and by riots in various part of the Protestant world. The age was indeed one of ferment, so that the foundations of society and of religion seemed threatened. The Reformers turned to the State for protection against the Roman Church, and ultimately as a refuge from anarchy, and they also returned to the theology of the Fathers as their safeguard against heresy. Instead of the simplicity of Luther's earlier writings, a dogmatic theology was formed, and a Protestant ecclesiasticism established, indistinguishable from the Roman Church in principle. The main difference was in the attitude to the Roman allegiance and to the sacramentarian system. There was thus by no means a complete return to the Bible as the sole authority, but the Bible was taken as interpreted by the earlier creeds and as worked into a doctrinal system by the scholastic philosophy. Thus Protestantism also came to identify theology with the whole range of human knowledge, and in its official forms was as hostile to the progress

of science as was the Roman Church itself.

Many Protestants rebelled against this radical departure from the principles of the Reformation and of biblical Christianity. To them it seems the substitution of the authority of the Church for the authority of a living experience, and of intellectual adherence to theological propositions for faith. The freedom of the individual was denied. Protestantism divided into many sects and denominations, founded upon special types of religious experience or upon particular points in doctrine or in cult. Thus Protestantism presents a wide diversity in comparison with the regularity of the Roman Church (*see* REUNION).

Christianity and the Modern World.—The coming of the northern peoples into the Roman world profoundly modified Christianity. It shared indeed in the dreariness and corruption of the times commonly called the "dark ages," but when at last a productive period began the Church was the first to profit by it. Since all educated men were priests, it assimilated the new learning—the revived Aristotelianism—and continued its control of the universities. In the 13th century it was supreme, and Christianity was identified with world systems of knowledge and politics. Both were deemed alike divine in origin, and to question their validity was an offence against God. Christianity thus had passed through three stages in politics as in science. At first it was persecuted by the State, then established by it, and finally dominated over it; so its teaching was at first alien to philosophy and despised by it, next was accepted by it and given form and rights through it, and finally became queen of the sciences as theology and ruled over the whole world of human knowledge. But the triumph by its completeness ensured new conflicts; from the disorder of the middle ages arose states which ultimately asserted complete autonomy, and in like fashion new intellectual powers came forth which ultimately established the independence of the sciences.

In the broadest sense the underlying principle of the struggle is the reassertion of interest in the world. It is no longer merely the scene for the drama of the soul and God, nor is man independent of it, but man and nature constitute an organism, humanity being a part of the vaster whole. Man's place is not even central, as he appears a temporary inhabitant of a minor planet in one of the lesser stellar systems. As in the political world the States gained first the undisputed control of matters secular, rejecting even the proffered counsel of the Church, and then proceeded to establish their sovereignty over the Church itself, so was it in the empire of the mind. The rights gained for independent research were extended over the realm of religion also; the two indeed cannot remain separate, and man must subordinate knowledge to the authority of religion—or make science supreme, submitting religion to its scrutiny and judging it like other phenomena. Under this investigation Christianity does not appear altogether exceptional. Its early logic, ontology, and cosmology, with many of its distinctive doctrines, are shown to be the natural offspring of the races and ages which gave them birth. Put into their historical environment they are found to be steps in the intellectual development of man's mind. But when put forward as absolute truths to-day, they are put aside as anachronisms not worthy of dispute. The Bible is studied like other works, its origins discovered and its place in comparative religion assigned. It does not appear as altogether unique, but it is put among the other sacred books. For the great religions of the world show similar cycles of development, similar appropriations of prevalent science and philosophy, similar conservative insistence upon ancient truth, and similar claims to an exclusive authority.

With this interest is involved an attitude of mind toward the supernatural. As already pointed out, nature and super-nature were taken as physically and spatially distinct. The latter could descend upon the former and be imparted to it, neither subject to nature nor intelligible by reason. In science the process has been reversed; nature ascends, so to speak, into the region of the supernatural and subdues it to itself; the marvellous or miraculous is brought under the domain of natural law, the canons of physics extend over metaphysics, and religion takes its place as one element in the natural relationship of man to his environment. Hence the new world-view threatens the foundations of the ecclesiastical

edifice. This revolution in the world-view is no longer the possession of philosophers and scholars, but the multitude accepts it in part. Education in general has rendered many familiar with the teachings of science, and, moreover, its practical benefits have given authority to its maxims and theories.

The *Roman Catholic Church* uncompromisingly reasserts its ancient propositions, political and theological. The cause is lost indeed in the political realm, where the Church is obliged to submit, but it protests and does not waive or modify its claims (*see the Syllabus* of 1864, par. 19 *seq.*, 27, 54 and 55). In the Greek and Protestant churches this situation cannot arise, as they make no claims to governmental sovereignty. In the intellectual domain the situation is more complex. Again the Roman Church unhesitatingly reaffirms the ancient principles in their extreme form (*Syllabus*, par. 8–9–13; *Decrees of the Vatican Council*, ch. 4, especially canon 4–2); the works of St. Thomas Aquinas are recommended as the standard authority in theology (*Encyc. of Leo XIII., Aeterni Patris*, Aug. 4, 1879). In details also the conclusions of modern science are rejected, as for example the origin of man from lower species, and, in a different sphere, the conclusions of experts as to the origins of the Bible. Faith is defined as "assent upon authority," and the authority is the Church, which maintains its right to supremacy over the whole domain of science and philosophy.

The *Greek Church* remains untouched by the modern spirit. With characteristic oriental conservatism it claims the title of "Orthodox" and retains the creed and organization of the early Church. The *Protestant Churches* also are bound officially to the scholastic philosophy of the 17th century; their confessions of faith still assert the formation of the world in six days, and require assent to propositions which can be true only if the old cosmology be correct.

Compromises.—On the other hand there are individuals and even large bodies of Christians who are intent upon a reinterpretation. Even in the official circles of the Church, not excepting the Roman Church, there are many scholars who find no difficulty in maintaining communion while accepting the modern scientific view of the world. This is possible to some because the situation in its sharp antithesis is not present to their minds: by making certain compromises on the one side and on the other, and by framing private interpretations of important dogmas, they can retain their faith in both and yet preserve their mental integrity.

Thus the crisis is in fact not so acute as it might seem. No great institution lives or dies by logic. Christianity rests on great religious needs which it meets and gratifies, so that its life (like all other lives) is in unrationalized emotions. Reason seeks ever to rationalize these, an attempt which seems to destroy yet really fulfils. As thus the restless reason tests the emotions of the soul criticizes the traditions to which they cling, rejects the ancient dogmas in which they have been defined, the Church slowly participates in the process; silently this position and that are forsaken, legends and beliefs once of prime importance are forgotten, or when forced into controversy many ways are found by which the old and the new are reconciled; the sharpness of distinctions can be rubbed off, expressions may be softened, definitions can be modified and half-way resting-places afforded until the momentous transition has been made and the continuity of tradition is maintained. Finally, as the last step, even the official documents may be revised.

Philosophy and Ethical Redemption.—The intellectual crisis cannot be ignored in the interest of the practical life. Men must rationalize the universe. On the one hand there are church men who attempt to repeat the historical process which has naturalized the Church in alien soils by appropriating the forces of the new environment, and who hold that the entire process is inspired and guided by the spirit of God. Hence Christianity is the absolute religion, because it does not preclude development but necessitates it, so that the Christianity that is to come shall not only retain all that is important in the Christianity of the past and present but shall assimilate new truth. On the other hand some seek the essential Christianity in a life beneath and separable from the historic forms. In part under the influence of the Hegelian

philosophy, and in part because of the prevalent evolutionary scientific world-view, God is represented under the form of pure thought, and the world process as the unfolding of Himself. Such truth can be apprehended by the multitude only in symbols which guide the will through the imagination, and through historic facts which are embodiment of ideas. The Trinity is the essential Christian doctrine, the historic facts of the Christian religion being the embodiment of religious ideas. The chief critical difficulty felt by this school is in identifying any concrete historic fact with the unchanging idea, that is, in making Jesus of Nazareth the incarnation of God. God is reinterpreted, and in place of an extra-mundane creator is an omnipresent life and power. The Christian attainment is nothing else than the thorough intellectual grasp of the absolute idea and the identification of our essential selves with God. With a less thoroughgoing intellectualism other scholars re-interpret Christianity in terms of current scientific phraseology. Christianity is dependent upon the understanding of the universe; hence it is the duty of believers to put it into the new setting, so that it adopts and adapts astronomy, geology, biology and psychology.

From all these efforts to reconstruct systematic theology with its appropriations of philosophy and science, groups of Christians turn to the inner life and seek in its realities to find the confirmation of their faith. They also claim oneness with a long line of Christians, for in every age there have been men who have ignored the dogma and the ritual of the Church, and in contemplation and retirement have sought to know God immediately in their own experience. To them at best theology with its cosmology and its logic is only a shadow of shadows, for God reveals himself to the pure in heart, and it matters not what science may say of the material and fleeting world. This spirit manifests itself in wide circles in our day. The Gordian knot is cut, for philosophy and religion no longer touch each other but abide in separate realms.

In quite a different way a still more influential school seeks essential Christianity in the sphere of the ethical life. It also would disentangle religion from cosmology and formal philosophy. It studies the historic development of the Church, noting how element after element has been introduced into the simplicity of the gospel, and from all these it would turn back to the Bible itself. In a thoroughgoing fashion it would accomplish what Luther and the Reformation attempted. It regards even the earliest creeds as only more or less satisfactory attempts to translate the Christian facts into the current language of the heathen world. But the process does not stop with this rejection of the ancient and the scholastic theology. It recognizes the scientific results attained in the study of the Bible itself, and therefore it does not seek the entire Bible as its rule of truth. To it Jesus Christ, and He alone, is supreme, but this supremacy does not carry with it infallibility in the realm of cosmology or of history. In these too Jesus participated in the views of His own time; even His teaching of God and of the future life is not lacking in Jewish elements, yet none the less He is the essential element in Christianity, and to His life-purpose must all that claims to be Christianity be brought to be judged. To this school Christianity is the culmination of the ethical monotheism of the Old Testament, which finds its highest ideal in self-sacrificing love. Jesus Christ is the complete embodiment of this ideal, in life and in death. This ideal He sets before men under the traditional forms of the Kingdom of God as the object to be attained, a Kingdom which takes upon itself the forms of the family, and realizes itself in a new relationship of universal brotherhood. Such a religion appeals for its self-verification not to its agreement with cosmological conceptions, either ancient or modern, or with theories of philosophy, however true these may be, but to the moral sense of man. On the one hand, in its ethical development, it is nothing less than the outworking of that principle of Jesus Christ which led Him not only to self-sacrificing labour but to the death upon the cross. On the other hand, it finds its religious solution in the trust in a power not ourselves which makes for the same righteousness which was incarnate in Jesus Christ.

Thus Christianity, as religion, is on the one hand the adoration of God, that is, of the highest and noblest, and this highest and

noblest as conceived not under forms of power or knowledge but in the form of ethical self-devotion as embodied in Jesus Christ, and on the other hand it meets the requirements of all religion in its dependence, not indeed upon some absolute idea or omnipotent power, but in the belief that that which appeals to the soul as worthy of supreme worship is also that in which the soul may trust, and which shall deliver it from sin and fear and death. Such a conception of Christianity can recognize many embodiments in ritual, organization and dogma, but its test in all ages and in all lands is conformity to the purpose of the life of Christ. The Lord's Prayer in its oldest and simplest form is the expression of its faith, and Christ's separation of mankind on the right hand and on the left in accordance with their service or refusal of service to their fellow-men is its own judgment of the right of any age or Church to the name Christian.

Christianity has passed through too many changes, and it has found too many interpretations possible, to fear the time to come. Thoroughgoing reconstruction in every item of theology and in every detail of polity there may be, yet shall the Christian life go on—the life which finds its deepest utterance in the words of Christ, "Thou shalt love the Lord thy God with all thy heart and thy neighbour as thyself"; the life which expresses its profoundest faith in the words Christ taught it to pray, "Our Father"; the life which finds its highest rule of conduct in the words of its first and greatest interpreter, "Let this mind be in you which was also in Christ Jesus our Lord."

The view that Jesus deliberately founded a Church (an ecclesiastical institution), appointed the Apostles its rulers, settled its rites, gave it its doctrine and guaranteed its fidelity, can only be maintained by discarding history altogether. In the 19th century this was transformed into the view that Jesus planted "in germ" what has grown to be the present Catholic doctrine and order. Among those who differ only in detail about what happened, there are, however, diametrically opposite judgments of the value of the change. (i.) Liberal Protestant scholars, on the whole, regard it as the kind of corruption to which religions are always subject as they absorb alien elements with their imperfectly instructed converts. They find the essential Christian element to be a power, shown by no other religion, first of elevating and spiritualizing these alien elements and then of eliminating them. This they ascribe to the higher idea of redemption inseparable from the faith in Christ (which, however much overlaid, has always wrought like leaven), and to what goes with it—the Revelation of the Father. Thus, for them, an essential quality of Christianity is its power to regenerate itself by a return to the Jesus of the Gospels. They would maintain that all other religions have their place, but it is as a preparation, or if their elements remain in Christianity, it is only as a temporary substitute for the true Christian redemption. (ii.) Liberal Catholic scholars on the other hand regard it as the highest perfection of Christianity that it can thus "syncretize" (absorb and transform) what has appealed to human need in any religion. By this comprehensiveness, they maintain, Christianity, from being an enthusiastic but incoherent movement, grew into a permanent and effective institution, with its original puritanism enriched in all kinds of religiously valuable ways.

The foregoing statement is a definition not of two positions but of two *directions*, and allows for various intermediate doctrines and interpretations. All these are naturally exemplified in the principal branches of organized Christianity, and reference must be made to the various articles on these subjects: ROMAN CATHOLIC CHURCH; ENGLAND, CHURCH OF; PRESBYTERIANISM; LUTHERANISM; CONGREGATIONALISM; METHODISM; etc.

BIBLIOGRAPHY.—On such a vast subject we can here refer to only a few of those books which give guidance for further study and are typical of each of its main lines. For Roman Catholicism: P. Batiffol, *L'Église naissante et le catholicisme* (4th ed., 1909); Wilhelm and Scannell, *Manual of Catholic Theology* (1899); C. S. Devas, *The Key to the World's Progress* (1906); and many articles in the *Catholic Encyclopaedia*. For Anglicanism: *Lux Mundi* (1890); Gore, *Orders and Unity* (1909); *The Reconstruction of Belief* (1927); Darwell Stone, *The Church, its Ministry and Authority* (1902); A. C. Headlam (Bishop of Gloucester), *The Church of England* (1927). For the Free Churches: *Towards Reunion*, by Church of England and Free Church writers (1919); G. K. A. Bell, *Documents on Christian Unity*

(1924); G. K. A. Bell and W. Robertson (ed. by), *The Church of England and the Free Churches* (1925); A. E. Garvie, art. "Christianity" in Hastings' *Encyclopaedia of Religion and Ethics* (for liberal Evangelicalism); J. E. Carpenter (ed. by), *Freedom and Truth* (1925), for Unitarian Christianity (see also James Drummond, *Via, Veritas, Vita or Christianity in its simplest and most intelligible form*; Hibbert Lectures, 1894; and Charles Beard, *The Reformation in its Relation to Modern Thought and Knowledge*: Hibbert Lectures, 1883).

For the principles of Protestantism as a Religion: A. Ritschl, *Christian Doctrine of Justification and Reconciliation* (Eng. trans., 1900), most important for its present influence (for a critical estimate, Garvie, *The Ritschlian Theology*, 1897); E. Troeltsch, *Die Absolutheit des Christentums* (1902); W. Hermann, *Communion of the Christian with God* (Eng. trans., 1895), a discussion in the spirit of Luther; A. Sabatier, *Religions of Authority and the Religion of the Spirit* (Eng. trans., 1904). On primitive Christianity, see Harnack, *Mission and Expansion of Christianity in the first three centuries* (Eng. trans., 1904); Wernle, *Beginnings of Christianity* (Eng. trans., 1904); Weizsacker, *The Apostolic Age* (Eng. trans., 1897); Hatch, *Influence of Greek Ideas and Usages on the Christian Church* (Hibbert Lectures, 1888). (G. W. KN.; S. H. M.)

CHRISTIAN OF BRUNSWICK (1599-1626), bishop of Halberstadt, a younger son of Henry Julius, duke of Brunswick-Wolfenbüttel, was born in Gröningen on Sept. 20, 1599. Having succeeded his father as "bishop" of Halberstadt in 1616, he obtained some experience of warfare under Maurice, prince of Orange, in the Netherlands. Raising an army he entered the service of Frederick V., elector palatine of the Rhine, and attacked the lands of the elector of Mainz and the bishops of Westphalia. After some successes he was defeated by Tilly at Höchst in June 1622; then, dismissed from Frederick's service, he entered that of the United Provinces, losing an arm at the battle of Fleurus. In 1623 he was beaten by Tilly at Stadtlohn and driven back to the Netherlands. When in 1625 Christian IV., king of Denmark, entered the arena of the war, he took the field again in the Protestant interest, but after some successes he died at Wolfenbüttel on June 16, 1626. (See also THIRTY YEARS WAR.)

CHRISTIANSAND, a fortified seaport of Norway, the chief town of the diocese (*stift*) of Agder on a fjord of the Skagerrack, 175 m. S.W. of Oslo (Christiania). Pop. (1920) 16,543. It stands on a square peninsula flanked by the western and eastern harbours and by the Otter river, among wooded hills and islands. It is a fishing centre (salmon, mackerel, lobsters), with saw-mills, wood-pulp factories, shipbuilding yards and mechanical workshops. The port is the largest on the south coast; coast and foreign steamers on the way to Christiania touch here. The Saetersdal railway follows that valley north to Byglandsfjord (48 m.), whence a good road continues to Viken i Valle at the head of the valley. Flekkerø, a neighbouring island, is a favourite pleasure resort. The town was founded in 1641 by Christian IV.

CHRISTIAN SCIENCE, the religion founded by Mary Baker Eddy; the religion represented by the Church of Christ, Scientist. Applicable to health, as the Christian religion originally was, Christian Science is a religious teaching and practice based on the words and works of Christ Jesus. As defined by Mrs. Eddy, it is "divine metaphysics"; it is "the scientific system of divine healing"; it is "the law of God, the law of good, interpreting and demonstrating the divine Principle and rule of universal harmony" (*Science and Health with Key to the Scriptures*, p. 111, 123; *Rudimental Divine Science*, p. 1). For many years prior to 1866 Mrs. Eddy had observed and studied mental causes and effects. Profoundly religious, she was disposed to attribute causation to God and to regard Him as divine Mind. At Lynn, Mass., in that year, she recovered almost instantly from a severe injury after reading an account of healing in the Gospel according to St. Matthew ix, 1-8. The discovery of what she named Christian Science ensued from this incident. As she has said, "I knew the Principle of all harmonious Mind-action to be God, and that cures were produced in primitive Christian healing by holy, uplifting faith; but I must know the Science of this healing, and I won my way to absolute conclusions through divine revelation, reason and demonstration" (*Science and Health*, p. 109).

At Boston, in 1875, Mrs. Eddy published her principal work,

first called *Science and Health* but afterward entitled *Science and Health with Key to the Scriptures*. It is known also as the Christian Science text-book. Occasionally revised by the author, "only to be a clearer and fuller expression of its original meaning" (p. 361), this book received from her its final revision in 1907. It is read in Christian Science services in connection with the Bible, and is to be found in all Christian Science reading rooms as well as in public libraries. For other works on Christian Science by Mrs. Eddy, see the bibliography under EDDY, MARY BAKER. Mrs. Eddy also attached great importance to periodical literature. She founded the *Christian Science Journal* (a monthly in English) in 1883, and the *Christian Science Quarterly* (containing the lesson-sermons for Sunday services) in 1890. It is published in English, Danish, Dutch, French, German, Norwegian, Swedish and in revised Braille. She founded the *Christian Science Sentinel* (a weekly in English) in 1898; *Der Herold der Christian Science* (a monthly in German) in 1903; and the *Christian Science Monitor* (an international daily newspaper) in 1908. *Le Heraut de Christian Science* (a monthly in French) dates from 1918. All except one of these periodicals circulate chiefly among people who have some degree of interest in Christian Science, but the *Christian Science Monitor* has become established as an excellent newspaper in the estimation of many people who are entirely indifferent towards the religion which it promotes but does not obtrude or even stress.

At first, Mrs. Eddy did not expect to found a distinct church or denomination; she hoped that her discovery would be accepted soon by existing churches. In a short time, however, a distinct church became needed to facilitate co-operation and unity between Christian Scientists, to present Christian Science to other people and to maintain the purity of its teaching and practice. Accordingly, at Boston, in 1879, Mrs. Eddy with her followers founded the Church of Christ, Scientist. Soon the original organization became inadequate for the growing denomination. To the first congregation in Boston there were added numbers of Christian Scientists at other places. Local churches as well as a central organization or Mother Church became necessary. Therefore, in 1892, Mrs. Eddy with her followers founded the Christian Science Mother Church, The First Church of Christ, Scientist, in Boston of which the local churches throughout the world are regarded as branches.

Mrs. Eddy passed away in 1910. Until then she had initiated every step in the progress of Christian Science. Nothing of moment was done without her approval. Furthermore, although the organic law of the Christian Science movement, its *Church Manual*, confers extensive and sufficient powers upon an administrative board, the Christian Science board of directors, yet this board always had functioned under her immediate supervision. Mrs. Eddy's demise, therefore, immediately tested the adequacy of the *Church Manual* as an organic law and the loyalty of Christian Scientists to this law, in the absence of its author. Nevertheless the period since 1910 has been the most fruitful and prosperous in the history of Christian Science.

The theology of Christian Science begins with the proposition that God is the only might or Mind; that He is "the divine Principle of all that really is" (*Science and Health*, p. 275). To define God further, it employs frequently the word Good, besides such terms as Life, Truth, Love, Soul, Spirit and Infinite Person. Next to God, the name Jesus and references to Him occur most frequently in the authorized literature of Christian Science. Concerning Jesus the Christ and His relation to God and men, Christian Science distinguishes between what is in the New Testament and what is in the creeds, doctrines and dogmas of later times. Accordingly, Christian Scientists speak of Him oftenest as the Way or Way-shower and they regard His atonement, His chief work, as "the exemplification of man's unity with God, whereby man reflects divine Truth, Life and Love" (*Science and Health* p. 18).

The most distinctive feature of Christian Science teaching is its absolute distinction between what is real and what is apparent or seeming but unreal. This distinction Mrs. Eddy explains, for instance, as follows: "All reality is in God and His creation, har-

monious and eternal. That which He creates is good, and He makes all that is made. Therefore the only reality of sin, sickness or death is the awful fact that unrealities seem real to human, erring belief, until God strips off their disguise. They are not true, because they are not of God" (*Science and Health*, p. 472). Contrary to common misapprehension, Christian Science does not ignore what it regards as unreal. This religion teaches its adherents to forsake and overcome every form of error or evil on the basis of its unreality; that is, by demonstrating the true idea of reality. This it teaches them to do by means of spiritual understanding, spiritual law and spiritual power.

In this connection, Christian Science maintains that the truth of being, the truth concerning God and man, includes a rule for its practice and a law by which its practice produces effects. To a certain extent Jesus declared this rule and law when he said, "Ye shall know the truth, and the truth shall make you free" (John viii. 32). Accordingly, for an individual to gain his freedom from any form of error or evil, he should know the truth, the absolute truth of being, applicable to his case; and Christian Science further teaches that this practice is effective when employed by one individual for another, because such is the unity of real being and such is the law of God. For these reasons, evidently Jesus could and did declare the possibility of Christian healing in unlimited terms. See Matthew x. 5-10 and xxviii. 16-20; Mark xvi. 14-18; John xiv. 12.

The practice of Christian Science is not merely mental; it must be also spiritual. Indeed, it is truly mental only as it is absolutely spiritual. The non-spiritual elements in the so-called human mind do not contribute to harmony or health. The practitioner must know or realize spiritually, and his ability to do this is derived from the divine Mind. Therefore, he must agree with the Teacher and Way-shower who said, "I can of mine own self do nothing" (John v. 30), and must prepare for the healing ministry and keep himself in condition for it by living the life of a genuine Christian. The practice of Christian Science is not limited, as is commonly supposed, to the healing of the sick. On the contrary, Christian Scientists regard their religion as applicable practically to every human need.

While the adherents of Christian Science are chiefly found among people who read English, it has followers among Christian people everywhere and also among Jews. In 1928 there were 2,351 churches, besides many groups not yet formally organized. Of these churches, there were in the United States 1,983; in Great Britain, 186; Germany, 47; other countries, 147. (C. P. S.)

CHRISTIAN SOCIALISM. In English history, the name given to the doctrines of F. Denison Maurice, J. R. Ludlow, E. Vansittart Neale, Charles Kingsley, Thomas Hughes (*qq.v.*) and several others who entered on public propaganda immediately after the failure of the great Chartist demonstration of April 10, 1848 (see **CHARTISM**). These writers produced a journal named *Politics for the People* in 1848 (in which Kingsley wrote the famous phrase about religion being "an opium dose for . . . the people" now on the walls of the Kremlin in Moscow), *Tracts for Christian Socialists* (1850), *The Christian Socialist* (1850) and *The Journal of Association* (1852), all of which had a small circulation and died an early death.

Industrially, their chief work was a revival of the co-operative movement and to set going small self-governing workshops, none of which were able to survive. They also founded a "wholesale agency" which is a precursor of the Co-operative Wholesale Society, and signally aided in securing the enactment of the Industrial and Provident Societies Act of 1852, which made possible the growth of the modern co-operative movement.

Later Developments. Though the Christian Socialists had

never had many adherents and their movement appeared to have ended in failure, their influence was carried on till the Socialist revival of the end of the century, when it inspired the Guild of St. Matthew, founded in 1877 by the late Stewart Headlam and claiming to be the oldest Socialist body in Britain. At the beginning of the next century a number of small propagandist bodies, of which the most active was the Church Socialist League, were able to record great successes in appealing to the Churches; and certain of their members entertained a hope of an approaching conversion of the Churches to Socialism. The Pan-Anglican Congress of 1908 attacked social conditions in vigorous terms: the Lambeth Conference of the same year, attended by 242 bishops and archbishops, pronounced a similar verdict and approved the 1907 report of a Committee of Convocation which had endorsed the views of those "deep-seeing men, Carlyle, Maurice and Ruskin." Bishop Gore, in the Church Congress sermon of 1906, had summarized the aims of the revived movement: "The question which ought to hold a pre-eminent place in the interests of Churchmen is, how we are to return to a condition of things nearer to the intention of Christ—if it may be, without violence or revolution; but if not, then anyhow to return." But these hopes were frustrated: the enthusiasm of 1908 had but a passing effect on the hierarchy, most of which remained hostile to Socialism, while after the War the Church Socialist League itself was rent by dissension. The C.S.L. passed out of existence in 1923 (becoming the "League of the Kingdom of God"), it being held by a majority of the members that the Church must have its own social programme, and could not adopt a Socialism from outside or ally itself with any particular Party. There are indeed many Christian social reform bodies, some of wide influence, of which the chief is "Copec" a central unifying body founded at a great interdenominational conference at Birmingham in 1924, but they are not specifically Socialist.

On the continent of Europe "Christian Socialist" is used in a wholly different sense to denote parties or trade unions directed by religious leaders as rivals to the Socialist unions or parties and with the object of weakening their influence.

See Conrad Noel, *Socialism in Church History* (1910); C. Raven, *Christian Socialism* (1921). (R. W. P.)

CHRISTIANSUND, a seaport on the west coast of Norway, in Romsdal amt (county), 259 m. N.E. by N. of Bergen, in the latitude of the Faeroe Islands. Pop. (1920) 15,181. It is built on four small islands, by which its harbour is enclosed. The chief exports are wood, cod, herrings and fish products, and butter to Great Britain. The town is the chief port of the district of Nordmøre. Local steamers serve the neighbouring fjords, including the Sundalsfjord, from which at Sundalsören a driving road past the fine Dovrefjeld connects with the Gudbrandsdal route. Till 1742, when it received town privileges from Christian VI. Christiansund was called Lille-Fosen.

CHRISTIAN UNITY, a term used in America for the reunion of churches of different denominations. In other countries the movement is known as Church Reunion. (See **REUNION, CHURCH**.)

The first pronounced appeal for Christian unity in the United States came from Barton W. Stone, a Presbyterian minister of Kentucky, in 1804, and from Thomas Campbell and his son, Alexander, of the Seceder Presbyterian Church in western Pennsylvania, in 1809. Unfortunately the activities of these leaders crystallized into two denominations. Stone and the Campbells were regarded as the leaders in the denomination that came to be known as the Disciples of Christ, and those who did not follow Stone in his union with the Campbells formed a denomination that came to be known as the Christians. The controversies of those periods, in the midst of other interests, quite obscured the message of these movements for Christian unity. Perhaps the times were not ripe for the work of these pioneers. From the middle of the 19th century to nearly its close Philip Schaff, of the Reformed Church, was, perhaps, the foremost voice for Christian unity in the United States. He was one of the founders of the American branch of the Evangelical Alliance.

The extension of the Young Men's Christian Association from

England into the United States in 1844 and the combining of several organizations in England in 1884 into the Young Women's Christian Association, which soon extended to the United States, brought together the leaders of the various Protestant denominations and indirectly contributed to an awakening of interest in Christian unity. The rise of the Christian Endeavor movement in 1881, under the leadership of Francis E. Clark, a Congregational minister of Portland, Maine, brought together the young people of all Protestant denominations except those denominations (Baptist, Methodist, Presbyterian and Lutheran) that pulled away, organizing their young people denominationally. The Christian Endeavor movement, therefore, made possible a generation of young people with new approaches to those of other denominations and opened the way to subsequent adventures toward unity. The Federal Council of the Churches of Christ in America, composed of 30 Protestant denominations, was organized in 1908 in Philadelphia for the co-operation of the various Protestant denominations in service rather than an attempt to unite upon definitions of theology and polity. Its headquarters are located in New York city. Aside from the general service through these denominations, more than 50 municipalities and, likewise, several States, have formed church federations.

The more direct approach to Christian unity in the United States centres around the year 1910. In the summer of that year several Protestant Episcopalians organized the Christian Unity Foundation of New York for the promotion of Christian unity throughout the world by research and conference. They invited representatives of several denominations to be their guests for conference, and published pamphlets announcing the results of these conferences. It was the first attempt on the part of one denomination to set forth under its own authorship and at its own expense a friendly interpretation of another denomination without some adverse criticism.

On Oct. 19 of that same year, at the General Convention of the Protestant Episcopal Church, meeting in Cincinnati, a commission, consisting of seven bishops, seven presbyters, and seven laymen, was appointed to take under advisement the promotion of a world conference on the faith and order of the Church to be participated in by representatives of all Christian bodies throughout the world. On the same day the Disciples of Christ, meeting in their General Convention in Topeka, organized an Association for the Promotion of Christian Unity, emphasizing intercessory prayer, friendly conferences and the distribution of Christian unity literature by writers from all denominations. At the same time the Congregationalists, meeting in their National Council in Boston, appointed a commission on Christian unity, dealing with all churches, but especially with the Protestant Episcopal Church.

The Episcopal movement, under the leadership of Robert H. Gardiner, soon brought into co-operation representatives from most of the Christian denominations, and the first preliminary world conference on faith and order, held at Geneva, Switzerland, in 1920, marked the opening of a new chapter in theological reconciliation. The World Conference, after 17 years' preparation, was held August 3 to 21, 1927, at Lausanne. Of the larger churches only the Roman Catholic Church declined the invitation, but the pope expressed sympathetic interest. For nearly three weeks representatives from the Eastern Orthodox, Anglican and Protestant churches, sat together in friendly conference over such questions as "The Call to Unity," "The Church's Message to the World—the Gospel," "The Nature of the Church," "The Church's Common Confession of Faith," "The Church's Ministry," "The Sacraments," and "The Unity of Christendom and the Relation Thereto of Existing Churches." Their findings were sent to all the participating churches. The headquarters of the World Conference on Faith and Order are in Boston, Mass.

The Disciple movement continued its policy as announced by its Association for the Promotion of Christian Unity for some years and then adopted a rather denominational attitude, confining its work largely to its own denomination. However, out of it came *The Christian Union Quarterly*, which W. H. Hoover, North Canton, Ohio, endowed sufficiently to make it independent of any denomination and to function inter-denominationally, with an

inter-denominational editorial council composed of representatives from various denominations in all parts of the world. The Congregational movement functioned in a general agitation for Christian unity, particularly under the leadership of Newman Smyth, who advocated a concordat with the Protestant Episcopal Church. This, however, failed of ratification by either denomination. At the instance of the Presbyterian General Assembly in 1918 the American Council on Organic Union of the Evangelical Churches of America was organized and bore testimony to the necessity of Christian unity by a representative gathering in Philadelphia, in which 16 Protestant denominations took part. Nothing definite came out of this movement.

In May 1927, the Christian Unity League was launched in Baltimore, Md., as an organization to include the study of all Christian unity movements and at the same time to make adventures beyond present day practices. They held a conference at the First Presbyterian Church, Baltimore, Jan. 12 and 13, 1928, with 25 denominations from 11 States and Canada. In their findings they advocated modern biblical interpretations in the historical study of the origin and valuation of Christian creeds and institutions, that representatives in foreign mission fields be given larger freedom as regards Christian unity and that steps be taken gradually to make all denominational schools and all denominational papers inter-denominational. The conference closed with all of the denominations taking part in the celebration of the Lord's Supper.

CHRISTIE, RICHARD COPLEY (1830–1901), English scholar and bibliophile, was born on July 22, 1830, at Lenton Nottinghamshire, the son of a millowner. He was educated at Lincoln college, Oxford, was called to the bar at Lincoln's Inn in 1857, and in 1872 became chancellor of the diocese of Manchester. This he resigned in 1893. He held numerous appointments notably the professorships of history (from 1854 to 1856) and of political economy (from 1855 to 1866) at Owens college, Manchester. He always took an active interest in this college, of which he was one of the governors; in 1893 he gave the Christie library building designed by Alfred Waterhouse, and in 1899 he devoted £50,000 of the funds at his disposal as a trustee of Sir Joseph Whitworth's estate for the building of Whitworth Hall, which completed the front quadrangle of the college. He was an enthusiastic book collector, and bequeathed to Owens college his library of about 75,000 vols., rich in a very complete set of books printed by Dolet, a wonderful series of Aldines and of vols. printed by Sebastian Gryphius. His *Étienne Dolet the Martyr of the Renaissance* (1880), is the most exhaustive work on the subject. He died at Ribsden on Jan. 9, 1901.

CHRISTIE, SIR WILLIAM HENRY MAHONEY (1845–1922), British astronomer, son of Samuel Hunter Christie professor of Mathematics at the royal military academy, Woolwich, was born at Woolwich on Oct. 1, 1845. He was educated at King's College school, London, and at Cambridge. In 1870 Christie was appointed chief assistant to Airy at the royal observatory Greenwich, and in 1881 astronomer royal; he retired from this post at the age of sixty-five.

While Christie was at the observatory the work was considerably extended, and it was largely due to him that regular spectroscopic and photographic observations were started. Some of these photographs form a valuable part of the work of the observatory, and the observations are still continued. Between 1890 and 1899 Christie supervised the construction of a new building and the erection of a 30 inch reflector and a 26 inch photographic refractor enabling the observatory to take part in the international photo

graphic map of the heavens; the measurements and publication of results occupied a number of years. Christie erected a wooden building for magnetic observations, designed a new altazimuth to replace a faulty one which had been used by Airy and also designed a "duplex" micrometer for identifying stars on overlapping plates.

Christie is the author of a number of papers embodying his work on the solar eclipses observed in Japan (1896), India (1898), and Portugal (1900), on the measurement of double stars, on the observations of Eros for determining the solar parallax and on the duration of exposure in photographing stars.

Christie was a member of many learned societies at home and abroad; he received the C.B. on the occasion of Queen Victoria's Jubilee and the K.C.B. in 1904. He died on Jan. 22, 1922 while on a voyage to Mogador and was buried at sea.

CHRISTINA (1626–1689), queen of Sweden, daughter of Gustavus Adolphus and Marie-Eleonore of Brandenburg, was born at Stockholm on Dec. 8, 1626. Her father was killed at Lützen (1632) when she was only six years old. She was educated principally by the learned Johannes Matthiae, in as masculine a way as possible, while the chancellor Oxenstjerna instructed her in politics. Christina became queen in her 18th year (Dec. 8, 1644). Her brilliant and commanding qualities were vitiated by an inordinate pride and egoism and a prodigality regardless of the necessities of the State. She maintained a luxurious court, frequented by French artists, scholars and philosophers; while her unworthy treatment of the great chancellor, Oxenstjerna, was mainly due to her jealousy of his reputation. Recognizing that he would be indispensable so long as the Thirty Years' War lasted, she used every effort to bring it to an end; and her impulsive interference seriously hampered the diplomacy of the chancellor, and materially reduced the ultimate gains of Sweden. Yet she gave fresh privileges to the towns; she encouraged trade and manufactures, especially the mining industries of the Dales; in 1649 she issued the first school ordinance for the whole kingdom; she encouraged foreign scholars to settle in Sweden; and native science and literature flourished under her encouragement. The senate and Estates, anxious about the succession to the throne, had repeatedly urged her to marry, and suggested her cousin, Charles Gustavus, as the most suitable consort. Wearied of their importunities Christina settled the difficulty by appointing Charles her successor, and at the *Riksdag* of 1650 the Swedish crown was declared hereditary in Charles and his heirs male. In the summer of 1651 Christina was with difficulty persuaded to reconsider her resolution to abdicate, but three years later the nation had become convinced that her abdication was highly desirable. Within ten years she had created 17 counts, 46 barons and 428 lesser nobles; and, to provide these new peers with adequate appanages, she had sold or mortgaged Crown property representing an annual income of 1,200,000 rix-dollars. She may also have been growing weary of the cares of government, while the importunity of the senate and *Riksdag* on the question of her marriage was a constant source of irritation, and the opportunity of astonishing the world by the unique spectacle of a great queen, in the prime of life, voluntarily resigning her crown, strongly appealed to her vivid imagination. From 1651 there was a notable change in her behaviour. She ostentatiously exhibited her contempt for the Protestant religion. Her foreign policy was flighty to the verge of foolishness. She contemplated an alliance with Spain, a state quite outside the orbit of Sweden's influence, the first-fruits of which were to have been an invasion of Portugal. She utterly neglected affairs in order to plunge into a whirl of dissipation with foreign favourites like Bourdelot. The situation became impossible. On June 6, 1654, Christina abdicated, in the presence of the Estates, at the castle of Uppsala, and it was with an intense feeling of relief that the Swedes saw her depart, in masculine attire, under the name of Count Dohna. At Innsbruck she openly joined the Catholic Church, was rechristened Alexandra and kept up a royal household in Rome, surrounded by cardinals. In 1656, and again in 1657, she visited France, on the second occasion ordering the assassination of her major-domo Monaldeschi for his continuous betrayal of her confidence. Twice she returned to Sweden (1660 and 1667)

in the vain hope of recovering the succession, finally settling in Rome, where she lived on the charity of the pope and died on April 19, 1689, poor, neglected and forgotten.

Bildt, *Christina de Suède et le conclave de Clement X.* (1906); *Drottning Kristinas sista dagar* (Stockholm, 1897). Of the many books telling the fantastic story of Christina's later years see A. Barine, *Princesses and Court Ladies* (Eng. trans., 1906); F. H. Gribble, *The Court of Christina of Sweden* (1913), and *The History of the Intrigues and Gallantries of Christina, Queen of Sweden, and of her Court whilst she was at Rome* (translated from the French by P. Hollingworth, 1697; repr. 1927).

CHRISTINA (MARIA CHRISTINA) (1858–1929), queen-regent of Spain (1885–1902), widow of Alphonso XII. and mother of Alphonso XIII., was born at Gross Seelowitz, in Austria, on July 21, 1858, being the daughter of the archduke Charles Ferdinand and the archduchess Elizabeth of Austria. In 1879 she married Alphonso XII. of Spain, whom she had met at the court of Vienna when he was only a pretender in exile, before the restoration of the Bourbons, and whose first wife, Mercedes, daughter of the duc de Montpensier, had died childless. Queen Christina bore her husband two daughters—Doña Mercedes, born on Sept. 11, 1880, and Doña Maria Theresa, born on Nov. 12, 1882. On her husband's death on Nov. 25, 1885, she became regent, and during the long minority of the posthumous son of Alphonso XII., afterwards Alphonso XIII., she exhibited her wisdom, tolerance and unselfishness. In spite of the excessive rotation of political parties under Sagasta and Canovas, the restlessness of the army, the economic depression and the disastrous war of 1898 with the United States, in which Spain renounced her rights over Cuba, Porto Rico and the Philippines, the country, under Christina, won the respect of the Great Powers, and opposition from the ex-royal family gradually diminished. Her regency ended in 1902, when Alphonso XIII. came of age. She died Feb. 7, 1929.

See Rubio, *Historia de la Regencia de Maria Christina* (1905) and Martín Alonso, *Diez y seis Años de Regencia* (1914).

CHRISTISON, SIR ROBERT, BART. (1797–1882), Scottish toxicologist and physician, was born in Edinburgh on July 18, 1797. He studied in London under John Abernethy and Sir William Lawrence, and in Paris, under P. J. Robiquet and M. J. B. Orfila. In 1822 he became professor of medical jurisprudence at Edinburgh. His *Treatise on Poisons* was published in 1829, and in 1829 he became medical officer to the Crown in Scotland, and from that time till 1866 he was called as a witness in many celebrated criminal cases, notably in the case of Burke and Hare (1829). Instructions drawn up by him for the examination of dead bodies for legal purposes became the accepted guide for the purpose. He may be said to have placed legal jurisprudence on a scientific basis. In 1832 he gave up the chair of medical jurisprudence for that of medicine and therapeutics, which he held till 1877. His work on the pathology of the kidneys and on fevers secured him a large private practice, and brought him many honours, including a baronetcy in 1871. Among his works are a treatise on *Granular Degeneration of the Kidneys* (1839) and a *Commentary on the Pharmacopoeias of Great Britain* (1842). Christison died at Edinburgh on Jan. 23, 1882.

The Life of Sir Robert Christison (1885–86), edited by his sons, contains his autobiography, with chapters on his work by Prof. Gairdner and T. R. Fraser.

CHRISTMAS (i.e., the Mass of Christ), in the Christian Church, the festival of the nativity of Jesus Christ. The history of this feast coheres so closely with that of Epiphany (q.v.), that what follows must be read in connection with the article under that heading.

Christmas was not among the earliest festivals of the Church, and before the 5th century there was no general consensus of opinion as to when it should come in the calendar, whether on Jan. 6, March 25, or Dec. 25. The earliest identification of Dec. 25 with the birthday of Christ is in a passage, otherwise unknown and probably spurious, of Theophilus of Antioch (c. 180), preserved in Latin by the Magdeburg centuriators (i. 3, 118), to the effect that the Gauls contended that as they celebrated the birth of the Lord on Dec. 25, so they ought to celebrate the

resurrection on March 25. A passage, almost certainly interpolated, in Hippolytus's (c. 202) commentary on Daniel iv. 23, says that Jesus was born at Bethlehem on Wednesday, December 25, in the 42nd year of Augustus, but he mentions no feast, and such a feast, indeed, would conflict with the then orthodox ideas. As late as 245 Origen (hom. viii. on Leviticus) repudiated the idea of keeping the birthday of Christ, "as if he were a king Pharaoh."

The first certain mention of Dec. 25 is in the Calendar of Philocalus (354), which was first published entire by Mommsen in *Abhandlungen d. sächs. Akad. d. Wissensch.* (1850), and is dealt with in Strzygowski's *Kalenderbilder des Chron. vom Jahre 354* (1888). This states that in "Year 1 after Christ the Lord Jesus Christ was born on Dec. 25, a Friday, and 15th day of the new moon"—though, in fact, Dec. 25 A.D. 1, was a Sunday. Here again no festal celebration of the day is attested.

Clement of Alexandria (c. 200) mentions several speculations on the date of Christ's birth, and condemns them as superstitious. Some chronologists, he says, alleged the birth to have occurred in the 28th year of Augustus, on 25 Pachon (an Egyptian month), i.e., May 20. Others assign it to 24 or 25 Pharmuthi (April 19 or 20). Clement himself sets it on Nov. 17, 3 B.C.; and the anonymous author of a Latin tract, *De Pascha computus* (written in Africa, 243), sets it, "by private revelation," on Wednesday, March 28, the supposed anniversary of the creation of the sun, which typifies the Sun of Righteousness. Similar symbolical reasoning led Polycarp (in a fragment preserved by an Armenian writer, Ananias of Shirak, dated before 160) to set His birth on Sunday, when the world's creation began, but His baptism on Wednesday, as the analogue of the sun's creation. On such grounds certain Latins as early as 354 may have transferred the birthday from Jan. 6 to Dec. 25, which was then a Mithraic feast, the *natalis invicti solis* or birthday of the unconquered Sun of Philocalus. The Syrians and Armenians, who clung to Jan. 6, accused the Romans of sun-worship and idolatry, contending that the feast of Dec. 25 had been invented by disciples of Cerinthus and its lectures by Artemon to commemorate the *natural* birth of Jesus. Ambrose (*On Virgins*, iii. ch. 1) seems to imply that as late as the papacy of Liberius (352-356) the Birth was feasted together with the Marriage at Cana and the Feeding of the Four Thousand, which were never feasted on any other day but Jan. 6.

Chrysostom, in a sermon preached at Antioch on Dec. 20, 386 or 388, says that the feast of Dec. 25 was known in the West, from Thrace as far as Cadiz, from the beginning. It certainly originated in the West, but spread quickly eastwards. In 353-361 it was observed at the court of Constantius; Basil of Caesarea (d. 379) adopted it; Honorius, emperor (395-423) in the West, told his mother and brother Arcadius (395-408) in Byzantium how the new feast was kept in Rome, separate from Jan. 6 with its own *troparia* and *sticharia*; and they adopted it. The patriarchs Theophilus of Alexandria, John of Jerusalem, and Flavian of Antioch, were won over to it under Pope Anastasius, 398-401. John or Wahan of Nice (Combefis *Historia monothelitarum*) affords the above details. The new feast was communicated by Proclus, patriarch of Constantinople, to Sahak, Catholicos of Armenia, about 440; and the Armenians within the Byzantine pale adopted it for about 30 years, but finally abandoned it, together with the decrees of Chalcedon, early in the 8th century. Many writers of the period 375-450, e.g., Epiphanius, Cassian, Asterius, Basil, Chrysostom and Jerome, contrast the new feast with that of the Baptism as that of the birth *after the flesh*, implying that the latter was generally regarded as a birth according to the Spirit. Usener notes that in 387 the new feast was reckoned according to the Julian calendar by writers of the province of Asia, who in referring to other feasts use the reckoning of their local calendars. As early as 400 in Rome an imperial rescript includes Christmas (with Easter and Epiphany) among the three feasts on which theatres must be closed. Epiphany and Christmas were not made judicial *non dies* until 534.

For some years in the West (as late as 353 in Rome) the birth feast was appended to the baptismal feast on Jan. 6, and was altogether supplanted by it in Jerusalem from about 360 to 440, when Bishop Juvenal introduced the feast of Dec. 25, which

about the same time was finally established in Alexandria. The *quadragesima* of Epiphany (i.e., the presentation in the Temple) continued to be celebrated in Jerusalem on Feb. 14 until the reign of Justinian. In most other places it had long before been put back to Feb. 2 to suit the new Christmas. But in Jerusalem, as Armenian historians record, the transference occasioned riots.

In Britain, Dec. 25 was a festival long before the conversion to Christianity, for Bede (*De temp. rat.* ch. 13) relates that "the ancient peoples of the Angli began the year on Dec. 25 when we now celebrate the birthday of the Lord; and the very night which is now so holy to us, they called in their tongue *modranecht* (*mōdra niht*), that is, the mothers' night, by reason we suspect of the ceremonies which in that night-long vigil they performed." In England the observance of Christmas was forbidden by act of Parliament in 1644; Charles II. revived the feast, but the Scots adhered to the Puritan view.

Outside Teutonic countries Christmas presents are unknown. Their place is taken in Latin countries by the *strenae*, French *étrennes*, given on New Year's Day. The setting up in Latin churches of a Christmas *crèche* is said to have been originated by St. Francis.

CHRISTMAS-BERRY (*Photinia arbutifolia* or *Heteromeles arbutifolia*), a handsome American shrub or small tree of the rose family (Rosaceae), called also California holly and toyon, native chiefly to the chaparral (*q.v.*) belt of the Sierra Nevada and Coast ranges. It grows from 5 to 15 ft. high and bears oblong, pointed, evergreen leaves and numerous small, white flowers in large, terminal clusters, followed in late autumn by bright red, holly-like fruits. It is very popular for Christmas decoration, being sold on the streets of Pacific-coast cities in the same manner as holly in the eastern United States.

CHRISTMAS ISLAND, a British possession annexed in Jan. 1889, and made part of the Straits Settlements in May 1900, situated in the eastern part of the Indian ocean (in 10° 25' S., 105° 42' E.), about 190m. S. of Java. It is quadrilateral; its greatest length is 12m., its extreme breadth 9 miles. The circumstances of its discovery are unknown, but it appears on a Dutch chart of 1666 under the name of Moni. Dampier visited it in 1688 and found it uninhabited. It was visited by H.M.S. "Flying Fish" in 1886, which discovered the anchorage now known as Flying Fish Cove. In 1891 an area of 6,000ac. was leased to George Clunies Ross, the owner of the Cocos-Keeling island and Sir John Murray, who in 1897 transferred their rights to a company. A thorough scientific investigation of the island was made in that year by C. W. Andrews of the British Museum at the cost of Sir John Murray. A district officer belonging to the Malayan civil service is in administrative charge of the island. (Pop., 1926, 1,043, almost all of whom are employees of the company which, in that year, exported 128,981 tons of phosphate of lime.)

The island is the flat summit of a submarine mountain of which some 14,000ft. are submerged and rather more than 1,000ft. are above sea-level. The slopes are steep, and within 20m. of the shore the sea reaches a depth of 2,400 fathoms. It consists of a central plateau descending to the water in three terraces. It is encircled by a reef which is always submerged, except at Flying Fish Cove, the only landing-place. On its northern aspect the central plateau has a raised rim having all the appearances of having once been the margin of an atoll. The surface of the plateau is studded with flat-topped hills and low ridges and reefs of limestone. On the rounded hills occurs the deposit of phosphate of lime which gives the island its commercial value. This has

doubtless been produced by the long-continued action of a thick bed of sea-fowl dung, which converted the carbonate of the underlying limestone into phosphate. There occurs on this island a series of tertiary deposits which appear to be unique. The whole series was evidently deposited in shallow water on the summit of a submarine volcano standing in its present isolation, round which the ocean bed has probably altered but a few hundred feet since the Eocene age. Thus, though the rocks of the southern coast of Java in their general character and succession resemble those of Christmas island, there lies between them an abysmal trough 18,000ft. in depth, which renders it scarcely possible that they were deposited in a continuous area, for such an enormous depression could hardly have occurred since Miocene times without involving Christmas island.

The flora is mainly angiospermous, but ferns and a few mosses, lichens and fungi, 17 of which are endemic, also occur, while a considerable number—not specifically distinct—form local varieties, nearly all of which present Indo-Malayan affinities. The fauna consists of 319 animals—54 only being vertebrates—145 of which are endemic. It is noteworthy that a large number show affinity with the species in the Austro-Malayan, rather than in the Indo-Malayan, their nearer, region. The climate is healthy, the temperature varying from 75° to 84° F. The prevailing wind is the south-east trade, which blows during the greater part of the year. There is an ample but not excessive rainfall.

See C. W. Andrews, *A Monograph of Christmas Island (Indian Ocean)* (1900).

CHRISTODORUS, of Coptos in Egypt, epic poet, flourished during the reign of Anastasius I. (A.D. 491–518). According to Suidas, he was the author of *Πάρτια*, accounts of the foundation of various cities; *Λυδιακά*, the mythical history of Lydia; *Ἰσαυρικά*, the conquest of Isauria by Anastasius; three books of epigrams; and many other works. In addition to two epigrams (*Anthol. Pal.* vii. 697, 698) we possess a description in hexameters of 80 statues in the gymnasium of Zeuxippus at Constantinople; this forms the second book of the Palatine Anthology. Some critics regard it as important for the history of art and a model of description; others consider it valueless.

See F. Baumgarten, *De Christodoro poeta Thebano* (1881), and his article in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1899); W. Christ, *Geschichte der griechischen Literatur* (1898).

CHRISTOPHE, HENRY (1767–1820), negro king of Haiti. After purchasing his freedom from slavery he played a prominent part in the insurrection against the French and in the rising of 1803. He was general-in-chief of the army during the short-lived government of Dessalines. Appointed president of Haiti in 1807, after the ensuing civil war, he was crowned king on June 2, 1812. Under him the country prospered, but his cruelty led to an insurrection, and being deserted by his troops he shot himself on Oct. 8, 1820.

See J. Vandercook, *Black Majesty* (1928).

CHRISTOPHER, SAINT (*Christophorus*, *Christoferus*), patron saint of ferrymen, is honoured in the Latin Church on July 25 and in the Greek Church on May 9. He appears to have been born a pagan in Syria, to have been baptized by Babylas, bishop of Antioch; he preached in Lycia and was martyred c. A.D. 250 during the persecution under the emperor Decius. The more conspicuous of the legends which collected about this nucleus of possibility are included in the Mozarabic *Breviary* and *Missal*, the best known being given in the *Golden Legend* of Jacopus de Voragine. According to this, Christopher was a giant in search of a master stronger than himself. He left the service of the king of Canaan because the king feared the devil, and that of the devil because the devil feared the Cross. He was converted by a hermit; but as he had neither the gift of fasting nor that of prayer, he decided to devote himself to a work of charity, and set himself to carry wayfarers over a bridgeless river. One day a little child asked to be taken across, and Christopher took him on his shoulder. When half way over the stream he staggered under what seemed to him a crushing weight, but he reached the other side and then upbraided the child for placing him in peril. "Had I borne the whole world on my back," he said, "it could not have

weighed heavier than thou!" "Marvel not!" the child replied, "for thou hast borne upon thy back the world and Him who created it!"

See Bolland, *Acta Sanct.* vi. 146; Guenebault, *Dict. iconographique des attributs, des figures et des légendes des saints* (Par. 1850); Smith and Wace, *Dict. of Christ. Biog.*

CHRISTOPHORUS, pope or anti-pope, elected in 903 against Leo V., whom he imprisoned. In January 904 he was treated in the same fashion by his competitor, Sergius III., who had him strangled.

CHRISTOPOULOS, ATHANASIOS (1772–1847), Greek poet, was born at Castoria in Macedonia. He studied at Buda and Padua, and became teacher of the children of the Vlach prince Mourousi. After the fall of Mourousi in 1811 he was employed by Prince Caradja, hospodar of Moldavia and Walachia, in drawing up a code of laws for that country. On the removal of Caradja, he retired into private life and devoted himself to literature. He wrote drinking songs and love ditties which are very popular among the Greeks. He also wrote *Politika Parallela* (a comparison of various systems of government), translations of Homer and Herodotus, a tragedy and some philological works on the connection between ancient and modern Greek.

His *Hellenika Archaiologemata* (Athens, 1853) contains an account of his life.

CHRIST'S HOSPITAL (the Blue Coat school) was originally one of three royal hospitals in the city of London, founded by Edward VI. Christ's hospital was specially devoted to fatherless and motherless children. The buildings of the monastery of Grey Friars, Newgate street, were appropriated to it; liberal public subscription added to the king's grant endowed it richly, and the mayor, commonalty and citizens of London were nominated its governors in its charter of 1552. Not long after its opening Christ's was providing home and education (or, in the case of the very young, nursing) for 400 children. The popular name of the Blue Coat school is derived from the dress of the boys—originally (almost from the time of the foundation) a blue gown, with knee-breeches, yellow petticoat and stockings, neck-bands and a blue cap. The petticoat and cap were given up in the middle of the 19th century, and thereafter no head-covering was worn. In 1902 the buildings on the Newgate street site were vacated by the school, which was moved to extensive new buildings at Horsham. It includes a preparatory school for boys, established in 1683 at Hertford, where the buildings have been greatly enlarged for the use of the girls' school on the same foundation.

CHRISTUS, PETER (c. 1400–1473). A Flemish painter, born at Baerle in North Brabant soon after 1400. He became a citizen of Bruges in 1444. His style was modelled on that of the Van Eycks. His execution was conscientious but lacked the vital qualities of his great forerunners. He signed his pictures "Petrus XPR or XPI." The following paintings bear his signature and are dated:—"The Portrait of Edward Grimston" in the Earl of Verulam's collection, Gorhambury, England (1446); "The Portrait of a Monk" in the collection of Marquis de Dos Aguas at Valencia (1446); "The Interior of a Goldsmith's Shop" in the possession of Philip Lehmann at New York (1449); a half length "Madonna Nursing the Child" at Schloss Vollrads near Wiesbaden (1449); two wings of an altar piece representing "The Nativity," the "Annunciation," and the "Last Judgment" at the Berlin museum (1452); the "Madonna with Saints" at the Stäedel, Frankfurt (1457). Besides these a number of unsigned pictures are ascribed to him, among which are two fine portraits, one in the Salting collection at the National Gallery, London, the other at the Berlin museum; and "The Nativity" in the possession of Henry Goldman at New York. The last known picture by Christus is the "Pietà" in the Brussels gallery (c. 1460). An earlier version of the same subject is in the New York museum. There is reason to believe that Christus visited Italy and taught Antonello da Messina the Van Eyck method. He had a son Sebastian and a grandson Peter II. who were both painters.

See W. H. Weale, *Peintres Brugeois, Les Cristus* (1909); Sir Martin Conway, *The Van Eycks and their Followers* (1921); Max Friedländer, *Petrus Christus* (1924). (I. A. R.)

CHRISTY, HENRY (1810–1865), English ethnologist, was born at Kingston-on-Thames on July 26, 1810. From 1850–58 he travelled in Europe and America, studying ethnology. In 1858 the discoveries by Boucher de Perthes of flint implements in France and England were first held to have proved the great antiquity of man. Christy joined the Geological Society, and with his friend Edouard Lartet explored the caves in the valley of the Vézère. An account of the explorations appeared in *Comptes rendus* (Feb. 29, 1864) and *Transactions of the Ethnological Society of London* (June 21, 1864). He died, on May 14, 1865, leaving a half-finished book, entitled *Reliquiae Aquitanicae*, which was issued in parts and completed first by Lartet and, after the latter's death in 1870, by Professor Rupert Jones. Christy left his magnificent archaeological collection to the nation. In 1884 it was placed in the British Museum.

CHROMATES AND DICHROMATES, inorganic chemical compounds, or salts, in which the element chromium appears as part of the acid or "negative" component of the salt. Chromium trioxide, CrO_3 , commonly but incorrectly termed chromic acid, forms no crystalline hydrates with water, though its strongly acid aqueous solution is supposed to contain chromic acid, H_2CrO_4 . The salts of this acid are known as chromates. Only normal salts, for example potassium chromate, K_2CrO_4 , are known, which are analogous to and frequently isomorphous with normal sulphates. Acid or hydrogen salts, analogous to potassium bisulphate, KHSO_4 , are unknown. If an equivalent of acid be added to a solution of a normal chromate, the colour changes from yellow to orange-red, and from the mixture dichromates, for example potassium dichromate, $\text{K}_2\text{Cr}_2\text{O}_7$, alone can be isolated. If further equivalents of acid or, better, chromium trioxide, be added, the solutions become darker red and trichromates such as potassium trichromate, $\text{K}_3\text{Cr}_3\text{O}_{10}$, and tetrachromates such as potassium tetrachromate, $\text{K}_4\text{Cr}_4\text{O}_{13}$, are formed. The solid tri- and tetrachromates are decomposed on solution in water to form dichromates and free chromic acid.

Normal chromates are known of nearly all the stronger bases, both organic and inorganic, and are generally yellow. Ammonium, lithium, sodium, potassium, cuprous, cupric, rubidium, caesium, magnesium, calcium, zinc, cobalt and nickel chromates are soluble in water; strontium and the "rare-earth" chromates are sparingly soluble in water; mercuric chromate is decomposed by water, while silver, thallous, mercurous, cadmium, barium and lead chromates are insoluble in water. With the exception of cuprous, mercurous and magnesium dichromates which are unknown, all the metals forming soluble chromates also yield soluble red dichromates. Barium, lead and silver dichromates are known but are decomposed by water to form normal chromates and chromic acid. Cadmium dichromate is soluble in water, whereas mercuric and thallous dichromates are insoluble. Dark red trichromates are known of ammonium, sodium, potassium, rubidium, caesium, thallous, zinc, cadmium and nickel. Dark red tetrachromates are known of ammonium, sodium, potassium, rubidium and caesium.

Chromates and polychromates are readily reduced by hydrochloric acid, sulphurous acid, hydrogen sulphide, ferrous salts, alcohol, etc., with formation of chromic salts or hydroxide. The chromates of the strongly basic elements are not readily decomposed by heating, but those of the feebler bases yield chromium sesquioxide and oxygen. Ammonium chromate, on heating or exposure to air, loses ammonia and yields the dichromate, which decomposes with explosive violence on further heating, leaving a residue of chromium sesquioxide, while nitrogen, ammonia, oxides of nitrogen, water and oxygen are also formed.

On treatment of chromates or dichromates with concentrated cold solutions of the halogen acids, or phosphorous halides, salts are obtained, derived from hypothetical half-acid halides; for example, hydrochloric acid and potassium dichromate yield potassium chlorochromate, a salt of the unknown chlorochromic acid HCrO_3Cl or $\text{CrO}_2\text{Cl}\cdot\text{OH}$, the half-acid chloride of chromic acid $\text{CrO}_2(\text{OH})_2$. Fluorochromates, chlorochromates, bromochromates and iodochromates of some of the strong bases are known. If chromates or dichromates are treated with a large excess of hydrofluoric or hydrochloric acid, chromyl fluoride, CrO_2F_2 , and chromyl

chloride, CrO_2Cl_2 , are formed. These compounds, which are red volatile liquids yielding red vapours, are the acid fluoride and acid chloride of chromic acid. The bromine and iodine analogues are unknown.

Though chromates and dichromates are readily decomposed by warm solutions of hydrogen peroxide to form oxygen and chromic salts or chromic hydroxide, cold solutions yield little or no oxygen and form peroxidized compounds, nearly all of which yield hydrogen peroxide by suitable treatment and all readily evolve oxygen. It is accordingly inferred that all contain sexavalent chromium as in chromates and dichromates, the extra equivalents of oxygen being in the same form as in hydrogen peroxide. The highest stage of peroxidation is found in the red perchromates of the general formula R_3CrO_8 . These salts are obtained by the action of 30% hydrogen peroxide solutions on alkaline solutions of the chromates at low temperatures. They are unstable at ordinary temperatures and occasionally evolve oxygen explosively. The acid corresponding to these salts has not been isolated. When 97% hydrogen peroxide is added at -30° to chromium trioxide, a dark blue crystalline acid is formed, having the empirical formula $\text{H}_7\text{CrO}_{10}$ or $\text{H}_3\text{CrO}_8\cdot 2\text{H}_2\text{O}$. An intense blue coloration is formed on adding hydrogen peroxide to an acidified solution of a chromate, the reaction being sufficiently delicate to detect traces of either reagent. The blue colour is extracted by ether, and the ethereal solution on neutralization by alkalis yields dark blue salts. These salts have the general formula RH_2CrO_7 , and are as unstable as the more oxygenated red salts. If the red or blue salts are treated with excess of an organic base such as pyridine, blue or violet salts are obtained having the general formula RCrO_5 . If the red perchromates are heated with ammonia to about 40° , or with potassium cyanide solution, derivatives of a chromium peroxide of the formula CrO_4 or Cr_2O_8 are obtained. This peroxide may be regarded as an acid anhydride, formed by the loss of a molecule of hydrogen peroxide from two molecules of the acid HCrO_5 , or one molecule of the dimeric acid $\text{H}_2\text{Cr}_2\text{O}_{10}$. The derivatives of this peroxide yield oxygen and chromates with alkalis, and oxygen, hydrogen peroxide and chromic salts with acids.

Analytical.—Chromates and dichromates are readily detected by the blue coloration (above) or by formation of chromyl chloride with hydrochloric acid. Soluble chromates may be precipitated and estimated as barium chromate, or precipitated as mercurous chromate and ignited to chromium sesquioxide. Volumetrically, chromates and dichromates may be estimated by reduction with ferrous salts or acidified potassium iodide solution. Dichromates may be detected in the presence of chromates by the formation of a brown precipitate on addition of a hot sodium thiosulphate solution. Free chromic acid may be detected in presence of chromates and dichromates by the liberation of iodine from neutral potassium iodide solution.

Uses.—Chromic acid, chromates and dichromates are used industrially in the production of pigments, dyes and dye intermediates, in photography, in tanning, in water-resistant glues and cements, and in the production of inorganic pigments such as barium chromate (lemon chrome), lead chromate (chrome yellow), basic lead chromate, $\text{PbCrO}_4\cdot\text{PbO}$ (chrome red or orange), and various basic zinc chromates (zinc yellow and, mixed with Prussian blue, zinc green). The alkali dichromates find extensive application as mordants in dyeing.

Chromates and dichromates are all therapeutically dangerous, being strongly caustic and destructive of the red corpuscles of the blood. They have, however, been used as external caustics and antiseptics for ulcers, etc., with success. (J. D. M. S.)

CHROMATIC, a term meaning "coloured," chiefly used in science, particularly in the expression "chromatic aberration" or "dispersion" (see ABERRATION). In Greek music *χρωματική μουσική* was one of three divisions—diatonic, chromatic and enharmonic—of the tetrachord. Like the Latin *color*, *χρῶμα* was often used of ornaments and embellishments, and particularly of the modification of the three *genera* of the tetrachord. The chromatic, being subject to three such modifications, was regarded as particularly "coloured." To the Greeks chromatic music was sweet and plaintive. From a supposed resemblance to the notes

of the chromatic tetrachord, the term is applied to a succession of notes outside the diatonic scale, and marked by accidentals. A "chromatic scale" is thus a series of semi-tones.

CHROMATOMETER or **TINTOMETER**, an instrument for standardizing the *intensity* and *hue* of a given colour (*q.v.*). The specimen is compared with a standard by viewing the two simultaneously and interposing in front of the standard various standard coloured plates until a match is obtained. Instead of the plates, strata liquids of the three primary colours may be used. (See also **COLORIMETER**.)

CHROME STEEL: see **IRON AND STEEL**.

CHROMITE, a member of the spinel group of minerals; an oxide of chromium and ferrous iron, FeCr_2O_4 . It is the chief commercial source of chromium and its compounds. It crystallizes in regular octahedra, but is usually found as grains or as granular to compact masses. In its iron-black colour with submetallic lustre and absence of cleavage it resembles magnetite (magnetic iron-ore) in appearance, but differs from this in being only slightly if at all magnetic and in the brown colour of its powder. The hardness is $5\frac{1}{2}$; specific gravity 4.5. The theoretical formula FeCr_2O_4 corresponds with chromic oxide (Cr_2O_3) 68%, and ferrous oxide 32%; the ferrous oxide is, however, usually partly replaced by magnesia, and the chromic oxide by alumina and ferric oxide, so that there may be a gradual passage to picotite or chrome-spinel. Much of the material mined as ore does not contain more than 40 to 50% of chromic oxide. The earliest worked deposits of chromite were those in the serpentine of the Bare hills near Baltimore, Md.; and it is now mined in Southern Rhodesia, Quebec, New Caledonia, India, Greece, Asia Minor, Ural Mountains, California, etc. It abounds in Chester county, Pa., at Hoboken, N.J., and in various parts of North Carolina. Chrome-iron ore is largely used in the preparation of chromium compounds for use as pigments (chrome-yellow, etc.), and in calico-printing.

CHROMIUM is a metallic chemical element, called so from the Greek $\chi\rho\acute{o}\mu\alpha$, colour, on account of the varied colours of its compounds. In 1798, L. N. Vauquelin and M. H. Klaproth simultaneously and independently discovered a new element in addition to lead in the mineral crocoisite or crocoite (lead chromate, PbCrO_4) first described by Lehmann in 1762. The metal was not isolated, however, until 1859, when F. Wöhler obtained small quantities of it by reduction of the trichloride with potassium. Owing to the difficulty of reduction and of electro-deposition, the metal remained a chemical curiosity for many decades, though it is now produced on a large scale for use in stainless and alloy steels. Its symbol is Cr, and it has an atomic number of 24 and an atomic weight of 52.01. Owing to the possession of six valency electrons it has a maximum of valency of six.

Occurrence and Production.—The metal is not found free in nature, and, though the element has a minimum valency of two, all of the ores contain trivalent or hexavalent chromium. The chief mineral from which the metal and commercial chromium compounds are obtained is chromite, or chrome iron ore, which consists largely of ferrous chromite, $\text{Fe}(\text{CrO}_2)_2$ or $\text{FeO}, \text{Cr}_2\text{O}_3$. This ore is widely distributed, but Rhodesia, the United States and India are the chief producers. In addition to chromite and crocoisite, chromium is also found as sesqui-oxide in chrome ochre, Cr_2O_3 , as potassium chromate, K_2CrO_4 , as redingtonite (a hydrated sulphate), as phospho-chromates, as basic chromates, as ferrous thiochromite, $\text{Fe}(\text{CrS}_2)_2$, and in various other combinations. The green colour of emerald, serpentine, chrome-mica and chrome-garnet is due to chromium, as is also the red colour of ruby, and some sapphires and spinels.

The chromium compounds of commerce are practically all derived from the alkali chromates and dichromates (*q.v.*), obtained by roasting chromite with lime in an oxidizing atmosphere and subsequent treatment with an aqueous solution of alkali sulphate. Metallic chromium is obtained by H. Goldschmidt's aluminothermic process, in which chromium sesquioxide or potassium dichromate is reduced by heating with aluminium powder. It may also be obtained by electro-deposition from solutions of chromic sulphate mixed with much "chromic acid," CrO_3 , this method being used for plating iron and steel. Pure chromium

may be obtained by reduction of the sesquioxide at $1,500^\circ \text{C}$ with pure hydrogen, while pure chromium amalgam is obtained on treating concentrated solutions of chromic chloride with sodium amalgam. If the amalgam be distilled at 350°C in hydrogen, or 300°C *in vacuo*, a residue of pyrophoric (spontaneously inflammable) chromium powder remains. Ferro-chrome alloys may be obtained by direct smelting of chromite, with or without addition of chromium sesquioxide, by means of carbon in the electric furnace. The natural or enriched ferro-chrome alloy is utilized in the manufacture of stainless steels and chrome alloy steels.

Properties.—Chromium is a steel-white metal, harder than iron, cobalt or nickel, and capable of taking a brilliant polish. It is non-magnetic at ordinary temperatures, but becomes magnetic at -15°C . The melting point is $1,540^\circ \text{C}$ and the boiling point $2,200^\circ \text{C}$, the melting point being higher than that of manganese, iron, cobalt or nickel, though the boiling point is less than that of any of these. The density of the metal varies from 6.7 to 7.1. The electrolytically deposited metal occludes about 250 times its volume of hydrogen. It crystallizes either as rhombohedra or tetragonal pyramids, and X-ray examination discloses that it can exist in two allotropic modifications.

Though pyrophoric in the finely divided condition, chromium in the massive form is not affected by moist air, and only very slowly by dilute acids. Neither fuming nitric acid nor aqua regia attacks it, but with hot concentrated sulphuric acid it gives sulphur dioxide and a dark solution. Warm dilute hydrochloric or sulphuric acid slowly dissolves the metal, hydrogen being evolved with the formation of chromous salts. Heated in hydrogen chloride, the metal yields crystalline colourless chromous chloride, while chlorine yields violet chromic chloride. Chromium is not attacked even by fused alkalis, but fused potassium nitrate or chlorate oxidizes it rapidly to potassium chromate. Heated with sulphur or in hydrogen sulphide, chromium yields chromous sulphide, CrS , whereas with carbon, silicon or boron, various carbides, silicides or borides are formed. Though a chromium carbonyl, $\text{Cr}(\text{CO})_6$, is known, it is not formed by heating chromium in carbon monoxide, but by treating chromic chloride with carbon monoxide in the presence of magnesium phenyl bromide. Pyrophoric chromium combines directly with nitrogen to form a magnetic nitride. Chromium amalgam also combines with nitrogen to form chromic nitride (CrN), chromous nitride (Cr_2N_2) being formed by heating chromium to 850° in ammonia.

Chromium is known in five conditions of oxidation, having all valencies from two to six. The salts of bivalent chromium (chromous) are all powerful reducing agents, thus resembling the bivalent salts of vanadium and titanium. Chromous salts of nearly all the commoner acids have been prepared and are generally colourless in the anhydrous state and blue when hydrated or in solution. Chromous fluoride (CrF_2) is green; potassium chromous carbonate, $\text{K}_2\text{Cr}(\text{CO}_3)_2 \cdot 3\text{H}_2\text{O}$, is yellow; and chromous acetate, $\text{Cr}(\text{CH}_3\text{CO}_2)_2$, is red. Chromous sulphate, which is isomorphous with copperas, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, also yields double sulphates of the type $\text{CrSO}_4 \cdot \text{R}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$, where R is a monovalent metal.

Chromic Compounds.—Chromic salts, derived from the trivalent form, are very stable and are neither reducing nor oxidizing agents. They can be reduced or oxidized only with difficulty, to the chromous stage by zinc and acid, and to the chromate stage by alkaline peroxides, hypochlorites or hypobromites. Chromates, like permanganates, are reduced by hydrogen peroxide on warming in acid solution, but the reduction is not carried to the bivalent stage, chromic salts only being formed. Chromic oxide, Cr_2O_3 , is a much feeble base than chromous oxide, CrO , and chromic salts are consequently always hydrolysed in solution and have an acidic reaction. Chromic oxide, in fact, has decided acidic properties and yields salts with alkalis, of which barium chromite, $\text{Ba}(\text{CrO}_2)_2$, is a characteristic example. This acidic nature of chromic oxide gives rise to an extended series of natural and artificial gem-like minerals called chrome-spinels, for example, nickel spinel, $\text{NiO}, \text{Cr}_2\text{O}_3$, brilliant green crystals belonging to the cubic system. All chromic salts are highly coloured, most be-

ing green or violet, though the chromicyanides are yellow or orange, $R_3Cr(CN)_6$, and the chromithiocyanates are ruby-red, $R_3Cr(CN)_6 \cdot 4H_2O$. Chromium yields purple double-sulphates of the type $R_2SO_4 \cdot Cr_2(SO_4)_3 \cdot 24H_2O$, which are alums (*q.v.*).

Chromic salts closely resemble cobaltic salts in their capacity for forming double and complex salts. In nearly all these salts it is possible to discern six non-ionising groups attached or co-ordinated to the chromium atom, which is accordingly said to possess the co-ordination number six like cobalt. In the case of the ammonia-addition compounds (*see* AMMINES) whole series are known which are indistinguishable in appearance and general properties from the corresponding cobaltammines. These comprise such types as luteo-chromic ammines, $Cr(NH_3)_6Cl_3$, purpureo-ammines, $CrCl(NH_3)_5SO_4$, and among many others, praseo-ammines, $CrCl_2(NH_3)_4NO_3$. Complex salts are also formed by replacing ammonia with pyridine, ethylenediamine, and similar organic bases. Some of these complex salts have been shown to be capable of existing in optically active forms, thus proving that the groups co-ordinated to the chromium atom are not planar but have a spatial distribution which is octahedral. The use of chrome alum and chromic fluoride as mordants in fixing soluble dyestuffs on fabrics has been shown to be due to the capacity of the chromium atom to enter into complex formation with the dyestuffs, yielding highly insoluble compounds, often of different colour from the combined dyestuff, firmly fixed on or in the fibre. It is probable that the use of chromium compounds in tanning is due to complex reaction with the organic substances present in hides.

F. Hein has recently proved that chromium can possess the valency four, a fact long suspected from the existence of an oxide having the empirical formula CrO_2 , hitherto regarded as chromous chromate, $CrCrO_4$, or as basic chromic chromate, $(CrO)_2CrO_4$. Hein prepared triphenyl chromium hydroxide $(C_6H_5)_3CrOH$, a powerfully alkaline base, yielding a series of neutral salts such as the perchlorate, Ph_3CrClO_4 . He also prepared compounds containing chromium with valency five, for example, tetraphenyl chromium hydroxide, and salts such as the iodide, Ph_4CrI , were isolated. The only inorganic compounds of chromium known with the valency of five are the oxytrichloride, $CrOCl_3$ and its derivatives.

Without exception all inorganic compounds containing chromium with valency six contain oxygen, and are derivatives of the trioxide, CrO_3 , commonly but improperly called chromic acid. Chromium trioxide is properly the anhydride of the hypothetical acids, H_2CrO_4 and $H_2Cr_2O_7$, analogous to sulphuric acid and pyrosulphuric acid. The salts of these two acids, chromates and dichromates respectively, are known for the majority of the stronger bases. (*See* CHROMATES and DICHROMATES.) Chromic anhydride was originally obtained by the hydrolysis of chromyl fluoride, CrO_2F_2 , but is nowadays made commercially by the action of concentrated sulphuric acid on solutions of chromates or dichromates, usually potassium dichromate. It forms dark red rhombic needles, which decompose at 330° evolving oxygen and leaving green chromium sesquioxide, Cr_2O_3 . It is extremely soluble in water, giving acid solutions from which chromates and dichromates can be produced.

Analysis and Uses.—Chromium can be detected in compounds by the formation of a green borax bead, by the yellow colour of chromates formed on fusion with potassium nitrate, by the formation of red chromyl chloride, and by the blue colour of perchromic acid. Dichromates may be detected in the presence of chromates by the brown precipitate formed on addition of a hot solution of sodium thiosulphate, while free chromic acid may be detected in the presence of dichromates by the liberation of iodine from a solution of potassium iodide. Chromium is separated in group analysis from aluminium and ferric hydroxides by oxidation to soluble chromate with sodium peroxide. Gravimetrically, chromium is usually precipitated with ammonia as chromic hydroxide, and ignited to the sesquioxide. Volumetrically, as chromate or dichromate, it may be estimated by reduction with ferrous salts or acidified potassium iodide.

Metallic chromium is used industrially in the manufacture of

steels, and is a common constituent of many ferrous and non-ferrous alloys. Stainless steel, commonly used for rustless cutlery, tools and machinery, is essentially a ferro-chrome alloy, the percentages of chromium and iron usually being about 13 and 86 respectively. As a protective surface for metals, chromium is also used in the form of plate which may be applied electrolytically or by welding. Chromium compounds, usually dichromates or chrome alum, are used in the manufacture and application of dyes and pigments, in tanning hides, and in photography. Chromic salts are practically non-toxic, but the soluble chromates and dichromates are therapeutically dangerous.

CHROMOLITHOGRAPH: *see* LITHOGRAPHY; COLOUR PRINTING.

CHROMOSOME. So called on account of their affinity for certain dyes, the chromosomes are minute bodies seen in the dividing cells of which the bodies of animals and plants are composed. Their characteristic configurations and remarkable behaviour in cell division, in the process of development, and in the union and formation of the reproductive elements has been the subject of a large body of research, since their discovery in 1873 by Anton Schneider, Flemming, Bütschli and others. The progress achieved during the three decades that followed their discovery made it possible, when Mendel's law of segregation was rediscovered in the opening years of the present century, to identify the structural mechanism predicted by him. From that time to the present day, intensive study of the behaviour of the chromosomes in relation to breeding experiments have resulted in the building up of one of the most spectacular generalizations of modern biology. An exposition of this chromosome hypothesis is given in the article CYTOLOGY. The word was first used by Waldeyer (1888). (*See* also HEREDITY.) (L. T. H.)

CHROMOSPHERE is the name which was given by Sir Norman Lockyer in 1868 (at the suggestion of Sharpey, then secretary of the Royal Society) to the layer of the sun's atmosphere, just outside the photosphere, which is observed visually when the sun is totally eclipsed and is spectroscopically observable at other times. Observations of the chromosphere had in fact been made before 1868. Thus Young (*The Sun*, 1882) mentions that Capt. Stannyan, in a report on the eclipse of 1706 observed by him at Berne, noticed "a blood-red streak of light visible for six or seven seconds upon the western limb," just before the emergence of the sun. It was observed also by Halley in 1715, and by Arago, Airy, Secchi and others at eclipses in the 19th century. Attention was however directed mostly at that time to solar prominences, and the chromosphere escaped serious study. In 1868 Janssen and Lockyer independently discovered that solar prominences, hitherto only observed at total eclipses, could be seen in full daylight by means of the spectroscope—the principle being that the white light from the sky surrounding the sun's disc was weakened by dispersion on passing through the spectroscope, whilst any monochromatic constituent of the light from the prominences passed through undispersed and gave rise to a bright line. Lockyer shortly afterwards (Nov. 5, 1868) noticed that the prominences jutted out from a continuous spherical envelope surrounding the sun. This envelope was at all times visible in the red (C or $H\alpha$) and blue (F or $H\beta$) lines of hydrogen and in the yellow (D_β) line of the then unidentified element helium. It was to this continuous envelope that Lockyer gave the name chromosphere, in reference to the colour effects seen in the spectroscope.

At a time of total solar eclipse, at the moment of second contact, the chromosphere becomes visible as a thin red crescent, some 10 sec. in thickness, on the east side of the disc. The advancing moon rapidly covers up the layer, which reappears at the western limb just before third contact. The red colour is due to the visual dominance of the $H\alpha$ line of hydrogen.

Astronomers soon recognized that in the chromosphere they must be viewing tangentially the upper layers of the same gases which, when projected against the bright disc, produce the ordinary Fraunhofer absorption spectrum of sunlight, and it was

natural to look for confirmation of this. The complete spectrum of the light from the chromosphere might be expected to correspond with the Fraunhofer spectrum, a bright line in the chromospheric spectrum corresponding to each dark line in the Fraunhofer spectrum. This was first verified by C. A. Young at the total eclipse of Dec. 22, 1870. Placing the slit of his spectro-scope tangential to the advancing limb of the moon, he saw the Fraunhofer spectrum suddenly replaced by a spectrum of bright lines which lasted only two or three seconds. This spectrum was hence called by Young the "flash spectrum." In Young's own words, "as the moon advances, making narrower and narrower the remaining sickle of the sun's disc, the dark lines of the spectrum remain sensibly unchanged though becoming somewhat less intense. A few however begin to fade out, and some even turn partially bright a minute or two before totality begins. But the moment the sun is hidden, through the whole length of the spectrum, in the red, the green, the violet, the bright lines flash out by hundreds and thousands, almost startlingly; as suddenly as stars from a bursting rocket, and as evanescent, for the whole thing is over in two or three seconds."

Photography was first successfully applied to the photography of the flash spectrum by A. Fowler and W. Shackleton at the eclipse of April 16, 1893. The flash spectrum may be observed by the use of a tangential slit, as in Young's original observation. But the crescent of atmosphere left exposed by the moon's disc during the period of the flash is so thin that it behaves as a crescent-shaped slit. A direct photograph of the flash spectrum with a prismatic camera without slit reveals a series of crescents, one corresponding to each bright line in the flash spectrum. (See illustration under article ECLIPSE.) Each gives an image of the chromosphere and prominences in the corresponding radiation. The thicker the atmosphere as viewed in the light of a particular radiation, the longer will be the arc in the photograph, and it is a matter of simple geometry to deduce the height of the chromosphere in any given radiation from a measurement of the distance from cusp to cusp, using the known diameters of the sun and moon. The following table shows chromospheric heights derived in this way by Lockyer (eclipse of 1898), Mitchell (1905) and Davidson and Stratton (1926).

Heights of Elements in Chromosphere from Lengths of Arcs

| Element. | Radiation. | Lockyer. 1899 | Mitchell. 1905 | Davidson and Stratton. 1926 |
|---------------------|--|--------------------------|------------------------------|-----------------------------------|
| H . . | $\lambda 6563$ H α $\lambda 4861$ H β $\lambda 4341$ H γ | Km. 7500 | Km. .. 8000 8000 | Km. 8400 8400 8000 |
| He . . | $\lambda 4713$ $\lambda 5876$ (D $_2$) $\lambda 4471$ $\lambda 4026$ | 6500 4500 | 3900 7500 7500 6000 | 6000 7500 7400 4400 |
| He ⁺ . . | $\lambda 4686$ | .. | 1580 | 2200 |
| Na . . | $\lambda 5896$, $\lambda 5890$ (D $_1$, D $_2$) | .. | 1200 | 1000 |
| Ca . . | $\lambda 4227$ | 3500 | 5000 | 2500 |
| Ca ⁺ . . | $\lambda 3968$, $\lambda 3933$ (H, K) | 9500 | 14000 | 9200 |
| Sr ⁺ . . | $\lambda 4215$, $\lambda 4077$ | 4500 | 6000 | 5200 |

As regards wave-length, the flash spectrum is an almost exact copy of the Fraunhofer spectrum. The Balmer series of hydrogen extends however much further (Stratton and Davidson at Sumatra, in 1926, observed 36 members of the series); also helium is prominent in the flash, whilst it only appears fitfully and faintly in the Fraunhofer spectrum. But the intensities of the lines in the flash are markedly different from the intensities in the Fraunhofer spectrum. Lines faint in the Fraunhofer spectrum give rise to short intense arcs in the flash; this is easily explained since the faint lines in the Fraunhofer spectrum are probably produced

by low-lying vapours at a high temperature, which accordingly shine brightly when viewed tangentially. But in addition many lines are enormously increased in intensity in the flash. It was pointed out by Lockyer that such lines are almost invariably "enhanced" lines, *i.e.*, lines which are relatively strengthened from arc spectra to spark spectra. For example the D-lines of sodium (arc lines) are relatively inconspicuous in the flash; the blue line $\lambda 4227$ of calcium is much less intense and extends to a smaller height than the H and K lines; the enhanced lines of iron, scandium, titanium and chromium are all strengthened in the flash, and usually extend to greater heights than the unenhanced lines. The flash spectrum, in fact, resembles in many ways the spectrum of stars much hotter than the sun. This was for many years a difficulty, for it was hard to believe that the high-level chromosphere could be hotter than the low-level reversing layer.

The explanation was given by Megnad Saha in 1920. Enhanced lines are now known to be due to the ionized atom, *i.e.*, the atom which has lost one or more electrons, and Saha showed that ionization was promoted not only, as in Lockyer's experiments, by high temperature but also by low pressure. At high temperatures the process of the dissociation of an atom into an electron and a positive ion goes on of its own accord, according to the reversible equation

until a balance is obtained between the rate of dissociation and the rate of recombination. Reduction of pressure reduces the rate of recombination, whilst leaving the rate of ionization unchanged, and so favours an increased degree of ionization. Saha showed that at a given temperature and pressure the degree of ionization was calculable, given the ionization potential of the atom. The following table gives the percentage ionization of calcium at 5,000° C. at the pressures mentioned:—

| | | | | | | |
|------------------------|-----------|-----------|-----------|-----------|-----------|-----------|
| Pressure (atmospheres) | 10^{-1} | 10^{-2} | 10^{-3} | 10^{-4} | 10^{-5} | 10^{-6} |
| Percentage ionization | 6.5 | 20.2 | 54.5 | 90 | 99 | (100). |

The pressure at the base of the chromosphere is probably less than 10^{-6} atmosphere, and so in the high-level chromosphere calcium must be almost completely ionized. The spectrum must therefore be that of the ionized atom, not the neutral atom; hence the predominance of enhanced lines in the chromospheric spectrum. Similar calculations apply to other elements. The D-lines of sodium, for example, which are due to the neutral atom, are not found in the upper chromosphere, because any sodium there would be completely ionized; the lines of the ionized atom are too far in the ultra-violet to be observable.

The question remains why the chromosphere should extend to such great heights in certain elements. Gravity at the solar surface is some 27 times as powerful as at the earth's surface, and it is readily calculated that under gravity only the solar atmosphere would have a thickness which would be measured in tens of kilometres instead of thousands. The explanation is that the atoms are largely supported against gravity by radiation pressure. When an atom absorbs a quantum of light, and thereby undergoes a transition from one stationary state to another, it experiences a blow in the direction in which the light was moving. In the case of an atom near the sun, this blow will be in an outward direction. After a short interval the atom must omit the quantum, suffering thereby a blow from the recoil, but the recoil-blows will be random in direction and will neutralize one another on the average. The net result is that in a succession of absorptions and emissions the atom experiences a series of outward blows. The atom of ionized calcium in the high-level chromosphere, for example, experiences some 20,000 such blows per second, and this is just sufficient to keep it suspended against gravity.

In the absence of a chromosphere, radiation pressure on calcium atoms at the sun's surface would exceed gravity. Ionized calcium atoms would be expelled from the sun until a screen of atoms was brought into existence sufficiently thick to shield the atoms at the highest level from the direct radiation of the sun to such an extent that radiation pressure was reduced to equality with gravity. This is presumably the mode of formation of the

chromosphere; it is called into existence to redress a dynamical want of balance. The extent to which different kinds of atoms are hoisted in this way by radiation pressure depends on the atomic structure, the position of the lines in the spectrum and the stationary states from which they originate. On these principles it has been found possible to account, generally speaking, for the main features of the chromosphere, and in particular to explain why heavy atoms are sometimes found higher up than the light ones. At high levels in the chromosphere the pressure is very small, probably only some 10^{-12} atmosphere, and collisions of atoms with one another are quite infrequent. The equilibrium of an atmosphere under gravity and radiation pressure differs considerably from that under gravity and a pressure gradient, and to it the name "chromospheric equilibrium" has been applied.

The intensity of H and K radiation to which a high-level atom of calcium is subject is simply the residual intensity in the centre of the dark Fraunhofer H and K lines. Observations of this intensity combined with the theory of equilibrium under radiation pressure lead to an evaluation of the period (1.8×10^{-8} seconds) during which a calcium atom remains in an excited state. Chromospheric theory thus has an important by-product in atomic theory, as the period of excited life of an atom should be an atomic constant independent of solar conditions. Chromospheric theory has further suggested an explanation of the motions observed in solar prominences, and of the emissions of layers of gases from Novae.

An outstanding problem is the rotation of the chromosphere. The high-level chromosphere rotates round the sun's axis faster than the reversing layer, and moreover does not share the polar retardation experienced by the latter. No satisfactory explanation of this has yet been suggested.

BIBLIOGRAPHY.—General accounts of the chromosphere are contained in the following standard works: E. Pringsheim, *Physik der Sonne* (1910); C. G. Abbot, *The Sun* (1911); H. Dingle, *Modern Astrophysics* (1924); S. A. Mitchell, *Eclipses of the Sun* (1924); F. J. M. Stratton, *Astronomical Physics* (1925). See also A. S. Eddington, *Stars and Atoms* (1927) and F. J. M. Stratton, *Modern Eclipse Problems* (Halley Lecture, 1927). J. N. Lockyer's early researches on the chromosphere are contained in *Contributions to Solar Physics* (1874) and *Chemistry of the Sun* (1887). Original records of eclipse observations on the chromosphere are given in the following fundamental memoirs:—*Phil. Trans. Roy. Soc.*, vol. 187A, 1896 (J. N. Lockyer, A. Fowler and W. Shackleton); *Mem. Roy. Astron. Soc.*, vol. 54 (appendices) (1901 and 1902, J. N. Lockyer; 1901 and 1903); J. Evershed, vol. 57 (appendix) (1906, F. W. Dyson); *Astrophys. Journ.*, vol. 38 (1913, S. A. Mitchell); *Mem. Roy. Astron. Soc.*, vol. 64 (1927, C. R. Davidson and F. J. M. Stratton). For the rotation of the chromosphere see W. S. Adams, *Astrophys. Journ.*, vol. 29 (1909). Saha's fundamental paper on ionization in the chromosphere occurs in *Phil. Mag.*, vol. 40 (1920). The mathematical theory of the equilibrium of the chromosphere is given in E. A. Milne's papers in *Monthly Notices R.A.S.*, vols. 84–87 (1924–27). See also *Monthly Notices*, vol. 87 (1927, S. R. Pike and P. A. Taylor). For recent views on the height of the chromosphere see correspondence in *Observatory*, vol. 48, 49 (1925, 1926: J. Evershed, S. A. Mitchell, E. A. Milne, A. A. Buss and G. Abetti).

(E. A. MI.)

CHRONAXIE, a term introduced by Louis Lapicque in 1909 to define the character of the stimulus which is required to excite various types of living tissue, particularly muscle and nerve. The most convenient form of stimulus is an electric current, since this can be made to excite (*i.e.*, to cause the tissue to display its characteristic activity) without doing any damage. It is found that a current must fulfil three conditions if it is to excite—(1) it must flow for more than a certain minimal duration; (2) the final strength must exceed a certain value; and (3) the rate of increase of the current from zero must exceed a definite velocity. The need for a minimal duration is shown by the fact that a current alternating at a million cycles a second is powerless to excite any tissue in the body; and the modern surgical technique of diathermy is based on this.

The curve relating minimal duration and minimal strength has the form shown in the figure, and as a first approximation it obeys the formula of Weiss, $i = a + \frac{b}{t}$, where i is the current, t its duration and a and b are constants. Lapicque has shown that curves of the same form are obtained from the most diverse

tissues, ranging from the human nerve, where the minimal duration is less than 0.001 sec., to the cells of a plant where it may be longer than 1 sec. Thus the character of the stimulus for a given tissue can be defined at once if we know the constants a and b for that tissue. The constant a (the "Rheobase") is given by the minimal current strength at long durations. The other constant b is the more important, for it determines the slope of the curve, it can be fixed by measuring the "Chronaxie," which is equal to $\frac{b}{a}$ and is the least duration required when the current strength is $2a$.

The true form of the curve differs somewhat from that given by Weiss's equation, and it has been used as a basis from which to deduce the mechanism of excitation. In Lapicque's hands the measurement of the Chronaxie has also been used to investigate the passage of the state of excitation from one tissue to another (*e.g.*, from nerve to muscle).

(E. D. A.)

FORM OF A STIMULATING CURRENT IN LIVING TISSUE

The curve shows the relation between the strength and the duration of the smallest current which will excite a living cell. The Chronaxie and the Rheobase are the two constants which define the curve

CHRONICLE. The historical works written in the middle ages are variously designated "histories," "annals," or "chronicles" (from Gr. *χρόνος*, time); it is difficult, however, to give an exact definition of each of these terms, since they do not correspond to determinate classes of writings. Perhaps the most reasonable

definition is that given by H. F. Delaborde at the École des Chartes, that chronicles are accounts of a universal character, while annals relate either to a locality, or to a religious community, or even to a whole people, but without attempting to treat of all periods or all peoples. The primitive type, he says, was furnished by Eusebius of Caesarea, who wrote (*c.* 303) a chronicle in Greek, which was soon translated into Latin and frequently recopied throughout the middle ages; it embraced the history of the world since the Creation. It is certain, however, that mediaeval authors or scribes were not conscious of any clear distinction between annals and chronicles; indeed, they often apparently employed the terms indiscriminately.

In any case, chronicles and annals (*q.v.*) have points of great similarity. Chronicles are accounts generally of an impersonal character, and often anonymous, composed of passages copied from sources which the chronicler is seldom at pains to indicate, and of personal recollections the veracity of which remains to be determined. Some of them are written with so little intelligence that the work of composition seems a mere piece of drudgery imposed on the clergy and monks by their superiors. To distinguish what is original from what is borrowed, to separate fact from falsehood, and to establish the value of each piece of evidence, is thus a difficult undertaking, and one which has exercised the sagacity of scholars, especially since the 17th century.

The Christian chronicles were first written in the two learned languages, Greek and Latin. At an early stage we have proof of the use of national languages, the most famous instances being the Anglo-Saxon Chronicle (*q.v.*), the most ancient form of which goes back to the 10th century, and the so-called Chronicle of Nestor, in Palaeo-Slavonic, written in the 11th and 12th centuries. In the 13th and 14th centuries the number of chronicles written in the vulgar tongue continued to increase more rapidly on the Continent than in England. From the 15th century, with the revived study of Greek and Roman literature, the traditional form of chronicles, as well as of annals, tended to be replaced by another based on the models of antiquity—that of the historical composition combining skilful arrangement with elegance of style. It was not, however, until the 17th century that the traditional form became practically extinct.

1903); H. Bloch, "Geschichte der deutschen Geschichtsschreibung im Mittelalter" in the *Handbuch* of G. von Below and F. Meinecke (Munich, 1903 seq.); Max Jansen, "Historiographie und Quellen der deutschen Geschichte bis 1500," in Alois Meister's *Grundriss* (Leipzig, 1906); and the Introduction (1904) to A. Molinier's *Les Sources de l'histoire de France*. (C. BEM.)

CHRONICLES, BOOKS OF, two Old Testament books of the Bible. The name is derived from *Chronicon*, first suggested by Jerome as a rendering of the title which they bear in the Hebrew Canon, viz. *Events of the Times*. (1 Chron. xxviii. 24; Esth. x. 2, etc.) The Greek translators divided the long book into two, and adopted the title *Παραλειπόμενα*, *Things omitted* (scil. in the other historical books).

Authorship and Date.—The book of Chronicles begins with Adam and ends abruptly in the middle of Cyrus's decree of restoration, which reappears complete at the beginning of Ezra. A closer examination of those parts of *Ezra* and *Nehemiah* which are not extracted from earlier documents or original memoirs leads to the conclusion that *Chronicles-Ezra-Nehemiah* was originally one work, displaying throughout the peculiarities of language and thought of a single editor, who, however, cannot be Ezra himself as tradition states. The style of the language, and also the position of the book in the Jewish Canon, stamp the book as one of the latest in the Old Testament. In 1 Chron. xxix. 7, which refers to the time of David, a sum of money is reckoned by *darics*, which certainly implies that the author wrote after this Persian coin had been long current in Judaea. In 1 Chron. iii. 19 sqq. the descendants of Zerubbabel seem to be reckoned to six generations (the Septuagint reads it so as to give as many as 11 generations), and this agrees with the suggestion that Hattush (v. 22), who belongs to the fourth generation from Zerubbabel, was a contemporary of Ezra (Ezra viii. 2). With this it accords that in *Nehemiah* five generations of high priests are enumerated from Joshua (xii., 10 seq.), and that the last name is that of Jaddua, who, according to Josephus, was a contemporary of Alexander the Great (333 B.C.). A date some time after 332 B.C. is now accepted by most modern critics. See *EZRA AND NEHEMIAH*.

Scope and Object.—The writer lived a considerable time after Ezra and stood entirely under the influence of the religious institutions of the new theocracy. This standpoint determined the nature of his interest in the early history of his people. The true importance of the history of Israel centred in the fact that this petty nation was the people of Yahweh, the spiritual God. The tragic interest which distinguishes its annals from the forgotten history of Moab or Damascus lies wholly in that contest which vindicated the reality of spiritual things and the supremacy of Yahweh's purpose, in the political ruin of the nation which was the faithless depository of these sacred truths. After the return from the Exile it was impossible to write the history of Israel's fortunes otherwise than in a spirit of religious pragmatism. But within the limits of the religious conception of the plan and purpose of the Hebrew history more than one point of view might be taken up. The book of Kings looks upon the history in the spirit of the prophets—in that spirit which is still echoed by Zech. i. 5 seq., but which had become extinct before the Chronicler wrote. The New Jerusalem of Ezra was organized as a municipality and a church, not as a nation. The centre of religious life was no longer the living prophetic word but the ordinances of the Pentateuch and the liturgical service of the sanctuary. The religious vocation of Israel was no longer national but ecclesiastical or municipal, and the historical continuity of the nation was vividly realized only within the walls of Jerusalem and the courts of the Temple, in the solemn assembly and stately ceremonial of a feast day. These influences naturally operated most strongly on those who were officially attached to the sanctuary. To a Levite, even more than to other Jews, the history of Israel meant above all things the history of Jerusalem, of the Temple, and of the Temple ordinances. Now the writer of Chronicles betrays on every page his essentially Levitical habit of mind. It even seems possible from a close attention to his descriptions of sacred ordinances to conclude that his special interests are those of a common Levite rather than a priest, and that of all Levitical

functions he is most partial to those of the singers, a member of whose guild he may have been. From the standpoint of the post-exilic age, the older delineation of the history of Israel, especially in the books of Samuel and Kings, could not but appear to be deficient in some directions, while in other respects its narrative seemed superfluous or open to misunderstanding, as for example by recording, and that without condemnation, things inconsistent with the later post-exilic law. The history of the ordinances of worship holds a very small place in the older record. Jerusalem and the Temple have not that central place in the book of Kings which they occupied in the minds of the Jewish community after the Exile. Large sections of the old history are devoted to the religion and politics of the ten tribes, which are altogether unintelligible and uninteresting when measured by a strictly Levitical standard; and in general the whole problems and struggles of the prophetic period turn on points which had ceased to be cardinal in the life of the New Jerusalem, which was no longer called to decide between the claims of the Word of Yahweh and the exigencies of political affairs and social customs, and which could not comprehend that men absorbed in deeper spiritual contests had no leisure for the niceties of Levitical legislation. Thus there seemed to be room for a new history, which should confine itself to matters still interesting to the theocracy of Zion, keeping Jerusalem and the Temple in the foreground, and developing the divine pragmatism of the history, not so much with reference to the prophetic word as to the fixed legislation of the Pentateuch, so that the whole narrative might be made to teach that the glory of Israel lies in the observance of the divine law and ritual.

Contents.—For the sake of systematic completeness the book begins with Adam, as is the custom with later Oriental writers. The early history is contracted into a series of tribal and priestly genealogies, which were doubtless by no means the least interesting part of the work at a time when every Israelite was concerned to prove the purity of his Hebrew descent (cf. Ezra ii. 59, 62). Commencing abruptly (after some Benjamite genealogies) with the death of Saul, the history becomes fuller and runs parallel with the books of Samuel and Kings. The limitations of the compiler's interest in past times appears in the omission, among other particulars, of David's reign in Hebron, of the disorders in his family, and the revolt of Absalom, of the circumstances of Solomon's accession, and of many details as to the wisdom and splendour of that sovereign, as well as of his fall into idolatry. In the later history the ten tribes are quite neglected ("Yahweh is not with Israel," 2 Chron. xxv. 7), and political affairs in Judah receive attention, not in proportion to their intrinsic importance, but according as they serve to exemplify God's help to the obedient and His chastisement of the rebellious. That the compiler is always unwilling to speak of the misfortunes of good rulers is not necessarily to be ascribed to a deliberate suppression of truth, but shows that the book was throughout composed not in purely historical interests, but with a view to inculcating practical lessons. The more important additions to the older narrative consist partly of statistical lists (1 Chron. xii.), partly of full details on points connected with the history of the sanctuary and the great feasts or the archaeology of the Levitical ministry (1 Chron. xiii., xv., xvi., xxii.-xxix.; 2 Chron. xxix.-xxx., etc.), and partly of narratives of victories and defeats, of sins and punishments, of obedience and its reward, which could be made to point a plain religious lesson in favour of faithful observance of the law (2 Chron. xiii., xiv. 9 sqq.; xx., xxi. 11 sqq., etc.). The minor variations of *Chronicles* from the books of Samuel and Kings are analogous in principle to the larger additions and omissions, so that the whole work has a consistent and well-marked character, presenting the history in quite a different perspective from that of the old narrative.

Value.—For a critical study of the book it is necessary to compare carefully *Chronicles* with the parallel narrative in *Samuel-Kings*. "A careful comparison of *Chronicles* with *Samuel and Kings* is a striking object lesson in ancient historical composition; it is an almost indispensable introduction to the criticism of the Pentateuch and the older historical works" (W. H. Bennett, *Chronicles*, p. 20 seq.). Where *Chronicles* directly con-

tradicts the earlier books there are few cases in which an impartial historical judgment will decide in favour of the later account, and in any point that touches difference of usage between its time and that of the old monarchy it is of no authority. A certain freedom of literary form was always allowed to ancient historians; and the typical speeches in Chronicles are of little value for the periods to which they relate, especially where they are inconsistent with the evidence from earlier writings. According to the ordinary laws of research, the book, being written at a time long posterior to the events it records, can have only secondary importance, although here and there valuable material has been preserved. It must be remembered that the earlier books contain only a portion of the material to which the compilers had access. Hence it may well happen that the additional details, which unfortunately cannot be checked, were ultimately derived from sources as reputable as those in the books of Samuel, Kings, etc. As examples may be cited Rehoboam's buildings, etc. (2 Chron. xi. 5-12, 18 *seq.*); Jeroboam's attack upon Abijah; (2 Chron. xiii., *cf.* 1 Kings xv. 7); the invasion of Zerah in Asa's reign (2 Chron. xiv.; *see* ASA); Jehoshaphat's wars and judicial measures (2 Chron. xvii. xx.; *see* 1 Kings xxii. 45); Jehoram's family (2 Chron. xxi. 2-4); relations between Jehoiada and Joash (2 Chron. xxiv. 3, 15 *seq.*); conflicts between Ephraim and Judah (2 Chron. xxv. 6-13); wars of Uzziah and Jotham (2 Chron. xxvi. *seq.*); events in the reign of Ahaz (2 Chron. xxviii. 8-15, 18 *seq.*); reforms of Hezekiah (2 Chron. xxix. *seq.*, *cf.* Jer. xxvi. 19); Manasseh's captivity, repentance, and buildings (2 Chron. xxxiii. 10-20; *see* 2 Kings xxi. and MANASSEH); the death of Josiah (2 Chron. xxxv. 20-25). In addition to this reference may be made to such tantalizing statements as those in 1 Chron. ii 23 (R.V.), iv. 39-41, v. 10, 18-22, vii. 21 *seq.*, viii. 13, xii. 15, examples of the kind of tradition, national and private, upon which writers could draw. Although in their present form the additional *narratives* are in the chronicler's style, it is not necessary to deny an older traditional element which may have been preserved in sources now lost to us.

BIBLIOGRAPHY.—Robertson Smith's famous article in the 9th ed. of the *Ency. Brit.* was modified by his later views in *Old Test. in the Jewish Church*, pp. 140-148. Later literature is summarized by Driver in his revision of Smith's article in *Ency. Bib.* and in his *Lit. of Old Test.*, by F. Brown in Hastings's *Dict. Bib.* and by Elmslie (in the Cambridge Bible). (W. R. S.; S. A. C.)

CHRONOGRAPH, an instrument for recording the passage of time; thus the name is applied to the stop-watch used for timing races, etc. Press a key and the index of the dial sets to zero; press again and the index starts to move at normal rate, say one revolution per 60 secs., by steps of one-fifth sec.; press a third time and the index stops, and the event is "timed" by reading the dial. Attention to the defects of this crude form of chronograph will show the necessity for the refinements described below. In the first place, by setting the start of the event at zero the timing instrument is detached from other clocks and therefore the absolute time of start and finish are lost; secondly, a watch or other time-piece cannot be trusted to move at a standard pace immediately after it is set in motion; thirdly, no means are provided for checking its going; fourthly, the step-by-step movement of the hand of a watch limits the precision of the reading to one whole step; fifthly, the observer must note the beginning of the event and simultaneously start his watch, and note the end, and simultaneously stop it—otherwise he will introduce an error. In some cases the first condition is of no importance; the others are always important.

The faults relating to the clock are met by a double device. An independent, well-made piece of clock-work moves a paper band at an approximately uniform rate; on this a standard clock, the rate and error of which can be found otherwise (*see* TIME, MEASUREMENT OF) impresses a mark every second or every two seconds; the "personal" error of the observer is eliminated by making the event itself impress a similar mark, which as a rule will fall between two of the seconds-marks of the clock, so that the event may be timed with any degree of precision by measuring the distances of its mark from the two adjacent seconds-marks. The exactness of the chronograph is limited by the

precision with which these requirements can be carried out in practice; this will be best shown by describing some standard forms.

The figures show the front and back view of a three-pen chronograph by H. Wetzer, Pfronten, Bavaria. A fillet of paper is wound at a regulated and approximately constant speed from a roll over a small bench, above which are three pens in light contact with

BY COURTESY OF H. WETZER

FIG. 1.—FRONT VIEW OF A CHRONOGRAPH. WHEN A SIGNAL PASSES, THREE PENS, MOVED INDEPENDENTLY OF ONE ANOTHER BY ELECTRO-MAGNETS, TRAIL ON A FILLET OF PAPER RELEASED BY CLOCKWORK

it, so that when nothing is happening the paper trails beneath them and they leave straight traces. Each pen is carried on an independent arm which is linked to the armature of a pair of electro-magnets. If a current passes in one of these magnets, the armature is depressed and the arm moves sharply backwards, indenting the trace in the manner shown in fig. 4 where several traces are given, taken from a six-pen chronograph, corresponding to different settings. Usually the standard clock governs the signals sent to one pair of magnets, say the third trace in this figure, so that the beginning of the indentations would correspond with its seconds. A taper scale, ruled on glass and laid across the paper, permits the time corresponding to any other mark on the paper to be read at sight to, say, one hundredth of a second. If a higher degree of subdivision is wanted, it is advisable to proceed by quite a different method, as described below. In other forms of chronograph the pens are replaced by needle points which prick the paper when the armature descends. The needle is carried in a rocking head so that as the paper moves on, the needle, after pricking the paper, trails until the armature is released again, so as not to retard the movement of the fillet. In other forms again the fillet of paper is replaced by a sheet wound upon a drum, which the clock-work causes to rotate once a minute, while a carriage containing the pens and magnets moves longitudinally beside it. The figure shows a pattern made by the Société Gènevoise. In this pattern the motion is derived from

a small electro-motor, and not from weight-driven clock-work.

The chronograph may be arranged so as to yield a print in plain figures of the time recorded. Three wheels, engraved with embossed figures showing minutes, seconds and hundredths of a second, are driven at a rate which is controlled so as to agree with the standard clock, and a fillet of paper, with an inking ribbon between, passes over them. When a signal passes that has to be recorded, electro-magnets cause three hammers to descend and print upon the paper the figures that are exposed below it. Fig. 3 shows a specimen trace.

In order to make this form of chronograph effective the clock-work for driving the type wheels requires rather special attention. The minutes (and seconds) wheels are readily controlled with sufficient accuracy, but the hundredths-of-a-second wheel should not be geared with the others, but should be run by an independent drive, accurately cut, with sensitive appliances for regulating as required its approximate rate. It is run normally slightly fast, and the control of the standard clock is exercised by a check once a second from the signal of the standard clock. It is desirable also to cause the standard clock itself to record at will its own signals, so that the amount by which the wheel is fast may be noted and applied as an index correction.

The electro-magnets for all these forms require to be fairly powerful, and are usually wound to about 20 ohms. resistance,

BY COURTESY OF HERR H. WETZER

FIG. 2.—A DIAGRAM SHOWING THE BACK VIEW OF A CHRONOGRAPH

being worked with batteries of 4 or 6 volts; the current that runs, 0.2 amp. or 0.3 amp., is therefore much greater than that of the signal from the standard clock which will never exceed about 10 milliamps. A relay must therefore be interposed. It will be noted that the time the relay takes to act, and the time between the commencement of its secondary current and the first movement of the armature, appear as a lag making the record of the chronograph slow on the clock signal. If, however, the error of the clock itself is determined with the same apparatus, the same lag will appear again, and will thus eliminate itself. This

supposes the lag to be constant. Experiments show that with the ordinary well-constructed commercial relay, if worked on currents greater than 5 or 6 milliamps, the lag is sensibly constant for the same setting of the relay and should not exceed a few thousandths of a second. See some tests of two Siemens Relays, published by the *Commission Géodésique Suisse*, 73rd. Sitting, 1927. (*Société-Helvétique des Sciences Naturelles*, Neuchatel,

FIG. 3.—TRACE FROM CHRONOGRAPH OF GENERAL TYPE EQUIPPED WITH 6 PENS

1927.) The part which is due to the electro-magnets of the chronograph may similarly be kept constant by attention to the accumulators that operate them.

As regards the event which has to be timed, any form of contact-maker, connected with its occurrence, and in series with a battery and one of the pairs of electro-magnets of the chronograph, will serve. It may be necessary to interpose a relay. The process may be illustrated by astronomical timing, which is one of the most refined forms, and is done as follows. A star in passage across the field of view of a transit instrument is held bisected by a spider thread, the carrier of which for this purpose travels along a screw shaft actuated by a terminal pair of hand drums. Connected with this shaft is a rotating contact maker. At each revolution a contact is made and is recorded on the chronograph, which thus obtains a record of the time when the star passed a number of fiducial positions in the field of view. Manipulation of the drums requires skill, and is sometimes replaced by an automatic drive, but in any case the observer is unaware when he is making a contact and therefore his bias or "personality" cannot enter in that way. Other events would require different arrangements, but the guiding principles would be the same.

It will be noticed that in all these forms of chronograph, except the printing chronograph, the timing of the mark recording the desired event is found by measuring its distance from two time marks, giving as a rule successive seconds. The accuracy therefore depends upon the uniformity of movement of the paper. The clock-work drive, with continuous motion, is liable to fluctuate more or less. If it does so smoothly, so that it moves the paper at the same rate for several successive seconds, its absolute rate of movement matters little and the measurement may be made at sight, with accuracy up to one-hundredth of a second,

FIG. 4.—DRUM CHRONOGRAPH MADE BY THE SOCIÉTÉ GÉNEVOISE, IN WHICH THE MOTION IS DERIVED FROM A SMALL ELECTRO-MOTOR

by the usual device of a taper scale, engraved on glass, showing seconds of different lengths within the ranges that are likely to occur, and divided into tenths. Sliding the scale across the marked paper, the seconds-marks are fitted to the boundary lines of the scale, and the interpolation of the time of the event in tenths and estimated hundredths is read off. For making this operation accurately the character of the mark on the paper is important. Perhaps the best form in point of accuracy is the circular perforation made by a needle, in place of an ink mark by a pen, but it is trying to the sight unless the illumination is specially arranged, and it is rather easily effaced.

In all cases the signal of the standard clock is so arranged as to indicate the beginning of the minutes, either by omitting a signal or by duplicating it. If it is of importance to feed the

paper quite regularly, the device called the phonic wheel may be employed. Clock-work for the drive is replaced by a small electric-motor, which is driven synchronously with a maintained tuning-fork. A fork of 50 periods per second is found suitable. The system gets rid of substantial fluctuations in the feed, but it is far from ideal, for a tuning-fork maintained in the usual way by means of a small electro-magnet excited by a contact made

FIG. 5.—SIPHON RECORDER MADE BY H. TINSLEY FOR THE ROYAL OBSERVATORY, EDINBURGH

The signal passes through the coil, which hangs between the poles of a permanent magnet, and carries a siphon pen leading from an inkwell to the paper fillet. A second siphon, actuated by a pair of electro-magnets, gives independent signals

at the extremity of its excursion cannot be relied upon to keep closely a set period as when free.

The introduction of relays in the system, in order to replace the weak signal from the standard clock, or that given by the event to be recorded, may be avoided by using the siphon recorder. The illustration shows a recorder manufactured by H. Tinsley and Co. Between the poles of a strong permanent magnet a coil is suspended through which the weak signal current is made to pass. When a current passes, the coil is deflected. Attached to the coil is the "siphon," which usually consists of a very fine glass tube, bent to an appropriate shape and conveying ink from a well to the fillet of paper which travels at a lower level. A very small current may be made to record directly on this apparatus. Both the signals, from the clock and from the events for record, may often be made to pass through the same coil. The movement of the paper in the figure shown is controlled by a phonic wheel.

None of these devices is suitable for obtaining records of intervals definitely less than a hundredth of a second, or of timing events to a like precision. Where a pivoted arm is started from rest by means of an electro-magnet, or is used to make a contact, it is liable to vary accidentally to an amount of at least .003 seconds, under the best circumstances. Further a record written or pricked upon a fillet of paper does not yield more information if magnified. The proper resource is an adaptation of the oscillograph, which can be used for exploring accurately what passes in the minutest intervals of time, almost without limit. The principle is simply that described above in connection with the siphon recorder—in other words, the principle of the Einthoven galvanometer, in which a feeble current is passed around a coil or loop which is suspended in a strong magnetic field. The field deflects the coil when a current passes. By suspending the coil with an appropriate reaction to return to its normal position, and by changing the magnetic field, the deflection may be made of any suitable amount, and to take place in a given period of time which may be made very short. With air damping the motion is perfectly dead beat. Further, whether the signal current is constant or not, the interval of time between its onset and the final set of the coil is strictly constant, so that the lag introduced is the same in every case, and the variation of the actuating current is recorded without distortion. A small light mirror mounted on the coil or loop shows the deflection by reflecting a fixed spot of light, or alternatively the current may pass along a single wire or thread and the deflection of this thread by the magnetic field may be projected optically. The pro-

jection is recorded photographically. Any degree of rapidity of change may be met by suitable movement of the recording film. For speeds that are not too great, and for prolonged records, a cinema camera with its roll of film is driven by an electric motor. For great speeds a plate may be allowed to fall between guides past the exposure window. Feebleness of signal current is met by intensifying the magnetic field, and again the photographic record may be magnified in a microscope. By this device the details of the oscillating discharge of a condenser may be made evident, or, on the other hand, the feeblest physiological currents may be recorded. Clearly it only requires adaptation to the problem to make it an instrument practically perfect for pure time recording.

It has thus been applied in "sound-ranging" in artillery, which consists in the location of the position of a gun by noting the difference of time of arrival of the sound at three known points. A special form of detector permits the use of very small currents; the oscillograph or galvanometer is used in the form where the signals for record, whether event or clock, pass through single threads, the movements of which are projected side by side and photographed on a moving strip. In this way the true times of arrival of the sound of all the guns of a battery, side by side and fired by intention as nearly as possible at the same moment, are sorted out from one another with perfect distinctness.

For most purposes and for continuous work high speed records are too voluminous and too costly. But the method of the oscillograph has been applied regularly at the Royal Observatory, Edinburgh, and incidentally elsewhere, to the study of chronometric problems. No clock, for example, has so far been constructed which will hold the same daily rate without change, even when kept at constant pressure and at constant temperature. Under what circumstances and by what amounts does it change? To answer this question it is essential to dispense with any mechanical relay and have an instrument that can record as small a current and as short an interval of time as we please; further it is essential to analyse the actual signal, make or break, to identify the "chattering" of a contact piece upon its bed and to notice the effects of self-inductance or a by-pass in the circuit. All this the oscillograph can readily do. The loop form of detector, with a mirror spanning the loop, a slit for illumination and a cinema camera armed with a cylindrical lens to concentrate the light, serves very well. It only remains to meet the inevitable variation of the movement of the film between two signals from the clocks. This can be done by interrupting the light from the slit by means of a tongue, vibrating, say, in tenths of a second and thus impressing on the film fiducial marks for measurement, which are close enough together to permit the motion to be treated as uniform from one to the next. For experiments lasting a minute or less such a tongue should be left completely free without maintenance of any sort. By means of this appliance the clock time of the occurrence of any event may be recorded to one-thousandth of a second, or more precisely if desired. This is a very different problem from measuring a very brief interval without regard to the absolute times when it begins and ends.

These are the standard methods of dealing with the registration of time. A great variety of problems involve one or other of them, and some require very special appliances, but these are special to the problem and not to chronography. First should be mentioned the determination of the velocity of light. Light is propagated at a speed of 186,000 miles (300,000 km.) per second, and the speed is measured by the time of passage to and from across a measured base line. The exceedingly short interval of time involved is not recorded but is merely determined in terms of the period of a standardized tuning-fork. (See the articles "Velocity of Light" and "Measurement of Time" by A. A. Michelson, in the *Astrophysical Journal* of the University of Chicago, Vol. 65 [1927] p. 1.) Problems of the flight of projectiles resolve themselves into the question of causing the projectile to make suitable signals at definite points, which is most simply done by making it sever wires conveying electric currents. If the question is merely to ascertain the speed of a small projectile, the chronograph is not involved, as the speed may be ascertained by firing

the projectile into a massive wooden block mounted as a pendulum, and then measuring the momentum conveyed to the block by noting the angle to which it swings. (R. A. S.)

CHRONOLOGY, a time-scale, a system of reckoning time massively. In testimony of the social memory and of the classification and exploitation of social experiences embedded therein mankind has learnt to recognize the orderly recurrence of natural phenomena and to base thereon his calendar (*q.v.*).

Astronomy.—Every science has now its chronology. The astronomer reminds us that "looked at in the astronomical time-scale, humanity is at the very beginning of its existence—a new born babe, with all the unexplored potentialities of babyhood" (J. H. Jeans in *Nature*, Supplement, March 1928); so that the chronology of the astronomer "uses a clock which does not tick seconds but years: its minutes are the lives of men." It tells us "that light travelling 186,000 m. a second, takes about 140 million years to come to us from the most remote objects visible in the biggest telescope on earth" (*ibid.*).

Geology.—We turn now from chronology of this vastness—to the chronology of this habitable globe, to the time scale of geology (*q.v.*) which is based for its larger divisions on the record of physical events, displaying ice-ages, periods of mountain building, of tectonic activity. By the aid of palaeontology, smaller divisions are established: yet here again we deal with vast figures.

Anthropology.—The earth (*q.v.*) must be 2,000 million years old and man from the best evidence now available, has existed thereon for something like 300,000 years.* Where then—with a 12 in. measure as our scale—shall we place the beginnings of our race? Each division of an inch stands for 160,000,000 years, so we divide the last of our inches of our scale by 50 and there place the first appearance of man. Where shall we place the Piltdown man (*see* MAN), or Heidelberg man? Divide one fiftieth of an inch into tenths and mark the fifth of these divisions as the age of Piltdown man.

Archaeology.—Where shall we put the beginnings of the Neolithic age, when agriculture, domestication, settled life, metal-lurgy all have their beginning? It is so near us that we cannot mark it successfully. We can no longer use our big scale. We must change our scale and take a scale of 12 in. to represent the 300,000 years of man's existence. Each inch stands for 25,000 years and we must place the dawn of what is essential to modern life about halfway in the last or 12th of our inches. Ur and its treasures go to 3500 B.C. or 5,000 years ago and are one-fifth of an inch from to-day. Egypt is but a century or two later. The Indus civilization comes next and then that of China. The archaic culture of Central America is 3,000 years old, but by then great empires in the East had waxed and waned and disappeared. Egypt was then old Egypt; and the Greeks like Herodotus were as children in cultural growth.

History.—Again we must change our scale. If we take the Neolithic age as 12,000 years ago, as a basal point (ignoring thereby all the Palaeolithic and Eolithic periods), each inch stands for 1,000 years. The discovery of the New World called America comes half way in the last inch upon this scale and there is so much to cram into the last tenth of the last inch that we are almost tempted to augment our scale once more.

Dynastic Reckoning.—When we come to the great civilizations of antiquity in the valleys of the Euphrates, the Tigris and the Nile or in China, we find established the method of chronological computation by reckoning dynasties of rulers. Social continuity finds its expression and its measure in this development of social organization. But dynasties are human, and disappear. Within the framework of historical chronology we may at will establish periods based on the varying phases and variable elements of human culture. The founders of great religions are remembered in the chronologies of their followers. There are great periods in art, in literature, in science, not inaptly recorded and recollected and concentrated by the names of great individuals. It is still true that the world forgets. The record of their existence and often their deeds are being revealed to us by archaeology (*q.v.*) so that we seem to know more of them and

*Sir A. Keith places the Piltdown skull as of a million years ago.

their fore-runners than they even knew themselves. Yet in their flourishing days, which by scale of time are so near to us and by scale of culture seem so different, there was behind them a long past, unheeded, ignored, yet potent in their lives as their achievements are still potent in and even essential to our lives. (*See* CALENDAR.)

CHINESE

From the time of the emperor Yao, upwards of 2,000 years B.C., the Chinese had two different years—a civil year, regulated by the moon, and an astronomical year, which was solar. The civil year consisted in general of twelve months or lunations, but occasionally a thirteenth was added to preserve its correspondence with the solar year. Even at that early period the solar or astronomical year consisted of 365½ days, like our Julian year, arranged in the same manner, a day being intercalated every fourth year. The civil day begins at midnight and ends at the midnight following.

Since the accession of the emperors of the Han dynasty, 206 B.C., the civil year of the Chinese has begun with the first day of that moon in the course of which the sun enters into the sign of the zodiac which corresponds with our sign Pisces. From the same period also they have employed, in the adjustment of their solar and lunar years, a period of nineteen years, twelve of which are common, containing twelve lunations each, and the remaining seven intercalary, containing thirteen lunations. It is not, however, precisely known how they distributed their months of thirty and twenty-nine days, or, as they termed them, great and small moons.

The Chinese divide the time of a complete revolution of the sun with regard to the solstitial points into twelve equal portions, each corresponding to thirty days, ten hours, thirty minutes. Each of these periods, which is denominated a *tsieh*, is subdivided into two equal portions called *chung-ki* and *tsie-ki*, the *chung-ki* denoting the first half of the *tsieh*, and the *tsie-ki* the latter half. The *tsieh* are thus strictly portions of solar time, and give their name to the lunar months, each month or lunation having the name of the *chung-ki* or sign at which the sun arrives during that month. As the *tsieh* is longer than a synodic revolution of the moon, the sun cannot arrive twice at a *chung-ki* during the same lunation; and as there are only twelve *tsieh*, the year can contain only twelve months having different names. It must happen sometimes that in the course of a lunation the sun enters into no new sign; in this case the month is intercalary, and is called by the same name as the preceding month, with the addition of the word *jun* (intercalary). (X.)

EGYPTIAN

The chronology of Ancient Egypt has been ascertained by means of the various statements of classical authors, by regnal years and the numerous other indications on the monuments, by the results of close archaeological study, and the ascertaining of certain fixed astronomical data, checked by comparison with the known chronology of the ancient nations which afford synchronisms with events in Egyptian history. The Egyptians never possessed a regular era, as the Assyrians did with their list of *limmu* officials (*see* ASSYRIA). Only once is an era mentioned, in the description of Rameses II., mentioning the 400th year of the Hyksos king (?) Nubti which fell in his reign. We only hear of such and such a regnal year of a king or, in early days, of the years of certain fiscal numberings. Regular regnal annals are very rarely preserved, though we have fragments of them in the Old Kingdom in the *Palermo Stone*, and there is of course the famous *Turin Papyrus of Kings*, which is invaluable even in its mutilated condition. Under the 12th and 22nd Dynasties the custom of the association of fathers and sons on the throne enables us to check the chronology of the overlapping years of those periods (as when the 10th year of one king is stated to be the first of another), and so reconstitute the length of the dynasty with some accuracy. The use of synchronisms with Mesopotamian history is evident when we see that the reign of Rameses II. is contemporary with that (of certain date) of Shalmaneser I. of Assyria (*c.* 1250 B.C.), a *datura* with which other synchronisms agree. And dates fixed astronomically are of great importance. The Egyptian did not note eclipses

as the Mesopotamian did, so that we have not this evidence. But we have the observations of the heliacal risings of the star Sothis (Sirius), which have supplied us with certain fixed dates which are of great importance, the more so as they agree with the results obtained from synchronisms. The Egyptian calendar was regulated by the observations of the heliacal risings of Sirius, which were supposed to take place on the first day of the first month of the year. But as an additional leap year day was not intercalated every four years in addition to the year of 360-5 "epagomenal" days, the months gradually lost all relation to the seasons, and it was not till 1,460 years after the last accurate coincidence that the heliacal rising of Sirius again took place accurately on the first day of the first month. When it did the event was celebrated as the beginning of a new "Sothic cycle." We know that a new cycle began either in 139 or in 143 A.D. An Alexandrian mathematician calls the initial year of the preceding cycle (1321 or 1317 B.C.) the "epoch of Menophres." The "throne-name" of Rameses I., who began to reign, it is known from the synchronism of Rameses II. with Shalmaneser III., about 1320 B.C., is Menpehtira or more shortly Menpehrah (a form that constantly occurs), which is obviously "Menophres." Now it would appear from contemporary evidence that Sothis rose heliacally on the first day of the month Pharmouthi in the seventh year of Senusret III., of the 12th Dynasty; so that it would seem easy to calculate that the seventh year of that king should be 1876 or 1872 B.C. (although another computer [Nicklin] has arrived at the date 1924 B.C. for the same year), on the assumption that this king reigned during the immediately preceding cycle which began in 2781 or 2778 B.C. Here, since synchronisms fail us, our knowledge of the historical development of Egyptian civilization and art comes to our aid to assure us that this must have been so, in spite of the fact that it is very difficult to square the lengthy list of kings given us by the Egyptians themselves with so short an interval as the two hundred years only which, if this conclusion is right, can have elapsed between the end of the 12th Dynasty and the beginning of the 18th. If it is right, the 12th Dynasty must have ended about 1788 B.C., and we know that the 18th cannot have begun later than 1580, from our full knowledge of the length of the reigns of that dynasty, confirmed by records of certain new-moon festivals at the time, as well as by synchronisms. So short is this period that Prof. Sir Flinders Petrie has preferred the view that Senusret and the 12th Dynasty really belong to the preceding cycle, and so go back to the fourth millennium B.C. This view however goes clearly against our archaeological knowledge. The resemblances between the culture of the early 18th Dynasty and the 12th are enough to forbid us to suppose that 1600 years elapsed between them, an epoch as long as that which separates Augustus from Queen Elizabeth. And our knowledge of the development of Minoan civilization (see *AEGEAN CIVILIZATION*) confirms this prohibition. The 12th Dynasty was contemporary with the Second Middle Minoan period; the early 18th with the First Late Minoan period. No student of Minoan archaeology could admit that these two Cretan epochs were separated by more than two or three centuries; 16 is impossible. Yet the fact remains that only two centuries or at the most three between the 12th and the 18th Dynasties are rather hard to accept. Four would seem more probable; and so it remains a moot question whether or not something has happened, some mistake in the observation of the star, or some unrecorded modification of the calendar, which would invalidate the modern calculation of the distance of time between Senusret and Rameses I. If, however, it is maintained that no such mistake is possible, then we must accept 1788 as the latest date of the end of the 12th Dynasty, 1861 B.C., as the earliest. The length of the dynasty we know from its recorded reigns to have been 212 years, so that it began about 2000 B.C. or about a century earlier, unless we choose to allow a little more time for a possible error, and suppose a date for it of c. 2212-2000 B.C. Further back we reach a state of great uncertainty. There are no synchronisms and no Sothic records to help us. The length of time between the beginning of the 12th Dynasty and the end of the 6th is unknown, but it cannot have been longer than two or three centuries. The Turin papyrus comes to our help with the statement that 955 years elapsed between the

beginning of the 1st Dynasty and the end of the 8th, a statement that agrees with historical and archaeological probability, and if we reckon the latter at about 2400 B.C. we reach 3350 as that of "Menes," the conflated founder of the kingdom (=the historical kings "Scorpion," Narmerza, and "Aha") (see *EGYPT: History; Art*). But Prof. Meyer now takes c. 3200 B.C. as the date of "Menes," assuming, as we have not, that the Sothic date of Senusret III. is incontrovertible. We have assumed 2212 as the beginning of the 12th Dynasty, and 2370 as that of the beginning of the 11th. The 8th may well have been contemporary with the 9th and 10th (Herakleopolites) and have lasted until c. 2400. If the "Kahun" date is correct, as Meyer assumes, and the end of the 8th dynasty is brought down to 2300, the Sothic cycle that began in 2781 or 2778 B.C. will then have fallen about the time of the 3rd Dynasty. If 2400 is taken as the date it will have fallen as late as the 5th. In either case, the yet earlier cycle-era in 4241 or 4238 B.C. will belong well before the beginning of the kingdom. And it has been supposed that the calendar must have been invented at that time, because the calendar was known before the 4th Dynasty. But the invention of a calendar presupposes a settled state and civilization, not the undeveloped culture of the predynastic period, though we do not know that there did not exist in Lower Egypt before the unification a political state where culture was sufficiently developed for such an invention to be made, and there have been considered to exist indications of the existence of such a state. Still, eight centuries between the invention and the unification under Menes is a very long time for such a hypothetical civilization to have endured apart from the fact that such an invention as a calendar must have occurred at the end of its development rather than its beginning; and recently a suggestion has been made by Dr. Scharff that revolutionizes our ideas on this point. This is that since the older date is so improbable the invention of the calendar in reality took place in 2781-2778 B.C., and since it was known before the time of the 4th Dynasty, this dynasty must in reality be later than that date, so that this Sothic cycle probably began about the time of the 3rd Dynasty. And it is significant that it is precisely in the time of the 3rd Dynasty, in the reign of king Zoser, that the great development of Egyptian culture took place that is ascribed to the inspiration of that king's minister, Imhotep, who was later deified as the patron of art and learning, including medicine, architecture, astronomy and science generally. It is then surmised that the calendar was invented by Imhotep or in his time, and that therefore the date 2781-2778 falls in the reign of Zoser. Now if this new surmise is correct, the 1st Dynasty will have begun rather later than 3200 B.C., and then the end of the 8th Dynasty will certainly fall about 2300. But in this case we shall have to assume the astronomically calculated "Kahun" date of Senusret III. to be unquestionably correct, as Meyer does, and must accept two centuries only between the 12th Dynasty and the 18th, in spite of the long Turin list of kings of this period, who then must have been mostly very ephemeral rulers. In any case the ancient list-compilers were evidently as much at sea in the two "intermediate" periods (6th-12th and 12th-18th Dynasties), as we are, for they suffered from absence of reliable material just as we do.

In later days, after the time of Rameses II., we have various data to help us. The date of Sheshonk (Shishak), the contemporary of Rehoboam and founder of the 22nd Dynasty, is fixed to c. 930 B.C. by Assyrian and biblical evidence, and for the Ethiopian kings, Shabak, Taharka and the rest, we have the fixed synchronisms with Assyrian kings whose dates are fixed by the *limmu*-lists. From the time of Psammetichus I., the founder of the 26th Dynasty, Babylonian and Greek authorities assist us, and his date is definitely known to be 663 (651 independent of Assyria)-609 B.C. After him we are dealing with the known facts of general ancient history as reported by the classical historians.

BABYLONIAN AND ASSYRIAN

Evidence of Babylonian documents, from 330 B.C. onwards, dated by kings' regnal years has settled many points in relation to the chronology of late as well as of early periods, though this evidence has been much discussed and often wrongly represented. It is now fairly clear that the era of the Arsacid dynasty was reckoned from 1st Nisan, 246, and that apparent divergences from this reckoning depend on ancient scribal errors or modern errors of interpretation. The Seleucid era was reckoned from 1st Nisan 311. There was no difference between "civil" and "religious" reckoning, as has sometimes been maintained. The reckoning of the Seleucid era from 311 B.C. must have been introduced in or before 305 B.C.; the years before that were actually spent by the Babylonians in a state of confusion as to dating which was introduced with the advent of Alexander the Great. The confusion was due in part to the use of two systems; in one reckoning, the year-dates according to the Macedonians was used, in another a dating strictly true of Babylon only, but this will not explain every case. The effect of this may be seen from the following list:—

| Year. | King. | Numbering. | |
|---------|-------------------------------|------------|-----|
| | | (a) | (b) |
| 330-329 | Alexander the Great | 7th | 1st |
| 323-322 | Philip Arrhidaeus | 2nd | 1st |
| 317-316 | Alexander IV. | .. | 1st |
| 316-315 | Antigonos | 1st | 2nd |

The exact method of dating between 311 and 305 is not certain; a broken document renders it possible that 311 was called "the seventh year of Alexander and Seleucus," i.e., that Seleucus associated his name with the king's for the first time, and that would account for the Babylonian reckoning of the Seleucid era. It should be noted that from the advent of Alexander the year reckoning commenced immediately from the accession of the king.

From 626 B.C.—331 B.C.—The ordinary Babylonian reckoning of regnal years, always observed before the Macedonian invasion, was from the 1st Nisan after a king's accession; months or days prior to Nisan were reckoned "beginning of kingship." There are two sources for the chronology of the New Babylonian and Persian empires, the canon of the Greek historian Ptolemy, and the reckoning which can be traced almost month by month and day by day; the tablets give names of rebels against the Persian kings otherwise unknown, and allow of more accuracy in dating, e.g., the coregency of Cambyses to the first year only of his father's reign.

| <i>New Babylonian Empire.</i> | Accession. | First full year. |
|--|------------|------------------|
| Nabopolassar | 626 | 625 |
| Nebuchadrezzar II. | 605 | 604 |
| Evil-Merodach | 562 | 561 |
| Neriglissar | 560 | 559 |
| Labashi-Marduk | 556 | .. |
| Nabu-na'id | .. | 555 |
| <i>Persian Empire.</i> | | |
| Cyrus | 539 | 538 |
| Cambyses | .. | 529 |
| "Smerdis," Nebuchadrezzar III. | .. | 522 |
| Darius I. | 522 | 521 |
| Xerxes I. | 486 | 485 |
| Artaxerxes I. | 465 | 464 |
| Darius II. | .. | 423 |
| Artaxerxes II. | .. | 404 |
| Artaxerxes III. (Ochus) | .. | 358 |
| Arses | .. | 337 |
| Darius III. | .. | 335 |

Between 648 and 626 B.C.—The dating of the New Babylonian empire secures the long uncertain dating of the fall of Nineveh; a chronicle, dating by the regnal years of Nabopolassar,

places that event in 612 B.C. The period from 648 to 626, the accession year of Nabopolassar, is still very obscure; the statements of Ptolemy's canon cannot exactly accord with the facts. Dating by Sin-sharishkun, the last king of Assyria up to the 7th year has been found at Sippar; since this year must at latest be 616, his first full year must at latest be 622. A certain Sin-shum-lishir, intervened between Ashur-etil-ilani, who reigned at least four years, and Sin-sharishkun, so that reckoning by Ashur-etil-ilani commenced in 627 at latest. Between 648 and 626 documents were dated by Kandalanu, the Kineladan of Ptolemy's canon; that this was a name assumed by Ashurbanipal as king of Babylon is doubtful, as there are good grounds for assuming that cuneiform scribes distinguished between the two. But since a building inscription dating from Ashurbanipal's 30th year has been found in Babylon, i.e., 639 B.C., the Assyrian must have claimed the kingship also.

From 911-648 B.C.—Assyrian chronology depends on lists of eponymous officials called *limmu*, by whom years were dated. These lists were drawn up in two ways; the first class consists of simple lists of names, the second gives in a column opposite the name an entry concerning the events of the year. An entry opposite the name Pur-Sagale reads, "Governor of Gozan. Revolt in the city of Ashur. In Siwan there was an eclipse of the sun," and this eclipse has been astronomically fixed as having taken place on June 15, 763 B.C. This fixes the years of all *limmu*s in the continuous list which reaches from 890-648. There are discrepant versions of these *limmu* lists which affect the reigns of Adad-nirari III. and Shalmaneser III.; these kings are allowed 29 or 28 and 35 or 34 eponyms to their reign. The weight of authority seems to lie with the lower numbers, but the question is not definitely settled; otherwise the Assyrian chronology of the period is fixed.

The Babylonian chronology of the time is less certain. Ptolemy's canon and cuneiform documents give the regnal years from Nabonassar's first year, 747 B.C. The belief that some kind of era commenced then is baseless; it was chosen by Ptolemy for some accidental reason, perhaps because that was the first fixed point that was known to him, but not for any scientific reason. Before Nabonassar, the continuous king-list is now known to have included between Shamash-mudammig, who was reigning about 910 B.C., and Nabonassar 16 names, an average of about 10 years apiece, but the exact lengths of reigns cannot yet be ascertained.

| <i>Babylonia</i> | | <i>Assyria</i> |
|---|---------|-------------------------------------|
| Shamash-mudammig, abt. | 910 | Adad-nirari II. 911-889 |
| Nabu-shum-ukin | .. | Tukulti-Enurta II. 889-884 |
| Nabu-apal-iddin | 7-851 | Ashurnasirpal II. 884-859 |
| Marduk-bel-usate | 851-850 | Shalmaneser III. 859-824 |
| Marduk-zakir-shum | 850-839 | |
| Marduk-balatsu-iqbi | 7-811 | |
| Bau-akh-iddin | 810 | Shamshi-Adad V. 824-812 |
| (Five names missing including Adad-shum-ibni) | | Adad-nirari III. 811-782 |
| Marduk-bel-zeri | .. | |
| Marduk-apal-usur | .. | Shalmaneser IV. 782-772 |
| Eriba-Marduk | .. | Ashur-dan III. 772-754 |
| Nabu-shum-ukin | .. | Ashur-nirari V. 754-745 |
| Nabonassar | 747-732 | Tiglathpileser III. 745-727 |
| Nabu-nadin-zer | 733-732 | |
| Nabu-shum-ukin | 732 | |
| Ukin-zer | 731 | |
| Pulu (-T.-P.III.) | 731-727 | Shalmaneser V. 726-722 |
| Ululai | 726-722 | Sargon II. 722-705 |
| Merodachbaladan II. | 721-710 | |
| Sargon | 709-705 | Sennacherib 705-681 |
| Sennacherib | 705-703 | |
| Merodachbaladan III. | 703-702 | |
| Bel-ibni | 702-700 | |
| Ashur-nadin-shum | 699-694 | |
| Nergal-ushezib | 693-692 | |
| Mushezib-Marduk | 692-689 | |
| Sennacherib | 688-681 | |
| Esarhaddon | 680-669 | Esarhaddon 680-669 |
| Shamash-shum-ukin | 668-648 | |
| Kandalanu | 647-626 | Ashurbanipal 668-638 (?) |

From About 1380-911 B.C.—There are broken *limmu* lists which once gave the eponymous officials from about 1200 B.C.; in their present state they give a framework for the Assyrian kings

from about 1068-911, the margin of error within which is not more than ten years. Complete king-lists for Assyria being now obtained from broken documents, approximate dates for the kings of the 13th century can be based on intervals sometimes mentioned between them and later kings. The approximate date of Ashur-uballit can be determined from his correspondence with Akhnaton, the Pharaoh of Egypt, with a marginal error of ten years, as about 1380.

Babylonian chronology depends upon the cases where the number of years are known, and on synchronisms with the Assyrian kings. The result can only be an approximation with a margin of error perhaps exceeding a decade. The arrangement is then roughly:—

| <i>Babylonia</i> | <i>Assyria</i> |
|---------------------------------|----------------------------------|
| Burnaburiash | Ashur-uballit . . . 1380-1335 |
| Karindash | |
| Kadashman-kharbe | |
| Shuzigash | |
| Kurigalzu III. (23 years) | Enlil-nirari . . . 1335- |
| | Arik-den-ili . . . -1311 |
| Nazimaruttash (26 years) | Adad-nirari I. . . 1310-1280 |
| Kadashman-turgu (17 years) | Shalmaneser I. . . 1280-1250 |
| Kadashman-Enlil (6 years) | |
| Kudur-Enlil (9 years) | |
| Shagarakti-shuriash (13 years) | Tukulti-Enurta I. . . 1250-1216 |
| Kashtiliash (8 years) | |
| Enlil-nadin-shum (1½ years) | |
| Kadashman-Kharbe (1½ years) | |
| Adad-shum-iddin (6 years) | |
| Adad-shum-nasir (30 years) | Ashur-nadin-apal . . . 1215-1212 |
| | Ashur-nirari III. . . 1211-1206 |
| | Enlil-kudur-usur . . . 1205-1201 |
| Meli-shipak (15 years) | Enurta-apal-ekur . . . 1200-1188 |
| Merodachbaladan I. (13 years) | Ashur-dan I. . . 1187-1150 |
| Ilbaba-shum-iddin (6 years) | |
| Enlil-nadin-akhekhe (3 years) | |
| Marduk-shapik-zeri (17 years) | |
| Enurta-nadin-shum (6 years) | |
| Nebuchadrezzar I. | Enurta-tukulti-Ashur |
| | Mutakkil-Nusku |
| Enlil-nadin-apal | Ashur-resh-ishi I. . . ?-1099 |
| Marduk-nadin-akhekhe | Tiglathpileser I. . . 1098-1068 |
| Itti-Marduk-balatu | Enurta-apal-ekur II. . . 1067- |
| Marduk-shapik-zer-mati | Ashur-bel-kala |
| Adad-apal-iddin (22 years) | Eriba-Adad II. |

Before 1380 B.C.—All earlier chronology must be subject to considerable margin of error. It depends on (1) Babylonian king-lists which give the number of regnal years; in many instances, where these figures can be checked by other sources, they are proved unreliable; (2) statements of Assyrian kings about their predecessors; the figures given are sometimes round numbers, and are never absolutely reliable; (3) dead reckoning on the basis of generations, coupled with the use of the rare synchronisms known between the two countries.

The Babylonian king-list allows 36 kings, and 576 years 9 months for the period during which the country was ruled by Kassite kings. Enlil-nadin-akhekhe, the last of the dynasty, succeeded to the throne in the time of Ashur-dan I., roughly about 1170, within a decade, and ruled three years: this would place Gandash, the first king, about 1743-42, but an increased margin of error must be allowed owing to the inaccuracy of the list. The 13th Kassite king, Ulam-Buriash, may have ruled about 1530-20; he occupied the Sea-land, the marshes at the head of the Persian gulf, when the last independent king of the Sea-land fled to Elam. This Sea-land dynasty numbered, according to variant accounts, 11 or 12 kings, who ruled for the long period of 368 years, which

would place Iluma-ilum, the first king, about 1900 B.C., if the last king fled just before 1530. But Iluma-ilum can be proved by various documents to be a contemporary of Samsu-iluna and Abi-esu', kings of the 1st dynasty of Babylon. Iluma-ilum is said to have reigned 60 years, and Samsu-iluna and Abi-esu' reigned respectively 38 and 28; it is not probable that Samsu-iluna began to reign before Iluma-ilum, and if he be assigned a date about 1900-1863, the end of the 1st dynasty is brought to about 1746, almost immediately before the accession of the first Kassite king. This cross-reckoning is satisfactory in itself and supported by the Assyrian king-list. There were 42 kings between Ilushuma, an early governor of Ashur, and Ashur-uballit, about 1380. According to kings' statements Ilushuma lived about 2000 B.C., and this accords roughly with other statements about his son. It is certain from an entry in a chronicle that Ilushuma carried out some military enterprise in Babylonia in the time of Sumu-abu, the first king of the 1st dynasty. If the 1st dynasty ended about 1746-45, the first king dated about 2045-44 to 2032-31. This would accord with the Assyrian statements.

Some modern authorities hold that a fixed dating, not based on the king-lists, can be secured from tablets dealing with observations of Venus. From an entry for the sixth year of Ammizaduga they calculate certain astronomical possibilities, and check the date obtained—one out of four or five possible—by calculations as to the probable period of the date-harvest. Arguing on these lines they hold the sixth year of Ammizaduga to be 1916-15, which would place the commencement of the 1st dynasty in 2170, its close in 1871; another, arguing on the same lines, would date these events 2049-1750. The former, if correct, will necessitate the abandonment of a great deal of Babylonian historical writing as worthless; the question is at present open, and scholars differ by some 120 to 130 years for this period.

Accepting the dating 2045-1745, admittedly open to a margin of error, for the 1st dynasty as fairly accurate, the date lists for the kings' reigns provide an accurate scheme which correct the king-lists in many places. These date-lists arose from the custom of naming a year by some event; in some cases the event was one of religious importance, and may actually have taken place in the year so named, but where military campaigns are mentioned the event probably belongs to the previous year. These date lists establish a synchronism between Hammurabi and Rim-Sin which leads to a date about 2175 for the commencement of the rival dynasties of Isin and Larsa, subject to an error not greater than the date given for the 1st dynasty. Similarly, the 3rd dynasty of Ur of which date-lists are extant may be dated 2282-2175 with the same error. Probably less than seven years actually passed between the accession of Utu-khegal, who ended the oppression by the foreign dynasty of Gutium, and Ur-Nammu's assumption of sovereignty in 2282; this places the Gutium dynasty about 2375-2287, with an increased margin of error. Dating earlier than this is a matter of speculation, for the king-lists, which are complete, give figures that cannot be checked, and for earlier dynasties quite impossible reigns are assigned. There is a general probability that Sargon of Agade commenced his reign between 2550 and 2525, and that the 4th dynasty of Kish began to rule not earlier than 2580. An estimate for the 1st dynasty of Ur, the third after the Flood, based upon comparison with objects from Lagash and the generations, would assign a date between 3000 and 2900 for the commencement of that dynasty, the earliest historical kings known belonging to it. (S. SM.)

HINDU

The early Hindu astronomers selected a period in the course of which a given order of things is completed by the sun, moon and planets returning to the state of conjunction from which they started. This is known as the Great age of 4,320,000 sidereal solar years, the aggregate of the *Krita* or Golden age, the *Trëta* or Silver age, the *Dvâpara* or Brazen age, and the *Kali* or Iron age (in which we now are). There is, however, the system of the *Kalpa* or aeon, consisting of 1,000 (or 1,008) Great ages.

The Hindus now recognize three standard sidereal solar years determined in that manner. (1) A year of 365 days 6 hours 12 min. 30 sec. according to the *Āryabhaṭīya*, otherwise called the *First Ārya-Siddhānta*, which was written by the astronomer Āryabhaṭa (b. A.D. 476); this year is used in the Tamil and Malayālam districts, and in Ceylon. (2) A year of 365 days 6 hours 12 min. 30.915 sec. according to the *Rājamṛigā ka*, a treatise based on the *Brāhma-Siddhānta* of Brahmagupta (b. A.D. 598) and attributed to king Bhōja, of which the epoch, the point of time used in it for calculations, falls in A.D. 1042: this year is used in parts of Gujarāt (Bombay) and in Rājputānā and other western parts of Northern India. (3) A year of 365 days 6 hours 12 min. 36.56 sec. according to the present *Sūrya-Siddhānta*, a work of unknown authorship which dates from probably about A.D. 1000: this year is used in almost all the other parts of India. According to modern science, the true mean sidereal solar year measures 365 days 6 hours 9 min. 9.6 sec., and the mean tropical year measures 365 days 5 hours 48 min. 46.054440 seconds.

The result of the use of this sidereal solar year is that the beginning of the Hindu astronomical solar year, and with it the civil solar year and the lunar year and the nominal incidence of the seasons, has always been, and still is, travelling slowly forward in our calendar year by an amount which varies according to the particular authority. For instance, Āryabhaṭa's year exceeds the Julian year by 12 min. 30 seconds. This amounts to exactly one day in 115½ years, and five days in 576 years. Thus, if we take the longer period and confine ourselves to a time when the Julian calendar (old style) was in use, according to Āryabhaṭa the Mēsha-saṁkrānti began to occur in A.D. 603 on March 20 and in A.D. 1179 on March 25. The intermediate advances arrange themselves into four steps of one day each in 116 years, followed by one step of one day in 112 years: thus, the Mēsha-saṁkrānti began to occur on March 21 in A.D. 719, on March 22 in A.D. 835, on March 23 in A.D. 951, and on March 24 in A.D. 1067 (whence 112 years take us to March 25 in A.D. 1179). It is now occurring sometimes on April 11, sometimes on the 12th; having first come to the 12th in A.D. 1871. (See CALENDAR: Hindu.)

Eras.—The Kalachuri or Chēdi era, commencing in A.D. 248 or 249, is known best from inscriptional records, which range from the 10th to the 13th century A.D., of the Kalachuri kings of the Chēdi country in Central India; and from them it derived its name. In earlier times, this era was well established, without any appellation, in Western India, in Gujarāt and the Thāṇa district of Bombay, where it was used by kings and princes of the Chalukya, Gurjara, Sēndraka, Kaṭachchuri and Traikūṭaka families. It is traced back there to A.D. 457, to the reign of a Traikūṭaka king named Dahrasēna. Beyond that point, we have at present no certain knowledge about it. But it seems probable that its founder was an Abhira king Īśvarasēna, or his father Śivadatta, who was reigning at Nāsik about A.D. 248–249.

The Gupta era, commencing in A.D. 320, was founded by Chandragupta I., the first paramount king in the great Gupta dynasty of Northern India. When the Guptas passed away, their reckoning was taken over by the Maitraka kings of Valabhī, who succeeded them in Kāthiāwār and some of the neighbouring territories; and so it became also known as the Valabhī era.

From Halsī in the Belgaum district, Bombay, we have a record of the Kadamba king Kākusthavarman, which was framed during the time when he was the Yuvarāja or anointed successor to the sovereignty, and may be referred to about A.D. 500. It is dated in "the eightieth victorious year," and thus indicates the preservation of a reckoning running from the foundation of the Kadamba dynasty by Mayūravarmān, the great-grandfather of Kākusthavarman. But no other evidence of the existence of this era has been obtained.

The records of the Gāṅga kings of Kaliṅganagara, which is the modern Mukhalingam-Nagarikatakam in the Gaijām district, Madras, show the existence of a Gāṅga era, which ran for at any rate 254 years. And various details in the inscriptions enable us to trace the origin of the Gāṅga kings to Western India, and to place the initial point of their reckoning in A.D. 590, when a cer-

tain Satyāśraya-Dhruvarāja-Indravarmān, an ancestor and probably the grandfather of the first Gāṅga king Rājasimha-Indravarmān I., commenced to govern a large province in the Konkan under the Chalukya king Kirtivarman I.

An era beginning in A.D. 605 or 606 was founded in Northern India by the great king Harshavardhana, who reigned first at Thāṇēsār and then at Kanauj, and who was the third sovereign in a dynasty which traced its origin to a prince named Naravardhana. This era continued in use for apparently four centuries after Harshavardhana, though his line ended with him.

The inscriptions assert that the Western Chālukya king Vikrama or Vikramāditya VI. of Kalyāṇi in the Nizam's dominions, who reigned from A.D. 1076 to 1126, abolished the use of the Śaka era in his dominions in favour of an era named after himself. He or his ministers adopted, for the first time in that dynasty, the system of regnal years, according to which, while the Śaka era also remained in use, most of the records of his time are dated, not in that era, but in the year so-and-so of the Chālukya-Vikrama-kāla or Chālukya-Vikrama-varsha, "the time or years of the Chālukya Vikrama." There is some evidence that this reckoning survived Vikramāditya VI. for a short time. But his successors introduced their own regnal reckonings; and that prevented it from acquiring permanence.

In Tirhut, there is still used a reckoning which is known as the Lakshmaṇasēna era from the name of the king of Bengal by whom it was founded. The exact initial point of this reckoning appears to be in A.D. 1119. This era prevailed at one time throughout Bengal, from a passage in the *Akbar-nāma*, written in A.D. 1584, which specifies the Śaka era as the reckoning of Gujarāt and the Dekkan, the Vikrama era as the reckoning of Mālwa, Delhi and those parts, and the Lakshmaṇasēna era as the reckoning of Bengal.

The Rājyābhishēka-Śaka, "the era of the anointment to the sovereignty," was in use for a time in Western India. It dated from the day Jyāishṭha śukla 13 of the Śaka year of 1597 current, = June 6, A.D. 1674, when Śivaji, the founder of the Marāṭhā kingdom, had himself enthroned.

There are four reckonings which it is difficult at present to class exactly. Two inscriptions of the 15th and 17th centuries, recently brought to notice from Jēsalmēr in Rājputānā, present a reckoning which postulates an initial point in A.D. 624 or in the preceding or the following year, and bears an appellation, Bhāṭika, which seems to be based on the name of the Bhāṭṭi tribe, to which the rulers of Jēsalmēr belong. No historical event is known, referable to that time, which can have given rise to an era. It is possible that the apparent initial date represents an epoch, at the end of the Śaka year 546 or thereabouts, laid down in some astronomical work composed then or soon afterwards and used in the Jēsalmēr territory. But it seems more probable that it is a purely fictitious date, set up by an attempt to evolve an early history of the ruling family.

In the Tinnevely district of Madras, and in the territories of the same presidency in which the Malayālam language prevails, namely, South Kanara below Mangalore, the Malabar district, and the Cochin and Travancore States, there is used a reckoning which is known sometimes as the Kollam or Kōlamba reckoning, sometimes as the era of Paraśurāma. The years of it are solar: in the southern parts of the territory in which it is current, they begin with the month Simha; in the northern parts, they begin with the next month, Kanyā. The initial point of the reckoning is in A.D. 825; and the year 1076 commenced in A.D. 1900. The popular view about this reckoning is that it consists of cycles of 1,000 years; that we are now in the fourth cycle; and that the reckoning originated in 1176 B.C. with the mythical Paraśurāma, who exterminated the Kshatriya or warrior caste, and reclaimed the Konkan countries, Western India below the Ghauts, from the ocean. But the earliest known date in it, of the year 149, falls in A.D. 973; and the reckoning has run on in continuation of the thousand, instead of beginning afresh in A.D. 1825. It seems probable, therefore, that the reckoning had no existence before A.D. 825. The years are cited sometimes as "the Kollam year (of such-and-such a number)," sometimes as "the year (so-and-

so) after Kollam appeared"; and this suggests that the reckoning may possibly owe its origin to some event occurring in A.D. 825, connected with one or other of the towns and ports named Kollam, on the Malabar coast; perhaps Northern Kollam in the Malabar district, perhaps Southern Kollam, better known as Quilon, in Travancore. But the introduction of Paraśurāma into the matter, which would carry back (let us say) the foundation of Kollam to legendary times, may indicate, rather, a purely imaginative origin. Or, again, since each century of the Kollam reckoning begins in the same year A.D. with a century of the Saptarshi reckoning, this reckoning may be a southern offshoot of the Saptarshi reckoning, or at least may have had the same astrological origin.

In Nēpāl there is a reckoning, known as the Nēwār era and commencing in A.D. 879, which superseded the Gupta and Harsha eras there. One tradition attributes the foundation of it to a king Rāghavadēva; another says that, in the time and with the permission of a king Jayadēvamalla, a merchant named Sākhwāl paid off, by means of wealth acquired from sand which turned into gold, all the debts then existing in the country, and introduced the new era in commemoration of the occurrence. The era may have been founded by some ruler of Nēpāl: but nothing authentic is known about the particular names mentioned in connection with it. This era appears to have been discarded for State and official purposes, in favour of the Śaka era, in A.D. 1768, when the Gūrkhās became masters of Nēpāl; but manuscripts show that in literary circles it has remained in use up to at any rate A.D. 1875.

Inscriptions disclose the use in Kāthiāwār and Gujarāt, in the 12th and 13th centuries, of a reckoning, commencing in A.D. 1114, which is known as the *Simha-samvat*. No historical occurrence is known, on which it can have been based, and the origin of it is obscure.

The eras mentioned above have for the most part served their purposes and died out. But there are three great reckonings, dating from a very respectable antiquity, which have held their own and survived to the present day. These are the Kaliyuga, Vikrama and Śaka eras. The Kaliyuga era is the principal astronomical reckoning of the Hindus. It is frequently, if not generally, shown in the almanacs: but it is not now in practical use for civil purposes; and in previous times we have instances of its use in inscriptions from Southern India, one of A.D. 634, one of A.D. 770, three of the 10th century, and then, from the 12th century onwards, but more particularly from the 14th, a certain number of instances extremely small in comparison with the use of the Vikrama and Śaka eras and other reckonings: from Northern India the earliest known instance is A.D. 1169 or 1170, and the later ones number only four. Its years are by nature sidereal solar years, commencing with the Mēsha-samkrānti, the entrance of the sun into the Hindu constellation and sign Mēsha, i.e., Aries (for this and other technical details, see above, under the Calendar); but they were probably cited as lunar years in the inscriptional records which present the reckoning; and the almanacs appear to treat them either as Mēshādi civil solar years with solar months, or as Chaitrādi lunar years with lunar months *amānta* (ending with the new-moon) or *pūrṇimānta* (ending with the full-moon) as the case may be, according to the locality. Its initial point lay in 3102 B.C.; and the year 5002 began in A.D. 1900.

The Vikrama Era, the earliest of all the Hindu eras, is the dominant era and the great historical reckoning of Northern India—that territory on the north of the rivers Nerbādā and Mahānadi to which part of the country its use has always been practically confined. Like, indeed, the Kaliyuga and Śaka eras, it is freely cited in almanacs in any part of India; and it is sometimes used in the south by immigrants from the north: but it is, by nature, so essentially foreign to the south that the earliest known inscriptional instance of the use of it in Southern India only dates from A.D. 1218, and the very few later instances, prior to the 15th century A.D., come, along with that of A.D. 1218, from the close neighbourhood of the dividing-line between the north and the south. The Vikrama era has never been used for

astronomical purposes. Its years are lunar, with lunar months, though sometimes regarded as solar, with solar months, when cited in almanacs of Southern India which present the solar calendar. Originally they were Kārttikādi, with *pūrṇimānta* months (ending with the full-moon). They now exist in the following three varieties: in Kāthiāwār and Gujarāt, they are chiefly Kārttikādi, with *amānta* months (ending with the new-moon); and they are shown in this form in almanacs for the other parts of the Bombay Presidency: but there is also found in Kāthiāwār and that neighbourhood an Āshādhādi variety, commencing with *Āshāḍha śukla 1*, similarly with *amānta* months; in the rest of Northern India, they are Chaitrādi, with *pūrṇimānta* months. The era has its initial point in 58 B.C., and its first civil day, *Kārttika śukla 1*, is Sept. 19, in that year if we determine it with reference to the Hindu Tūla-samkrānti, or October 18, if we determine it with reference to the tropical equinox. The years of the three varieties, Chaitrādi, Āshādhādi and Kārttikādi, all commence in the same year A.D.; and the year 1958 began in A.D. 1900.

The Śaka Era, which had its origin in the south-west corner of Northern India, is the dominant era and the great historical reckoning of Southern India. It is also the subsidiary astronomical reckoning, largely used, from the 6th century A.D. onwards, in the *Karaṇas*, the works dealing with practical details of the calendar, for laying down epochs or points of time furnishing convenient bases for computation. As a result of that, it came to be used in past times for general purposes also, to a limited extent, in parts of Northern India. And it is now used more or less freely, and is cited in almanacs everywhere. Its years are usually lunar, Chaitrādi, and its months are *pūrṇimānta* (ending with the full-moon) in Northern India, and *amānta* (ending with the new-moon) in Southern India; but in times gone by it was sometimes treated for purposes of calculation as having astronomical solar years, and it is now treated as having Mēshādi civil solar years and solar months in those parts of India where that form of the solar calendar prevails. It has its initial point in A.D. 78; and its first civil day, *Chaitra śukla 1*, is March 3 in that year, as determined with reference either to the Hindu *Masamīkrānti* or to the entrance of the sun into the tropical Pisces. The year 1823 began in A.D. 1900. (X.)

GREEK

The difficulty besetting Greek chronology, for ancient and modern investigators alike, is the absence, for the earlier periods especially, of a universally understood era, corresponding to our reckoning, B.C. or A.D., or the Muslim, dating from the Hejira. Generally speaking, each state had its own fashion of dating, the usual method of specifying time being to name the annual magistrate who was then in office, as "in the archonship of Apsephion," or a king, priest etc., as "in the reign of King Agis," "in the third year of such a one's tenure of office as priestess of Hera at Argos." This had the grave disadvantage that unless a list of the functionaries in question was available, the date was unintelligible. Hence the best-known of them, the Athenian archons, were most commonly referred to, and often several parallel dates were given, as "when Chrysis had been priestess at Argos for 47 years, Aenesuis being then ephor at Sparta, Pythodorus having yet four months left of his archonship at Athens" (Thucydides, ii., 2, 1; = April, 431 B.C.).

Dating by Olympiads.—Gradually, however, the system of dating by Olympiads came into use; this was much more convenient, for the successive celebrations of the festival at Olympia were numbered, not merely named, and the date of the first was conventionally fixed at 776 B.C. of our reckoning. This is due largely to the Alexandrian chronologists, Eratosthenes and the rest, who also drew up the received list of Olympiads. There remained, however, a further difficulty, viz., that various Greek civic years started at different times (see *CALENDAR: Greek*); hence there was often used a conventional Olympiad, beginning at the Attic new year, the summer solstice.

The diligence of the Alexandrians resulted in a fairly satisfactory chronology being drawn up for the fully historical periods,

i.e., back to about 600 B.C.; from about 500 onwards the number of dates which are seriously doubtful, where the ancient evidence survives, is comparatively small, although minor divergencies are common. But for earlier times, and especially before the beginning of the series of Olympiads (itself not very dependable until Olymp. 50), even the ancient investigators had but few documents to go upon, and were obliged to trust largely to genealogies. By comparing these, they made out a pre-historic and proto-historic chronology, arrived at by allowing three generations to a century. Supposing the genealogies to be authentic and complete, this was a tolerably accurate method; but, although they contained a large element of real tradition, we know enough of them to be sure that they were often interpolated, telescoped by the omission of obscure persons, and otherwise corrupted; so that the earlier dates, such as that of the fall of Troy, must be taken as being, at best, very rough approximations.

The ancient chronologists are represented, for us, by a few historians, such as Diodorus of Sicily, who adopt the annalistic method, and by the Christian chronologists, such as Eusebius and his Latin translator and continuator, S. Jerome, also by later writers, such as Iulius Africanus and Georgius Syncellus. The desire of apologists to prove the Biblical revelation earlier than any other led to the prominence of this branch of learning among them, and to the creation of a new, Hebraizing chronology, made by combining the existing systems with data from the Old Testament. Although uncritical and biased, these writers are of immense value to modern historians of antiquity.

Contribution of Archaeology.—Further help is given by the results of modern archaeology. By careful and minute study of the details of artistic technique, the stratification of material remains of all sorts, the styles of pottery, coins, and other common objects, and comparison with the comparatively few pieces which are in some way dated (*e.g.*, by bearing the name of an owner or dedicator whose epoch is accurately known) it is possible, not only to determine often within a few years and not infrequently with much greater exactness the date of objects found, but also by working backwards to come to reasonable conclusions as to the epoch of many events long previous to documentary history, whereof only vague accounts, largely mythological, had come down to us. Thus, the stratification of the seven cities at Hissarlik, the ancient Troy, has given us a relative chronology, or order of events, for the history of that place; while careful comparison of the finds there with those from Cretan and Mycenaean sites, and of these again with certain Egyptian and other documents which can be at least approximately dated, is gradually enabling us to fix, at any rate within a century or so, the absolute date of Agamemnon's expedition. But at present such dates must be largely provisional, and subject to revision, sometimes of a sweeping kind, in the light of further discoveries. For instance, there are differences of some four centuries in the dating of the Dorian invasion, and even doubts as to its historicity.

It is usual, in giving an ancient date, to extend the Julian period backwards and speak, for instance, of March 2, 290 B.C., meaning the day which would have been so styled if the Greeks of that time had had our calendar and could have foreseen when our era would begin. As these imaginary Julian years frequently cut across the real Greek ones, it is best, when the year only is given, to use a double date and say, for instance, 501/500 B.C.

In dealing with events in late Greek history (Roman and Byzantine epochs) we frequently find non-Greek systems used, such as the Julian calendar. For these, see under *Roman Chronology*.

The most important ancient works are cited in the text. For modern authorities, see *CALENDAR: Greek* and *GREECE: History*. Of modern writers on chronology, Clinton (*Fasti Hellenici*, 3 vols., 1834) is still useful, although needing much correction in detail.

ROMAN

Roman chronology was in antiquity wholly dependent upon Greek methods, and hence suffered from all the drawbacks of the latter (see *CHRONOLOGY: Greek*), together with a further one, viz., the scarcity and untrustworthiness of native documents. Working along the lines of the Alexandrians, several Roman scholars, notably Varro and Atticus (the friend of Cicero) arrived at chrono-

logical schemes for the early history of Rome, whereof considerable fragments have come down to us in the various historians and antiquarians whose works survive, in lists of magistrates such as the fragmentary *Fasti Capitolini*, and in S. Jerome's chronicle. They are without exception highly untrustworthy for the regal period and the earlier centuries of the Republic (see *ROME, History*), but at least provide us with an epoch by which to reckon: that from the conventional date (753 B.C. of our reckoning) of the foundation of Rome.

Founding of Rome.—Even this date was by no means a matter on which unanimity was reached; that given is the one which ultimately found most favour, and to which the majority of ancient authors refer when they use the expression *a.u.c.* (*ab urbe condita*, or *anno urbis conditae*). The official method of dating was by consuls, as *M. Messalla et M. Pupio Pisone consulibus* (abbreviated *cos.* or *coss.*), "in the consulship of Marcus Messalla and Marcus Pupius Piso" (Caesar, *de bell. Gall.*, 1, 2, 1 (61 B.C.). This never quite went out of use; but under the empire, official documents emanating from the emperors or referring to them reckoned by their years of tribunician power, to which were frequently added other, less regularly recurring, distinctions, such as the consulate or the salutation as *imperator*, *e.g.*, *Imperator Caesar Vespasianus Augustus pontifex maximus, tribuniciae potestatis viii, imp(erator) xix, consul viii, i.e.*, "Vespasian (name and titles in full), in the ninth year of his tribunician power, having been saluted *imperator* 18 times, consul for the eighth time" (A.D. 77; from an official letter *C.I.L.*, II, 1423). As, however, documents relating to the emperors are very numerous, this method of dating seldom raises much difficulty; our list of consuls also, for the fully historical periods, is tolerably complete. Naturally, in dealing with pre-Caesarian years (see *CALENDAR, Roman*) calculations more or less elaborate are needed to convert the year *urbis conditae* into the conventional Julian year (cf. *CHRONOLOGY: Greek*). These are based on a few facts, such as the mention of an eclipse or other event which we can date accurately. One such eclipse was that of the sun on Oct. 19, 202 B.C.; we gather from various authors that its civic date was about the beginning of December, and this enables us to calculate the condition of the calendar at that time.

Julian Calendar.—The reformed calendar of Julius Caesar was not imposed by Rome on her empire, but naturally it was widely adopted in various modifications. It became the calendar of Christian Rome and also of Constantinople; but gradually a change was made in the era; the supposed date of the birth of Christ replacing that of the foundation of the city (Christian or Dionysian era). This, however, was very slow to win official recognition, despite its convenience; Charlemagne appears to have been the first secular authority to use it. Before that, Christian chronologists used frequently to reckon in years of Abraham, *i.e.*, from his birth, which was placed by Eusebius at a date corresponding to Oct. 2016 B.C.

More important for the determining of Roman imperial dates, than the former, and for some of the later Republican dates also, are the provincial eras and the indictions. It was a wide-spread custom in Hellenistic times to count years from some notable event. The accession of the reigning king was, and continued to be, commonly used, and this, as we have seen, was followed by the emperors; but the Seleucidae and their subjects counted from 312/11 B.C., the date of Seleucus Nicator's decisive victory at the battle of Gaza and his capture of Babylon. In like manner a few Roman chronologists counted from 46 B.C., the date of the Julian reform; and Spain had an era of its own, beginning with 38 B.C., a date chosen for no very obvious reason. Again, several independent cities, such as Antioch, had local eras. When, therefore, we find a year mentioned in an inscription or other piece of evidence, it is necessary to know where this was written, and thus whether the Seleucid era, or that of Spain, or Antioch, or some other place, is meant; or, if the author be a historian, whether he may be using some peculiar era of his own, counting, for example, from the date which he accepts for the fall of Troy, or from the death of Alexander the Great.

The indictions are late, but important for late events, for they

appear in all manner of official documents, ecclesiastical and secular. Properly, *indictio* means an assessment of taxes; *nec novis indictionibus pressi ad vetera tributa deficiunt*, says the younger Pliny (*Paneg.* 29), "the provincials are not so ground down with fresh exactions as to be unable even to pay the old taxes." Under Diocletian, a five-yearly assessment was ordered, and three of these periods grouped together made what was now called an indiction. One authority traces this arrangement back to comparatively early times, making the first indiction begin in 49 B.C.; but the real date seems to be A.D. 297, although even at the beginning of the empire the germ of such a system existed in Egypt. Its chronological importance is, that it provided a means of dating, without mentioning the several emperors who, by Diocletian's arrangement, ruled simultaneously. A disadvantage was that the cycle began on different days at different times and places. Despite these differences, and the fact that *indictio* meant now the whole cycle, now a year of it, it remained in use until the middle ages, and here and there even later.

See CHRONOLOGY: *Greek*; CALENDAR: *Greek*; CALENDAR: *Roman*; also Clinton, *Fasti Romani*, vol. i., 1845, vol. ii., 1850; Seeck, art. "Indictio," in Pauly-Wissowa, *Realencyclopädie*, and literature there cited. (H. J. R.)

JEWISH

The era which is in present vogue among Jews (*Anno Mundi*, *li-yitzirah* or *libriath olam*, from the creation of the world) appears not to have come into popular use before the 9th century, though possibly it may have been known to learned writers earlier. The era is supposed to begin, according to the mnemonic *Beharad*, at the beginning of the lunar cycle (see CALENDAR: *Jewish*) on the night between Sunday and Monday, Oct. 7, 3761 B.C., at 11 hours 11½ minutes P.M. This is indicated by *be* (*beth*, two, i.e., 2nd day of week), *ha* (*he*, five, i.e., fifth hour after sunset) and *Rad* (*Resh*, *dalet*, 204 minims after the hour). Rühl's theory that this era existed already in A.D. 222 is disputed by Poznanski on strong grounds. In the Bible various eras occur, e.g., the Flood, the Exodus, the Earthquake in the days of King Uzziah, the regnal years of monarchs and the Babylonian exile. During the exile and after, Jews reckoned by the years of the Persian kings. Such reckonings occur not only in the Bible (e.g., Daniel viii., 1) but also in the Assouan papyri. After Alexander, the Jews employed the Seleucid era (called *Minyan Shetaroth*, or era of deeds, since legal deeds were dated by this era). So great was the influence exerted by Alexander, that this era persisted in the East till the 16th century, and is still not extinct in south Arabia. This is the only era of antiquity that has survived. Others, which fell into disuse, were the Maccabaeon eras, dating from the accession of each prince, and the national era (143-142 B.C.), when Judaea became free under Simon. That the era described in Jubilees (see CALENDAR: *Jewish*) was other than hypothetical, is probable. Dates have also been reckoned from the fall of the second Temple (*Le-Ḥorban hab-bayyith*). The equation of the eras is as follows: 1 after destruction = A.M. 3831 = 383 Seleucid = A.D. 71.

Jewish chronology falls into two periods, biblical and post biblical. With the latter alone is the present article concerned; for the former see BIBLE: *Chronology*. The earliest Jewish chronologies have not survived. Demetrius, a Jew of Alexandria, wrote a treatise in which he endeavoured to deduce the dates of Hebrew history from the Scriptures. Of this work only a very few remnants are extant; they have been published by C. Müller (*Fragmenta Hist. Graecorum*, iii. 214-217). The *Book of Jubilees*, written in the second pre-Christian century, subordinates chronology to its peculiar views on the calendar and theology. For present purposes Josephus must be left out of account, for chronology and history are separate studies. The most important and the earliest of all surviving chronologies is the *Seder 'Olām Rabbah*. This Hebrew book is mentioned in the Talmud; the author and date are unknown, but the authorities cited in the book belong almost exclusively to the 2nd century A.D. According to R. Johanan, the work was transmitted by R. Jose ben Halafta, a pupil of Aqiba, and it is possible that this tradition is correct. The author, whoever he may have been, was possibly the first to

make use of the era of Creation. Owing to defective sources he makes many errors in the Persian period. The chronology extends from the creation of Adam to Bar Kochba's fight for liberty in Hadrian's days, but the period from Alexander to Hadrian is compressed into the end of one chapter. The best edition is that of B. Ratner (Wilna, 1897). Various Latin translations exist (vide bibliography in *Jewish Encyclopedia*, s.v.).

The *Seder 'Olām Zūta*, a smaller work, was written probably in the 8th century; it completes the *Rabbah* and is based on it. The object of the book, which enumerates the 39 generations of Babylonian exilarchs, is to show that the latter were lineal descendants of David. The best text is that of Neubauer, *Mediaeval Jewish Chronicles*, ii., 67.

Megillat Ta'anith, or scroll of Fasting, is a chronicle rather than a chronology, since the events are grouped according to the months of the year and not in chronological sequence. The book enumerates 35 eventful days in five groups: I., pre-Maccabaeon; II., Maccabaeon; III., pre-Sadduceon; IV., pre-Roman; V., the Diaspora. The author was probably, as stated in the Talmud (*Sabbath* 13 b), Hananya ben Hezekiah of the family of Garon, and the date would be about A.D. 7. A Latin translation exists (vide bibliography, s.v. in *Jewish Encyclopedia*, to which add the edition of Solomon Zeitlin, New York, 1922).

Tanna debe Eliyahu, a composite Midrash finally redacted in the 10th century, can scarcely be termed a chronology, since the underlying theme is the growth of the world-system; human history is arranged in *Shittōth* (series) in order to bring the moral into prominence. The absence of dates excludes this book from the category of chronology proper, although it contains much historical information.

For modern purposes the best chronology is that at the end of H. Graetz's *History of the Jews* in the American edition. Others are included in the bibliography in the *Jewish Encyclopedia*, s.v. Chronology. See also M. L. Margolis and A. Marx, *History of Jewish People* (1927). (H. M. J. L.)

MAYA AND MEXICAN

For technical terms relating to the calendar, which must be used to explain the chronology, the reader is referred to article CALENDAR: *Maya and Mexican*.

Maya: The Long Count.—The Maya calendar is based upon a year of 365 days, but it seems clear that the Mayas themselves recognized no such period. In their view 365 days was one tun (360-day period) and five days, and they so expressed the distance from a month-day in one year to the same month-day in the following year; e.g., from 9 Imix 19 Zip to 10 Cimi 19 Zip. They never used a year of 365 days in counting the distance in time from one date to another. No glyph for the 365-day year is found, and there is no word with that meaning in the Books of Chilán Balam. It has been stated that haab meant 365-day year, but in fact it means tun (360-day period). All authorities agree, however, as to the method of counting time. The units used are the kin or day, the uinal of 20 days, the tun of 18 uinals, the katún of 20 tuns, and the cycle of 20 katuns. The Maya name for the cycle is unknown, and until proof is available it is undesirable to give it a hypothetical Maya name. In transcribing Maya numerals the numbers are written with a dash between each. Thus 9-10-6-5-9 means 9 cycles, 10 katuns, 6 tuns, 5 uinals, and 9 kins. By this method the Maya counted the time elapsed from a certain day, 4 Ahau 8 Cumhu, which was the starting-point of their era, and thereby fixed dates in the Long Count, as the Maya era is called. What is called an Initial Series shows the position of a date in the Long Count. Thus 8 Muluc 2 Zip will recur every 52 years, but if it is expressed as an Initial Series date, 9-10-6-5-9, 8 Muluc 2 Zip, its position in time is fixed, as its distance from the starting-point of the Long Count is given. In the Inscriptions an Initial Series always begins the inscription (hence the name) and commences with an "introducing glyph" which appears merely to mean "This is an Initial Series." Then follow the Maya numerals written in descending order, that is commencing with the largest period (cycle) and ending with the kin, and then the terminal date (in the above example, 8 Muluc

2 Zip). More often than not, the day number and day name (as 8 Muluc) are separated from the month day (as 2 Zip) by a Supplementary Series. In such cases the month day regularly follows the last glyph of the Supplementary Series. A date which is not fixed in the Long Count is called a "Calendar Round date," as it can recur every 52 years.

Another method of giving dates is by "period-endings." This somewhat resembles the European method of giving the last two figures of the year without the century. Thus '98 may mean 1798 or 1898, etc., recurring every 100 years. But the Maya method differs in that it always denotes a certain day instead of a larger period such as a year, and further it is a day terminating a certain round number. It is as if the European method only denoted Dec. 31, and then only when it ended a decade or century. The most usual period-ending is the katun-ending. This is expressed by (1) a glyph meaning "ending," (2) the number of the katun, (3) the Calendar Round date on which a katun of such a number ended. Example: "Ending Katun 13, 8 Ahau 8 Uo." Such a date cannot occur again in the Long Count for 374,400 years, so it is fixed as effectually as if the Initial Series had been given. The "ending sign" may be omitted. Less common are cycle-ending dates, as "2 Ahau 3 Uayeb ending Cycle 2." These cannot recur for 748,800 years. Very common are the lahuntun-endings, expressed by a special glyph meaning "end of Tun 10" together with the Calendar Round date. This means Tun 10 from the last katun-ending. These cannot recur for 18,720 years. Also common are the hotun-endings, expressed by a special glyph meaning "end of Tun 5" and the Calendar Round date. This Tun 5 may mean either Tun 5 from the last katun or Tun 5 from the last lahuntun (therefore Tun 15 from the last katun). These cannot recur for 9,360 years and are, therefore, practically as much fixed as the others. Example: "4 Ahau 13 Mol, Hotun." This must be 9-11-15-0-0 4 Ahau 13 Mol, because that date does not end Tun 5 or 15 elsewhere in cycles 8, 9 or 10 or indeed for 9,360 years before or after. No other satisfactory case of tun-ending occurs in the old empire except the 13- tun ending, expressed by glyphs meaning "ending Tun 13" and the Calendar Round date. These cannot recur for 18,720 years. As all period-endings denote the ends of even periods in the Long Count which itself starts from 4 Ahau 8 Cumhu, they must themselves all end on a day Ahau.

Many dates in the inscriptions are connected with other dates by "Secondary Series" numbers. If a date is connected by a Secondary Series with another date which is fixed in the Long Count, then the former date is called a Secondary Series date and is, of course, itself fixed in the Long Count, as it can be calculated by the Secondary Series from the known date. Example: "6 Imix 19 Zotz, connected by Secondary Series of 2-1-13-19 with 4 Ahau 13 Mol." But the latter is fixed by a period-ending in same inscription as 9-11-15-0-0 4 Ahau 13 Mol. so the former is 9-9-13-4-1 6 Imix 19 Zotz. But dates may be connected by a Secondary Series, and neither of them may be fixed in the Long Count, in which case both are merely Calendar Round dates.

All Initial Series in the Dresden Codex, and all except two in the inscriptions, start from 4 Ahau 8 Cumhu. But there are two Initial Series in the inscriptions which start from a date 4 Ahau 8 Zotz which occurred 13 cycles before the date 4 Ahau 8 Cumhu, the starting-point of all the rest. In the Dresden Codex a "great cycle" is used containing 20 cycles. Dr. Sylvanus G. Morley shows that this was used in the inscriptions, and also a great-great cycle of 400 cycles, and a great-great-great cycle of 8,000 cycles. This has been confirmed by Long's discovery of a new interpretation of an inscription at Palenque.

It will be noted that all the Maya time periods (except the tun) are each 20 times the next lower one. In the inscriptions these numbers are written with the glyphs for the periods as well as the numbers. Thus 9-10-0-0-0, if an Initial Series, is expressed by glyphs reading 9 cycles, 10 katuns, 0 tuns, 0 uinals, 0 kins. This is similar to the usual mode of writing measures; e.g., roft. 11in. Secondary Series are written in the same manner except that in them the lowest denomination (kin) comes first and the highest last. There are only three or four Secondary Series which

do not follow this order, all at Palenque. But in the Dresden Codex the glyphs for the periods are omitted, and the value of the numbers depends upon position alone, as in the Arabic numerals.

Cyrus Thomas remarks that there is nothing to show that the 4 Ahau 8 Cumhu to which the Initial Series count back is the same in actual time in all. This is so, because 4 Ahau 8 Cumhu will recur every 52 years. But Thomas agrees that the assumption that it is the same actual day in all gives the most credible result, as this makes the terminal dates of the inscriptions fall within a reasonable distance of each other, and no doubt the assumption is correct. The earliest dated monument is Stela 9 at Uaxactun, 8-14-10-13-15 and the latest in the old empire is Stela 12 at the same site and is 10-3-0-0-0. This gives an extreme range of 1-8-9-4-5 (about 561 years), quite a probable time for any phase of civilization to last. But since the Maya erected the first dated monument about 3,443 years after the beginning of their era, it is clear that 4 Ahau 8 Cumhu represents no historical event and must have fallen long before there was any Maya civilization. Like the Julian period used by astronomers, it was a date calculated by skilled chronologists long after the invention of the calendar, doubtless with the object of harmonizing lesser periods.

But in general the range of Maya dates is even shorter. Many of the monuments record only one date, and where there are several the last date, or at least the last period-ending, seems generally to be the contemporaneous one. Now the dated monuments are very rare in cycle 8, more numerous, but still confined to a few sites, from 9-0-0-0-0 to 9-10-0-0-0, become very numerous from 9-10-0-0-0 to 9-15-0-0-0, increase much more after 9-15-0-0-0, reach a maximum in 9-18-0-0-0, and then suddenly diminish, becoming much fewer after 9-19-0-0-0, and ceasing after 10-3-0-0-0. The style of the monuments likewise shews a steady advance in art up to about 9-18-0-0-0. Change is also observable in the method of dating. In cycle 8 the monuments were erected on casual dates which did not end any tun or other time period, and the dates were usually shewn by Initial Series, but early in cycle 9 the practice was adopted of setting up the monuments to mark each hotun. Unfortunately hotun is used by Maya scholars in this case to mean the end of either a katun, lahuntun, or hotun, that is, it means any number of tuns of the Long Count which is divisible by five. Initial Series were still used, and at about 9-8-15-0-0 the practice began of giving several dates on a monument besides the Initial Series, the last one marking the hotun. After 9-10-0-0-0 monuments dated by period-endings became fairly frequent, and after 9-15-0-0-0 the Initial Series became rarer, and monuments were dated mostly by period-endings or Calendar Round dates. Geographically we also see change. The old empire area was roughly triangular with Uaxactun and Tikal in the north-east, Copan and Quirigua in the south-east, and Piedras Negras in the west. Uaxactun and its neighbour, Uoluntun, alone show dates in cycle 8. In the first half of cycle 9 the monuments are almost confined to Uaxactun, Tikal, Copan and Piedras Negras, outliers in the area, while after 9-10-0-0-0 they are numerous everywhere till 9-18-0-0-0, when they cease at Piedras Negras and the west, ceasing at Quirigua and Copan and the south-west after 9-19-0-0-0. Some new cities appear towards the close of cycle 9 in the north-east, and the closing date is at Uaxactun and Xultun near it. It is noteworthy that Uaxactun and Tikal, though at the north-east of the old empire, are almost in the centre of the whole Maya area if we consider the old and new empire territories together, and these sites were probably the original seats of the Maya.

The New Empire.—The Long Count was wanting in the new empire. Instead they used the U Kahlay Katunob, which was a simplification of the older period-ending method. The cycle had entirely dropped out of use, and the only periods were the katun and the tun, the katun being the more important. The katuns were cited by the day Ahau with its day number on which they ended. Thus "Katun 13 Ahau" or simply "13 Ahau." Such a date can recur every 13 katuns (about 256 years) because in

that time the 13 day numbers will be exhausted. The order of succession is 13 11 9. 7. 5 3. 1, 12 10. 8 6. 4. 2. Often nothing was mentioned save the katun in which the event occurred, so that not only could the katun recur about every 256 years, but the event might have occurred anywhere within the katun, leaving about 20 years uncertainty. At times an event is described as occurring in tun so-and-so of such a katun, thus fixing it within a period of 360 days within the katun. But if the Calendar Round date is given as well, as e.g., "Katun 13 Ahau, Tun 13, 9 Imix 18 Zip," then (depending upon what date it is) the date can either only occur once in 18,720 years or can occur twice in that time, at intervals of 7,436 years and 11,284 years respectively.

Correlations.—The state of knowledge about the Maya of the old empire has no parallel in archaeology. While on the one hand we do not even know the names of the peoples who erected the monuments, much less their history, nor even if they spoke Maya, seeing that all knowledge of the calendar is based upon Landa's account of the new empire, yet so accurate were their dates that it is possible to date the monuments with regard to each other to the exact day. But widely different views are held by scholars as to the correlation with Christian chronology. The principal elements of the problem are: (1) correlation of the old and new empire chronologies, (2) correlation of the new empire and Christian chronologies, (3) correlation with astronomical discoveries of Teeple. (1) If the month-days on which the katuns of the new empire ended had been stated, there would have been an absolute correlation with the old empire. A tun ends on the same day number every 13 tuns, but will end on the same month-day only every 73 tuns, and on the same day number and month-day only every 949 tuns. Similarly a katun will only end on the same day number and month-day every 949 katuns (18,720 years). But as the new empire method did not state the month, the Katun 13 Ahau which occurred in the 16th century is identified with various katuns of the Long Count by different writers. The Books of Chilán Balam carry back the new empire chronology to about A.D. 163. Mr. J. Eric Thompson alone shortens this. (2) Opinions differ as to what year in the 16th century a katun 13 Ahau ended in, so the new empire chronology is only loosely correlated with Christian chronology within the limits of about a katun. The Maya year was a shifting one and Landa says that in his time Pop began on July 16 O.S. This was in or near 1553. No correlation can stand which does not agree with Landa's statement, consequently all are ruled out but the three given below. (3) Teeple shows certain lunar and Venus dates agreeing with Thompson, but probably the last word has not yet been said on this subject.

The Bowditch correlation depends on a statement as to the month-day and has considerable historical evidence in its favour. Thompson's correlation depends on another statement as to the month-day and raises some difficulties owing to the shortness of its chronology. Dr. Herbert J. Spinden's correlation is at variance with both of these month-dates and also with Teeple's results. Moreover, the astronomical observations on which he relies have been shown by further measurement to be incorrect. The dates of 4 Ahau 8 Cumhu in these correlations are in the Gregorian Calendar (astronomical reckoning):—

| | |
|--------------------------|-------------------|
| Bowditch, Joyce and Long | Feb. 10 3641 B.C. |
| Spinden | Oct. 14 3373 B.C. |
| Thompson | Aug. 13 3113 B.C. |

As the Maya chronology was the only efficient one in pre-Columbian America it would, if fixed, throw much light on that of America as a whole. Excavation of Maya sites has yielded objects obtained in trade from both northwards and southwards, so that if the correlation was established, the period when these neighbouring cultures flourished could be approximated.

Solving Dates.—A word in conclusion on solving dates. Given such a series as 9-10-6-5-9 and that its starting-point is a known date such as say 4 Ahau 8 Cumhu, the day name can at once be determined by counting the kin number (in this case 9) from the starting-point; thus 9 days from Ahau will reach Muluc. But the finding of the day number and the month-day is a more difficult matter. It is possible to reduce the whole series

to single days and then find the day number by dividing by 13 and counting the remainder forward from the day number of the starting point, similarly to find the month-day by dividing the total number of days by 365 and counting forward the remainder from the month-day of the starting-point. But the student is advised not to use this time-wasting method. Many problems can be solved by tables, of which the best are J. T. Goodman's and those of Mr. Thomas A. Joyce, but not all cases can be directly done by tables, and though they are valuable for checking results, it is well to be able to calculate independently of them. By far the best rule is that of Mr. Raymond K. Morley (*see Bibliography*), by which all series can be quickly calculated without any tables.

Cakchiquel Calendar.—This is the only era found in ancient America except the Maya. It was a pure vigesimal count, the units being the *kih* or day; the *vinak* (meaning "twenty") or 20 *kih*, the *a* or 20 *vinak*, and the *may* or 20 *a*. No higher units are known or were required, as the era only started from the day 11 Ah, the date of the revolt of the Tukuiche tribe, equivalent to May 20 1493 O.S. This era is altogether unique, not only from its purely vigesimal character, but also that it only commenced in the lifetime of persons who were living at the Spanish conquest. No hint of any other era appears in the Annals, before the revolt, but the use of the special words such as *a* and *may* shows that such a mode of counting from some other epoch or epochs had been previously known. The Cakchiquel, living southwards of the old empire, like the Yucatan Maya to the north of it, used a later simplification of the older time counts. Dates were expressed thus: On 1 Ah was completed 1 *may* and 5 *a*; after the revolt, on 12 Camey (a certain event occurred). Sometimes the number of *vinak* and *kih* was also given.

Mexican Calendar.—There was no chronological system beyond the calendar round. The codices show no means of giving the numbers of years elapsed from one date to another except the clumsy one of stating the year-bearers of all the intervening years. The calendar round began with the year 2 Acatl, in which year the great festival of the "year-binding," *xuuhmolpilli*, was held. The codices denote such a year by a special sign along with the year-bearer, but this is merely the same thing as noting the occurrence of such an event in that year. The sign for the year-binding was never used as an arithmetical sign to show that 52 years or a multiple thereof had elapsed. To do this they had to set out all the individual years. Naturally, there is much confusion in Mexican history and the same event is placed by different authorities at varying numbers of calendar rounds before the Spanish conquest. Mexico surrendered to Cortez on the day 1 Coatl, year 3 Calli, which was Aug. 13 1521 O.S. This was 3 Xocouetzi, as the year-bearers were taken from 1 Toxcatl instead of from the first month of the year. The explanation is probably that the monthly festivals were displaced in the shifting calendar to agree with the seasons, but this question is very obscure.

BIBLIOGRAPHY.—C. P. Bowditch, *The Numeration, Calendar Systems, and Astronomical Knowledge of the Mayas* (Cambridge, U.S.A. 1910); T. A. Joyce, *Mexican Archaeology* (London, 1914), and *Guide to the Maudslayi Collections of Maya Sculptures* (British Museum, 1923); S. G. Morley, *An Introduction to the Study of Maya Hieroglyphs* (Washington, Bureau of American Ethnology, 1915), and *The Inscriptions at Copan* (Washington, Carnegie Institution, 1920); R. K. Morley, "Computations for the Maya Calendar" in *American Anthropologist* (1918); R. C. E. Long, "Maya and Christian Chronology," *Journal Royal Anthropological Institute* (1923), "The Age of the Maya Calendar," *Journal Royal Anthropological Institute* (1924), "Maya High Numbers," *Man*. No. 39 (1923), "The Bowditch and Morley Correlations of Maya Chronology," *Man*. No. 2 (1925); J. E. Teeple, "Maya Inscriptions, Glyphs," C. D. & E. of the Supplementary Series, and "Further Notes on the Supplementary Series," in *American Anthropologist* (1925); also "Maya Inscriptions, The Venus Calendar and another Correlation," in *American Anthropologist* (1926); H. J. Spinden, *The Reduction of Mayan Dates* (Cambridge, U.S.A., Peabody Museum); J. E. Thompson, *A Correlation of the Mayan and European Calendars* (Chicago, Field Museum of Natural History, 1927).

The student is recommended to read first Joyce's *Guide*, then his *Mexican Archaeology*, then Morley's *Introduction* (with good bibliography), and then Bowditch. The last two are absolutely essential. Morley's *Copan*, a truly great book, presupposes a knowledge of the subject and contains an extensive bibliography. (R. C. E. L.)

MUSLIM

The Muslim Calendar (*see* CALENDAR: *Muslim*) may evidently be carried on indefinitely by successive addition, provided care be taken to allow for the additional day occurring in bissextile and intercalary years. The purely lunar years of this calendar are partitioned into cycles of 30 years, 19 of which are common years of 354 days each, the remaining 11 being intercalary years having an additional day appended to the last month. The mean length of the year is, therefore, $354\frac{11}{30}$ days (354 days, 8 hours, 48 minutes). This gives $29\frac{12}{25}$ days (29 days, 12 hours, 44 minutes) as a period of mean lunation, and this differs from the astronomical mean lunation by only 2.8 seconds. This small error amounts to a day in about 2,400 years.

To find if a year is intercalary or common, divide it by 30; the quotient will be the number of completed cycles and the remainder will be the year of the current cycle; if this last be one of the numbers 2, 5, 7, 10, 13, 16, 18, 21, 24, 26, 29, the year is intercalary and consists of 355 days; if it be any other number, the year is ordinary.

| Year of the current cycle (y) | | | | Number of the period of seven cycles = $(\frac{C}{7})_r$ | | | | | | |
|-------------------------------|-----|-----|-----|--|-------|-------|-------|-------|-------|-------|
| | | | | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
| 0 | 8 | .. | | Mon. | Sat. | Thur. | Tues. | Sun. | Frid. | Wed. |
| 1 | 9 | 17 | 25 | Frid. | Wed. | Mon. | Sat. | Thur. | Tues. | Sun. |
| *2 | *10 | *18 | *26 | Tues. | Sun. | Frid. | Wed. | Mon. | Sat. | Thur. |
| 3 | 11 | 19 | 27 | Sun. | Frid. | Wed. | Mon. | Sat. | Thur. | Tues. |
| 4 | 12 | 20 | 28 | Thur. | Tues. | Sun. | Frid. | Wed. | Mon. | Sat. |
| *5 | *13 | *21 | *29 | Mon. | Sat. | Thur. | Tues. | Sun. | Frid. | Wed. |
| 6 | 14 | 22 | 30 | Sat. | Thur. | Tues. | Sun. | Frid. | Wed. | Mon. |
| *7 | *15 | *23 | .. | Wed. | Mon. | Sat. | Thur. | Tues. | Sun. | Frid. |
| .. | *16 | *24 | .. | Sun. | Frid. | Wed. | Mon. | Sat. | Thur. | Tues. |

To find from this table the day of the week on which any year of the Hejira begins, the rule to be observed will be as follows:—

Rule.—Divide the year of the Hejira by 30; the quotient is the number of cycles, and the remainder is the year of the current cycle. Next divide the number of cycles by 7, and the second remainder will be the Number of the Period, which being found at the top of the table, and the year of the cycle on the left hand, the required day of the week is immediately shown.

The intercalary years of the cycle are distinguished by an asterisk.

For the computation of the Christian date, the ratio of a mean year of the Hejira to a solar year is:

$$\frac{\text{Year of Hejira}}{\text{Mean solar year}} = \frac{354\frac{11}{30}}{365.2422} = 0.970224.$$

The year 1 began July 16, 622, Old Style, or July 19, 622, according to the New or Gregorian Style. Now the day of the year answering to July 19, is 200, which, in parts of the solar year, is 0.5476, and the number of years elapsed = $Y - 1$. Therefore, as the intercalary days are distributed with considerable regularity in both calendars, the date of commencement of the year Y expressed in Gregorian years is:

$$0.970224 (Y - 1) + 622.5476, \\ \text{or } 0.970224 Y + 621.5774.$$

This formula gives the following rule for calculating the date of the commencement of any year of the Hejira, according to the Gregorian or New Style.

Rule.—Multiply 970.224 by the year of the Hejira, cut off six decimals from the product, and add 621.5774. The sum will be the year of the Christian era, and the day of the year will be found by multiplying the decimal figures by 365.

The result may sometimes differ a day from the truth, as the intercalary days do not occur simultaneously; but as the day of the week can always be accurately obtained from the foregoing table, the result can be readily adjusted.

CHRONOMETER. A marine timekeeper, used for determining longitude at sea. The word was originally used to denote

any time-measuring instrument. The first instance of its employment in its accepted modern meaning is to be found in Jeremy Thacker's "The Longitudes Examined . . ." (London, 1714). On the Continent the analogous term "chronomètre" is still used to describe any high-class timekeeper, whether for marine purposes or otherwise.

History.—The possibility of determining longitude at sea by the use of a timekeeper was first pointed out by the Flemish astronomer Gemma Frisius, in a work on navigation published at Antwerp in 1530. At that date, however, and for long afterwards, the mechanical difficulties in the way of constructing an accurate marine timekeeper appeared to be insurmountable. The first attempt to put Frisius' suggestion into practice was made in 1662–70 by the celebrated Dutch scientist, Christiaan Huyghens, of Zulichem, who constructed several marine timekeepers controlled by pendulums and subjected them to actual tests at sea. It was found that the timekeeping of the machines was quite unreliable, owing to the effects of temperature and of the ship's motion. Many later inventors fared no better, but during 1729–60 John Harrison, a self-taught Yorkshire carpenter, invented and constructed four practical marine timekeepers, with the fourth of which (now preserved, in going order, at Greenwich Observatory) he won the reward of £20,000 offered in 1714 by the British Government for any means of determining a ship's longitude within 30 nautical miles at the end of a six weeks' voyage. It may be noted that a timekeeper fulfilling this condition would have to keep time within three seconds per day—a standard which, at the date when the reward was offered, had not been attained by the best pendulum clocks on shore.

Harrison's mechanism, although unquestionably efficient, was complicated, delicate and costly—the Board of Longitude paid Larcum Kendall, a London watchmaker, £450 for a duplicate of the No. 4 timekeeper. Accordingly, it had little direct effect upon the evolution of the modern chronometer. But in 1765 Pierre Le Roy, of Paris, invented and constructed a marine timekeeper whose mechanism embodied, in an embryonic but perfectly recognizable form, practically all the essential features of the modern chronometer. This machine, or a contemporary duplicate, is preserved in the Conservatoire des Arts et Métiers in Paris. Le Roy's work was followed up by Ferdinand Berthoud in France and by John Arnold and Thomas Earnshaw in England. The last-named produced, as early as 1785, several chronometers which, both in appearance and mechanism, are scarcely distinguishable from the machine of to-day.

Description.—The modern chronometer is, broadly speaking, a large, well-made watch, suspended in gimbals (a set of two bearings at right-angles, connected by a ring) and so poised as to remain horizontal whatever the inclination of the ship. It is thus safeguarded from those alterations of position which slightly affect the timekeeping of even the best watches. In addition, it differs somewhat in its mechanism from an ordinary watch, the spiral balance-spring and lever escapement of the latter being replaced by a helical balance-spring and a spring-detent or "chronometer" escapement. This form of escapement is mechanically superior to any other, and requires no oiling, but it is unsuitable for use in pocket watches, as if stopped it has no tendency to re-start itself. For the purpose of equalizing the force of the mainspring, almost all chronometers are fitted with a device known as a "fusee," which has for some time past been discarded in watches, and their compensation-balances, by which the effects of heat and cold upon their timekeeping are practically nullified, also differ in some respects from the ordinary watch type, as well as being considerably larger and heavier.

Accuracy.—The modern chronometer is capable, with fair usage, of going with what must be regarded, in view of the unfavourable conditions to which it is necessarily exposed on board, as astonishing accuracy. Both during the official tests at Greenwich Observatory (which has been held annually, on practically unaltered lines, from 1844 to 1914) and in their subsequent service afloat, many hundreds of chronometers have shown themselves capable of keeping time in all ordinary variations of temperature for six months together with an error not exceeding a second a day

—an amount which, in a month's voyage along the equator, would involve an error in the ship's final position of less than eight nautical miles. (See also NAVIGATION.)

See R. T. Gould, *The Marine Chronometer, its History and Development* (1923), a general history of the subject. (R. T. Go.)

CHRUDIM, a town of Bohemia, Czechoslovakia, situated in the south-east of the Elbe basin on the Chrudimka, a left-bank tributary of the Elbe. Its fertile surroundings account for the early settlement, dating back to before the 11th century, and for the disturbed history since it became a small but important regional centre with a progressive German population and many royal privileges. Today its function is that of a market centre with a small development of manufactures that express the nature of its district, e.g., sugar, spirits, beer, flour-milling and saw-mills. Pop. (1923), 13,129, predominantly Czech.

CHRYsalis, the common name for the pupa (*q.v.*) of the Lepidoptera (butterflies and moths).

CHRYSANTHEMUM, in botany, a numerous genus of plants of the family Compositae; popularly the name given to forms of certain Old World species of this genus which have been remarkably developed by cultivation. Most varieties of the so-called Chinese and Japanese chrysanthemums extensively grown by gardeners and florists are blended hybrids or other forms derived from *C. morifolium* and *C. indicum*, natives of eastern Asia. Other species of interest to flower growers are *C. coccineum* (pyrethrum), *C. Parthenium* (feverfew), and *C. frutescens* (marguerite). Other representatives of the genus are *C. Balsamita* (costmary) and *C. Leucanthemum* (ox-eye daisy), the latter often a pestiferous weed. The common chrysanthemum has probably been known for at least 2,000 years. In Japan, where it can be traced back many centuries, it is the national flower. Breyer in 1689 was the first European to mention the chrysanthemum, giving it the name of *Matricaria Japonica Maxima*. M. Pierre Louis Blancard introduced the first large-flowering chrysanthemum into England in 1789. This first flowered in 1790. The plant was first introduced into America in 1847. The work of hybridization was first taken up by Dr. H. P. Walcott and later in the '80s by John Thorpe, who organized the Chrysanthemum Society of America in 1890, at which time hybridization seemed to have reached its zenith. At the present day (1929) Elmer D. Smith is probably the leading hybridizer of the chrysanthemum.

Chrysanthemums have been popular with the gardeners, both professional and amateur, as an exhibition flower because of their great size and variety of shape and colour, and also because some varieties are extremely hardy permitting their use in the perennial garden. Chrysanthemums owe their popularity with commercial florists not so much to their value as a crop, but to the fact that they may be planted in the late spring and early summer when the greenhouse otherwise would be empty. Moreover, the chrysanthemum is a quick maturing crop, many varieties being grown without artificial heat, since they bloom from late August to December. The cultural requirements for chrysanthemums may be adjusted to many rotation schemes, so that the same greenhouse may be used for growing other floral crops, as calendulas, sweet-peas, stocks, snapdragons, annuals and lilies.

Classification of Types.—(1) *Incurved Chinese types* are nearly globular in form and regular in outline; the florets are smooth, rounded or somewhat toothed at the top, and sufficiently long to form a graceful curve (commercial varieties are Maj. Bonaffon, Mrs. Nellie T. Ross, Citronelle). (2) *Japanese types* are varieties with long loosely arranged florets; the florets may be flat, fluted, quilled or tubulated, and may be incurved or reflex. Many exhibition varieties (Mrs. H. S. Firestone, F. E. Nash, Miss Ruth C. Twombly, Majestic) come in this type. (3) *Anemones* have high, neatly formed centres with elongated quilled florets, surrounded by flat more or less horizontally arranged ray flowers. Examples are: Gorza, Chestnut, Maple-leaf. (4) *Pompons* may be somewhat flat or nearly globular, generally very neat and compact, formed of short, flat, fluted or quilled florets. The florets of each bloom are all of one form, such as the varieties Varsity, Co-ed, Baby, Pink Dot and Nuggets. (5) *Singles*

are arranged sufficiently close together to form a regular fringe. There may be one or two rows of ray flowers and sometimes as many as three or five. The centres of the florets are always tubular, either short or somewhat elongated. Golden Mensa, Mrs. E. D. Godfrey and Margaret Waite are good examples. (6) *Spidery, plumed and feathery types* are varieties with flowers of eccentric shape; some are light and graceful, while others have threadlike petals. Among the varieties of this class are the Dean, Yellow Jacket, Chief, Sam Caswell, Tachibana and White Thread.

Propagation.—The chrysanthemum is generally propagated by cuttage, seedage or division. Cuttage is by far the most satisfactory. Most of our destructive insects and diseases may be controlled by the careful selection of clean stock to be used for cuttings. Plants grown from cuttings make better growth, give better flowers and are easier to stake and tie in the garden. Nearly all chrysanthemums grown in commercial greenhouses are produced from cuttings. Division is practised by many outdoor gardeners. The only advantage is that the operation is an easy and safe one, but diseases and insects are generally spread with this method. Seedage is practised in chrysanthemum growing only as a means of obtaining new varieties.

Plants for propagation are packed close together in flats, benches or cold frames after the flowering season, and are wintered over in either a cold greenhouse or frame. In March or April these plants send up strong shoots which are ideal for making cuttings. A cutting from 2 to 4 in. long seems to be best. As soon as the cuttings are made they should be placed in cool water. If aphids are present, the cuttings should be placed in a 1 to 500 or 1 to 800 solution of nicotine sulphate in water before planting. Clean sand is the best soil material in which to root such cuttings. The sand should be firmly packed and watered and the cuttings inserted. They should then be firmed and watered to wash the sand down around them. The bed should be lightly shaded for a few days to prevent wilting. Wilted cuttings generally die but if they root the resulting plants are stunted. Syringing on warm days will help to keep the cuttings fresh. A temperature of 50° F is sufficient, but quicker rooting is obtained if 60° F is maintained.

When the roots are about $\frac{1}{2}$ in. long the plants should be potted in a fibrous loam soil. If allowed to remain too long in the cutting bed, they become hard and are not responsive to good culture. The plants are usually ready for their permanent quarters by early June or July. A good fibrous, well drained loam is the ideal soil medium for chrysanthemums. If this soil is packed before planting or directly afterwards, the new growth becomes firmer and the internodes shorter. Newly set plants should be watered only lightly as wet soil is unfavourable for their growth. The tops of the plants may, however, be syringed often to keep them fresh. The planting distances vary with the different types. Commercial growers vary the planting of the large flowering chrysanthemums as follows: 6 in. by 6 in., 7 in. by 8 in., $7\frac{1}{2}$ in. by 8 in., 10 in. by 10 inches. Pompons are planted 12 in. by 12 in. and 12 in. by 15 in. inside, while outdoors 15 in. by 15 in. and 18 in. by 18 in. is the general practice.

As soon as the plants are placed they should be staked and tied. The tying should be done as the plant grows so the stem will remain straight. When the stem becomes 6 in. long the plant should be "topped" (top pinched out), if more than one stem is desired. Topping should continue for small flowered plants until August. Watering, syringing and tying are of chief importance during the summer months. The plants should be kept as cool as possible by spraying and syringing and by wetting the walks. In the late summer and early fall "disbudding" becomes a factor. The first bud to appear is generally the crown bud. This bud will flower early and give a large flower, but the shape, colour and habit are not as desirable for commercial use as are flowers from lateral buds. The crown bud is surrounded by vegetative shoots, one of which may be saved to produce the desirable flower bud. The terminal bud of the final shoot is surrounded by other buds which should be removed if only one large flower is desired.

If the soil is a good composted fibrous loam, no fertilizer should be given until the bud is selected. Thereafter manure water, a commercial chrysanthemum fertilizer, should be given once a

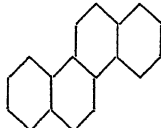

week until the buds show colour. Continued use of any fertilizer, especially those that are too strong, will cause the flowers to "blast" and "burn." The foregoing cultural directions apply equally as well to the chrysanthemums in the garden. Systematic fumigation and spraying with effective fumigants, insecticides and fungicides and the propagation of clean stock, are the greatest factors in the prevention and control of pests. Upwards of 500 named varieties of the chrysanthemum are listed in dealers' catalogues and horticultural works, and new forms are constantly being produced.

For more extensive details, see L. H. Bailey, *The Standard Cyclo-pedia of Horticulture* (1914-17; rev. ed., 1922); for list of recognized American varieties, see F. L. Olmsted, F. V. Coville and H. P. Kelsey, editors, *Standardized Plant Names* (Salem, Mass., 1924). See also E. A. White, *The Chrysanthemum and Its Culture* (1930). (H. O. Y.)

CHRYSANTHIUS, Greek philosopher of the 4th century A.D. He was a pupil of Aedesius and an exponent of the mystical side of Neoplatonism (*q.v.*). Invited by the emperor Julian to assist in the scheme for the revival of Hellenism, he declined, probably foreseeing its failure. As high-priest of Lydia he kept the respect of Christians and pagans alike.

CHRYSELEPHANTINE, the architectural term given to statues which were built up on a wooden core, with ivory representing the flesh and gold the drapery (Gr. χρυσός, gold, ἐλέφας, ivory). The two most celebrated examples are those by Pheidias, the statue of Athena in the Parthenon and of Zeus in the temple at Olympia.

CHRYSENE, a hydrocarbon discovered by Laurent in the high boiling point fractions of coal tar distillate, is produced in small quantity in the distillation of amber, or on passing the vapour of phenyl-naphthyl-methane through a red-hot tube. When impure, it is of a yellow colour; hence its name (χρύσεος, golden

yellow). Chrysene, $C_{18}H_{12}$,  crystallizes in colour-

less plates or octahedra (from benzene), which exhibit a violet fluorescence, and melt at 250°C and boil at 448°C . Chromic acid in glacial acetic acid solution oxidizes it to chrysoquinone $C_{18}H_{10}O_2$, which when distilled with lead oxide gives chrysoketone $C_{17}H_{10}O$.

BIBLIOGRAPHY.—A. E. Everest, *The Higher Coal-tar Hydrocarbons* (1927).

CHRYSIPPUS (c. 280-206 B.C.), Greek philosopher, third leader of the Stoics, born at Soli, Cilicia (Diog. Laert. vii. 179). He came to Athens and studied possibly under Zeno, certainly under Cleanthes. It is said also that he became a pupil of Arcesilaus and Lacydes, heads of the middle academy. The comprehensiveness of his early studies left its mark on his philosophic work. His chief fame rested on his controversies in the academy, for which he was called "the column of the portico." Diogenes Laertius says "without Chrysippus there had been no Porch." Of the 750 treatises with which he is credited only fragments survive. The style is said to have been crabbed, the argument lucid.

Brehier, *Chrysippe* (Les Grands philosophes, Paris, 1910). See also STOICS.

CHRYSOBERYL, a yellow or green gem-stone, remarkable for its hardness, being exceeded in this respect only by the diamond and corundum. The name suggests that it was formerly regarded as a golden variety of beryl. Its composition is BeAl_2O_4 , or $\text{BeO} \cdot \text{Al}_2\text{O}_3$. It is yellow or pale green, occasionally passing into shades of dark green and brown. Chrysoberyl is often mistaken by its colour for chrysolite (*q.v.*), and has indeed been termed

oriental chrysolite, but it is a much harder and denser mineral. As the two stones are apt to be confounded, it may be convenient to contrast their chief characters:

| | Chrysoberyl. | Chrysolite. |
|--------------------------------|---------------------------|---------------------------|
| Hardness | 8.5 | 6.5 to 7 |
| Specific gravity | 3.65 to 3.75 | 3.34 to 3.37 |
| Chemical composition | BeAl_2O_4 | Mg_2SiO_4 |

Chrysoberyl is not infrequently cloudy, opalescent and chatoyant, and is then known as "cymophane" (Gr. κύμα, cloud). The cloudiness is referable to the presence of multitudes of microscopic cavities. Some of the cymophane, when cut with a convex surface, forms the most valuable kind of cat's-eye (see CAT'S-EYE). A remarkable dichroic variety of chrysoberyl is known as alexandrite (*q.v.*).

Most chrysoberyl comes from Brazil, chiefly from the district of Minas Novas in the State of Minas Geraes, where it occurs as small water-worn pebbles. The cymophane is mostly from the gem-gravels of Ceylon. Chrysoberyl is known as a constituent of certain kinds of granite, pegmatite and gneiss. In the United States it occurs at Haddam, Conn.; Greenfield Centre, near Saratoga Springs, N.Y.; Greenwood, Me. and in Manhattan island. It is known also in the province of Quebec, Canada, and has been found near Gwelo in Rhodesia.

CHRYSOCOLLA, a hydrous copper silicate occurring as a decomposition product of copper ores. It is never found as crystals, but always as encrusting and botryoidal masses. It is green or bluish-green in colour, and often has the appearance of opal or enamel, being translucent and having a conchoidal fracture with vitreous lustre; sometimes it is earthy in texture. Not being a definite crystallized substance, it varies widely in chemical composition, the copper oxide (CuO), for example, varying in different analyses from 17 to 67%. The hardness (2-4) and sp. gr. (2.0-2.8) are also variable. The mineral occurs in the upper parts of veins of copper ores, and has resulted from their alteration by the action of waters containing silica in solution. Pseudomorphs of chrysocholla after various copper minerals (*e.g.*, cuprite) are not uncommon. It is found in most copper mines. The name chrysocholla (from χρυσός, gold and κόλλα, glue) was applied by Theophrastus and other ancient writers to materials used in soldering gold, one of which, from the island of Cyprus, may have been identical with the mineral now known by this name. Borax, which is used for this purpose, has also been called chrysocholla.

CHRYSLITE, a transparent green gem-stone. The name chrysolite, meaning "golden stone" (χρυσός and λίθος), has been applied to various yellowish gems, notably to topaz, to some kinds of beryl and to chrysoberyl. The true chrysolite of the modern mineralogist is a pale green olivine (*q.v.*).

CHRYSOLOGUS, PETER (c. 405-c. 450), bishop of Ravenna, was born at Imola and died at Ravenna. As bishop, he opposed Arianism, Pelagianism and Eutychianism. Of the works printed in Migne's *Patrol. Lat.*, vol. lli., only about 100 sermons are genuine.

See F. V. Stablewski, *Der heilige Kirchenvater P. von Ravenna* (1871), F. J. Peters, *Petrus Chrysologus als Homilet* (Cologne, 1918).

CHRYSOLORAS, MANUEL [or EMMANUEL] (c. 1355-1415), one of the pioneers in spreading Greek literature in the West, was born at Constantinople. He was a pupil of Gemistus (*q.v.*). In 1393 he was sent to Italy by the emperor Manuel Palaeologus to implore the aid of the Christian princes against the Turks. At the invitation of the magistrates of Florence he became about 1395 professor of the Greek language in that city, where he taught for three years. He became famous as a translator of Homer and Plato. Later, after visiting Milan, Pavia and Venice, he was invited to Rome. In 1408 he was sent to Paris on an important mission from the emperor Manuel Palaeologus. In 1413 he went to Germany on an embassy to the emperor Sigismund, the object of which was to fix a place for the assembling of a general council. It was decided that the meeting should take place at Constance; and Chrysoloras was on his way thither, having been chosen to represent the Greek Church,

when he died suddenly on April 15, 1415. Only two of his works have been printed, his *Erotemata* (published at Venice in 1484), which was the first Greek grammar in use in the West, and *Epistolae III. de comparatione veteris et novae Romae*.

JOHN CHRYSOLORAS, a relative of the above, who, like him, had studied and taught at Constantinople, and had then gone to Italy, shared Manuel's reputation as one of those who spread the influence of Greek letters in the West. His daughter married Filelfo (*q.v.*).

CHRYSTOPRASE is a transparent variety of crypto-crystalline silica of an apple-green colour (Gr. χρυσός, gold and πράσιν, leek), the latter being due to the presence of nickel, probably in the form of hydrous silicate. A very similar artificial gem may be prepared by immersing chalcedony in solutions of nickel salts. On exposing a natural chrystoprase to light or heat its colour becomes paler, though this may be restored by placing the stone in a damp medium. It is surprising that the colour of the natural gem should be susceptible to the action of light and heat, whilst the artificial product is quite unaffected. (*Precious Stones*, by Max Bauer; trans. L. J. Spencer, 1904.)

CHRYSOSTOM (ST. JOHN CHRYSOSTOM) (Χρυσόστομος, golden-mouthed) (A.D. 345–407), the most famous Greek Father, was born at Antioch about A.D. 345. At the school of Libanius, the sophist, he gave early indications of his mental powers and love of classical culture. On being baptized (*c.* 370) by Meletius, bishop of Antioch, he retired to the desert, where for ten years he led a life of asceticism and study. Illness compelled him to return to the world, and in 381 he was ordained deacon, and in 386 priest. He won great reputation by his preaching at Antioch, especially by his homilies on *The Statues*, delivered when the people feared the consequences of the destruction of the statues of the emperor Theodosius during a riot.

On the death of Nectarius, Chrysostom was appointed bishop of Constantinople (398). In this capacity he won the love of the people by his eloquent and devout homilies and by the application of his ample revenues to the establishment of hospitals. But his reforming zeal also made him many enemies. The clergy were forbidden to keep lay sisters as servants, aimless monks were confined to their monasteries, and the extravagances of the court were strongly denounced. His enemies found a pretext for revenge in the shelter which he had given to four Nitrian monks who had been excommunicated by their bishop, Theophilus of Alexandria. Theophilus was invited to Constantinople (403) and charging Chrysostom with Origenism, thrice summoned him to appear before a synod. He refused to appear and finally was declared deposed, arrested and exiled. The threats of the people, however, led the empress Eudoxia to recall him. Shortly afterwards his denunciation of the honours addressed to a statue of the empress almost within the precincts of St. Sophia led to the calling of a second council, which again deposed him (404) for having resumed his functions without its permission. The people fired the cathedral and the senate-house, but Chrysostom was hurried away to Cucusus (Cocysus) among the ridges of Mount Taurus. His correspondence with the different churches and the recognition of his orthodoxy by Pope Innocent I. and the emperor Honorius caused the emperor Arcadius to order his removal to the extreme desert of Pithyus. He died on the way at Comana in Pontus in 407. His exile gave rise to a schism and the Johannists (as they were called) only returned to communion with the bishop of Constantinople after the relics of the saint were brought back (437) and the emperor had publicly implored divine forgiveness. The feast of St. John Chrysostom falls on Nov. 13 in the Greek Church and on Jan. 27 in the Latin Church.

He elevates the ascetic element in religion and stresses the importance of knowing the Scriptures. In exegesis he is pure Antiochene, basing his expositions upon thorough grammatical study and not on the allegorical interpretation of Origen and the Alexandrian school. His writings contain the germ of later Eucharistic teaching and the invocation of the saints, but give no direct expression of the primacy of the pope or the necessity of private confession. As early as 425 Chrysostom was cited by the Greeks and Latins as a great authority.

His voluminous works include the early-monastical treatises, including *On Priesthood*, the many homilies and commentaries written during his priesthood and episcopate, the best known being those *On the Statues* and on *Genesis*, *Psalms*, *Matthew* and *Romans*, and the letters which belong to the time of his exile and are valuable sources of history.

The best edition is that of Migne (*Patrol. Graec.* xlvii.–lxiv.) but many of the treatises have been edited more recently. English translations of some of the homilies and commentaries are in the Oxford Library of the Fathers. The most valuable authorities for his life are the ecclesiastical histories of Palladius, Socrates, Sozomen and Theodoret.

Baur, *S. Jean Chrysostome et ses oeuvres* (Louvain, 1907); J. M. Vance, *Beiträge zur Byzantinischen Kulturgeschichte aus den Schriften des Chrysostom* (Jena, 1907); A. Harnack, *Hist. of Dogma* iii. and iv.

CHRYSTOLE, a variety of serpentine, a hydrous silicate of magnesia, which is characterized by a fine, more or less silklike fibrous structure; this is the principal fibrous mineral used in commerce under the name asbestos (*q.v.*). (The name is derived from the Greek χρυσός, gold and τριχός, down or hair, literally hair of gold.)

CHUB (*Leuciscus cephalus*), a Cyprinid fish distinguished from others of the family in English rivers by the broad head and strong jaws and by feeding to a considerable extent on little fish. In England a length of 2 ft. and a weight of 8 lb. is reached, but on the Continent 12 lb. In America the name is applied to other large-headed Cyprinids, *e.g.*, the river chub (*Hybopsis kentuckiensis*) and the silver chub (*Semotilus corporalis*).

CHUBB, CHARLES (d. 1845), English locksmith, started a hardware business at Winchester, subsequently removing to Portsmouth. Here he improved on the "detector" lock originally patented in 1818 by his brother, Jeremiah Chubb. He soon moved to London and then to Wolverhampton, where he employed two hundred workers. In 1835 he patented a process intended to render safes burglar-proof and fireproof, and eventually established a large safe-factory in London. He died on May 16, 1845, and was succeeded in the business by his son, John Chubb (1816–72), who patented various improvements in the products of the firm.

CHUBB, THOMAS (1679–1746), English deist, was born at East Harnham, near Salisbury, on Sept. 29, 1679. The son of a maltster, he was apprenticed to a glove-maker and subsequently worked for a tallow-chandler. Later he lived for some years in the house of the master of the rolls, Sir Joseph Jekyll, apparently as a servant of some kind. He died in Salisbury on Feb. 8, 1746. He appeared as an author during the Arian controversy with an essay, *The Supremacy of the Father Asserted*, published on Whiston's authority in 1715. Mainly interesting as showing the spread of rationalism in the popular mind of the period, he was regarded by Voltaire as one of the most logical of his school. (See *DEISM*.) His chief works are *Discourse concerning Reason* (1731); *True Gospel of Jesus Christ* (1739); and *Posthumous Works* (1748).

CHUBUT, a territory of the southern Argentine Republic, part of what was formerly called Patagonia, bounded north by Rio Negro, south by Santa Cruz, east by the Atlantic and west by Chile. Pop. (1926) 32,885; area, 93,427 sq.m. Except for the valleys in the Andean foot-hills, which are fertile and well forested, and the land along the banks of the Chubut river, which flows entirely across the territory from the Andes to the Atlantic, the country is a steppe land covered with scanty dwarfed vegetation, with occasional shallow saline lakes. The larger rivers are the Chubut and the Senguerr, the latter flowing into Lake Colhuapi. There are a number of large lakes among the Andean foot-hills, the best known of which are Fontana, La Plata and General Paz, and, in the interior, Colhuapi or Colhué and Musters, the latter named after the English naval officer who traversed Patagonia in 1870. Petroleum was found at Comodoro Rivadavia, in the southern part of the territory, toward the close of 1907, at a depth of 1,768 ft. and is being exploited. Chubut is known chiefly by the Welsh colony near the mouth of the Chubut river and its branch,

the 16th of October colony, farther up the river. The chief town of the Welsh, Rawson, is the capital of the territory, and Port Madryn on Bahía Nueva is its best port. Other colonies have been founded in the fertile valleys of the Andean foot-hills, but their growth is greatly impeded by lack of transportation facilities. (See PATAGONIA.)

CHUCK, a device for holding work in a lathe (*q.v.*) or a drill (see DRILL and BORING) and consisting essentially of three or four converging jaws.

CHUDE, a tribal name used in both a special and a general sense. (1) It was the name given by the Russians to certain Estonian tribes with whom they came in contact as they spread gradually over their present empire. It would seem that the northern Chudes are the Vepsas. (2) As the Russians advanced eastwards they extended the name to various tribes whom they considered to be like the Estonians, and in popular use it has come to be applied to any ancient non-Russian people in Siberia, at least as far east as the Altai.

CHUGUYEV, a town in the Kharkov county of the Ukrainian S.S.R., on the right bank of the river Donetz, where the railway linking Kharkov to Kupiansk crosses the river. Lat. 49° 49' N. Long. 36° 41' E. Pop. (1926) 13,311.

CHUKCHI, CHANKTOS ("Men") or TUSKI ("Brothers" or "Confederates"), a Mongoloid people inhabiting the north-easternmost portion of Siberia on the shores of the Arctic Ocean and Bering Sea. They are settled in small groups along the Arctic coast between the Bering Strait and the Kolyma river, or wander as far inland as the Anadyr basin. They are tall, lean, with somewhat irregular features and round-headed. The nose is set deep between the cheeks. The lips are thick, and the brow low. The hair is coarse, lank and black. They are classed as Nearetic.

The Chukchi are divided into the "Fishing Chukchi," who have settled homes on the coast, and the "Reindeer Chukchi," who are nomads. The latter breed reindeer in large herds, live on the flesh and milk, and are generally fairly prosperous; while the fishing folk are very poor, begging from their richer kinsfolk hides to make tents and clothes. They kill off the old and infirm. They believe in a future life, but only for those who die a violent death. It is thus an act of filial piety for a son to kill his parent or a nephew his uncle. This custom is known as *kamitok*. The Chukchi sacrifice animals to the spirits of the rivers and mountains, and also practise Shamanism. The use of drums in these rites is general. They are polygamous, but the women are treated kindly. The children are specially petted. Chukchi women are often tattooed with two black-blue convex lines running from the eye to the chin. Since their adoption of Christianity the men sometimes have a Latin cross tattooed on their chins. The Chukchi burn their dead or expose them on platforms to be devoured by ravens.

See Harry de Windt, *Through the Gold Fields of Alaska to Bering Strait* (1898); Dittmar, "Über die Koriaken u. ihnen nahe verwandten Tchouktchen," in *Bul. Acad. Sc. (St. Petersburg)*, xii. p. 99; Hooper, *Ten Months among the Tents of the Tuskis*; W. H. Dall, *Contributions to North American Ethnology*, vol. i. (1877); M. Czaplicka, *Aboriginal Siberia* (1914).

CHULALONGKORN, PHRA PARAMINDR MAHA (1853-1910), king of Siam, eldest son of King Maha Mongkut, was born on Sept. 21, 1853, and succeeded his father on the throne on Oct. 1, 1868. The young king, who had according to custom been brought up in a Buddhist monastery, again retired into seclusion until he came of age in 1873, the government being entrusted to a regency. He then took the step, unprecedented for an eastern Asiatic potentate, of travelling outside his dominions, in India and the Dutch East Indies. The fruits of his appreciation of foreign institutions appeared in the reforms which he instituted in Siam: the abolition of slavery, the simplification of court etiquette, the grant of liberty of conscience, the erection of schools and hospitals, and the further development of the army and navy. He established a standard coinage, postal and telegraph services, and arranged for the policing, sanitation, and lighting of Bangkok. Several of his sons, including the Crown Prince, were educated in England, and he himself visited Europe in 1897. He died at Bangkok on Oct. 23, 1910.

CHUMASH, the natives of the Santa Barbara coast and islands, California. When discovered by Cabrillo in 1542, and missionized from 1771 on, they numbered perhaps 8,000-10,000, but were virtually extinct by 1900. They made sea-going plank canoes, harpoons and spear-throwers, many shell ornaments and fine baskets. Technologically they ranked with their neighbours, the Gabrielino, at the head of all Californian tribes. Their society and religion are almost unknown, but may be assumed as similar to those of the Gabrielino.

CHUMBI VALLEY, a valley connecting Tibet (*q.v.*) with the frontier of British India. Lying on the southern slopes of the Himalayas at an altitude of about 9,500 ft. above the sea, the valley is wedged in between Bhutan and Sikkim, and does not belong geographically but only politically to Tibet. This was the route by which the British mission of 1904 advanced. The valley is of great natural beauty, but only sparsely cultivated on small flats by the river. The summer months, though not hot, are relaxing and enervating.

CHUNAR, a town and ancient fortress of India, in the district of Mirzapur, in the United Provinces, situated on the south bank of the Ganges. Pop. (1921) 6,960. The fort occupies a conspicuous site on the summit of an abrupt rock which commands the river. It was at one time a place of great strength, and still contains the remains of a Hindu palace with some interesting carvings. The town, which consists of one or two straggling streets, was once a European settlement, for the invalid or veteran battalion of the East India Company's army. In the church, the school, some ruinous houses, and the graveyards, are traces of that colony of war-worn exiles. The chief industry is now the excellent building stone which is found in the neighbourhood.

In 1530 Chunar became the residence of Shere Shah the Afghan, and forty-five years later was recovered by the emperor Akbar after sustaining a siege of six months. It fell into the hands of the English under General Carnac in 1763 after a prolonged resistance. A treaty with the nawab of Oudh was signed here by Warren Hastings on behalf of the East India Company in Sept. 1781, and for a time it enjoyed a military importance as the frontier post of the company's jurisdiction.

CHUNCHO, a tribe of South American Indians, living in the forests east of Cuzco, central Peru. Chuncho has also been used to describe one of three aboriginal stocks of Peru, the others being Quichua and Aymara.

CHUNGKING, the treaty port and commercial emporium of the isolated but important and densely peopled Inland Basin of Szechwan in West China (situation, 29° 32' N., 106° 50' E.). It is built on a rocky peninsula at the confluence of the Kialing-kiang, the most easterly of the great rivers draining the Red Basin, with the Yangtze-kiang, the arterial line of communication in Middle China. Chungking is therefore the natural gateway through which Szechwan communicates with the rest of China and the ocean. Moreover it gathers up the trade of E. Tibet and of much of the north of Kweichow and Yunnan which finds a natural outlet to the Yangtze, although in the case of the last-named province the French railway from Yunnan-fu to the coast of Tongking is a distinct competitor. Chungking therefore exports not only the agricultural products—silk, tea and rice—of the Basin of Szechwan but also the pastoral products—skins, hides and wool—of its mountain borders. Although the collecting centre *par excellence* for West China, Chungking does little direct trade with the coast. Hankow, the focus of the Central (Hupeh) Basin nearer the sea, constitutes a later collecting centre for a wider area. The flat-bottomed steamboats, specially built to negotiate the Yangtze Gorges, run only between Chungking and Ichang, another trans-shipment point between Chungking and Hankow. The first steamboat reached Chungking in 1898 and a regular service through the Gorges is now maintained except during low-water in winter. The more rapid transport offered by steamboats is making junk traffic through the Gorges less and less profitable. Steam-launches now ply on the Yangtze above Chungking as far as Suifu and during the high-water of summer as far as Kiating on the Min river. Chungking, however, still

remains a great centre for junk traffic, which must always carry the local river-borne trade. The total trade of Chungking has continued to increase steadily from Hk. Tls. 10,780,389 in 1894 (it was opened to foreign trade in 1891) to Hk. Tls. 73,757,098 in 1926.

A railway connecting Chungking with Chêngtu, the regional centre of the Red Basin and the capital of Szechwan, has long been contemplated and is one of the most important items in the railway programme of China. The population of Chungking is approximately 600,000. (P. M. R.)

CHUPATTY. An Anglo-Indian term for an unleavened cake of bread. The word represents the Hindustani *chapati*, and is applied to the usual form of native bread, the staple food of upper India. The chupatty is generally made of coarse wheaten flour, patted flat with the hand, and baked upon a griddle. In 1857, chupatties were circulated as a sign of discontent.

CHUPRIYA (sometimes written Tyupriya; Croatian *Cuprija*), the capital of the Morava department of Serbia, Yugoslavia. The old name was Korea Margi. (Pop., 1921, 4,917.) The town is on the railway from Belgrade to Nish, and on the Morava, which is navigable up to this point by small sailing vessels. A light railway runs to Senje, which has lignite and other collieries that were, however, very seriously damaged in the World War. Some of the finest Serbian cattle are bred in the neighbouring lowlands, and the town has a large sugar beet factory and a considerable trade in plums and farm produce. A Government nursery for mulberry trees has been started, and it is hoped by the free distribution of silkworm eggs to revive sericulture, which flourished in the middle ages but died down under Turkish rule. There is a Government stud farm in the district. In the World War Chupriya was the central ammunition depôt of the Serbian army. Cloth is woven, and there are glass works at Paracin, 5m. S.; while Jagodina, 8m. W. by N., is an important market town. Both are connected with Chupriya by rail and road.

The 14th-century Ravanitsa monastery, with a ruined fort and an old church (their walls and frescoes pitted by Turkish bullets) is about 7m. distant. Legend says that here the Serbian tsar Lazar (1374-89) was visited by an angel who bade him choose between an earthly and a heavenly crown. In accordance with his choice Lazar fell fighting at the battle of Kosovo. He was buried at Ravanitsa, but his body was afterwards removed. His crucifix is treasured among the monastic archives, which also contain a charter signed by Peter the Great of Russia (1672-1725). Manasia (*Manasiya*), the still more celebrated foundation of Stephen, the son and successor of Lazar, lies 12m. N. of Ravanitsa. Built in a cleft among the hills, this monastery is enclosed in a fortress, whose square towers, and curtain without loopholes or battlements, remain largely intact. Within the curtain stand the monastic buildings, a large garden and a cruciform chapel, with many curious old stone carvings, half hidden beneath whitewash. Numerous gifts from the Russian court, such as gospels lettered in gold and silver relief, and jewelled crucifixes, are preserved on the spot, but the valuable library was removed in the 15th century to the monastery of Hilendar on Mt. Athos.

CHUQUET, NICOLAS (1445-1500), French mathematician, was born at Paris. He studied and qualified in medicine, probably at Lyons. In 1484 he wrote a work on arithmetic, *Triparty en la science des nombres*. This was circulated in manuscript form and was first printed in 1880. The first part deals with rational numbers, the second with irrational numbers and square roots, and the third part is a study of equations. The *Triparty* was very largely used and its influence can be traced in the *Arithmétique* of de la Roche.

See A. Marre, "Notice sur Nicolas Chuquet et son Triparty," *Bulletino Boncompagni* xiii.

CHUQUISACA, a department of S.E. Bolivia. It lies partly upon the eastern plateau of Bolivia and partly upon the great plains of the upper La Plata basin; area, 36,132 sq.m. The Pilcomayo, a large tributary of the Paraguay, crosses N.W. to S.E. the western part of the department. The climate of the lowlands is hot, humid and unhealthy, but that of the plateau is salubrious, though subject to greater extremes in temperature. The seasons

are sharply divided into wet and dry, the eastern plains becoming great lagoons during the wet season, and parched deserts during the dry. The mineral resources are important, but are less developed than those of Potosí and Oruro. Grazing is the principal industry of the plains, and cattle, sheep, goats and llamas are raised and cereals grown in the fertile valleys of the plateau. Rough highways connect Chuquisaca with its neighbours on the N. and W., and pack animals are the common means of transporting merchandise. The first railway in the department running from Potosí to Sucre was near completion in 1927. The population was estimated at 333,226 in 1915, and is largely composed of Indians and mestizos. The plateau Indians are generally Aymaras, but on the eastern plains there are considerable settlements of partly civilized Chiriguano, of Guaraní origin. The department is divided into five provinces, the greater part of the lowlands being unsettled and without effective political organization. Its principal towns are Sucre, the capital, Camargo, Padilla and Yotala.

CHUR, the capital of the Swiss canton of the Grisons (Fr. *Coire*, Ital. *Coira*). It lies 1,950 ft. above sea-level on the valley-floor of the Vorder Rhein in the angle between the Plessur and the Rhine, and is overshadowed by the Mittenberg and Pizokel, hills that guard the entrance to the deep-cut Schanfigg (Plessur) valley. Pop. (1920) 15,600, with 12,644 German-speaking, 1,871 Romansch-speaking and 943 Italian-speaking. Protestants numbered 9,783, and Roman Catholics 5,733. The old city is on the west, and includes the cathedral church of St. Lucius (traditionally a 2nd-century British king), which was built between 1178 and 1282, on the site of an older church. Opposite is the Bishop's Palace, and not far off is the Episcopal Seminary (built on the ruins of a 6th-century monastic foundation). The Raetian Museum contains a great collection of objects relating to Raetia. Chur is 74 m. by rail from Zürich: it is the meeting-point of routes from Italy over many Alpine passes (the Lukmanier, the Splügen, the San Bernardino) and is the centre of an active trade, particularly in wine from the Valtellina. Electric trains run to Davos, St. Moritz, Arosa and Andermatt.

The episcopal see is first mentioned in 452, but probably existed a century earlier. The bishop soon acquired great temporal powers, and became a prince of the Empire in 1170. In 1392 he became head of the league of God's House (originally formed against him in 1367), one of the three Raetian leagues, but in 1526, after the Reformation, lost his temporal powers, having fulfilled his historical mission (see GRISONS). The bishopric still exists, with jurisdiction over the Cantons of the Grisons, Glarus, Zürich, and the three Forest Cantons, as well as over Liechtenstein. The guild constitution of the city of Chur lasted from 1465 to 1839.

CHURCH, SIR ARTHUR HERBERT (1834-1915), British chemist, was born on June 2, 1834, in London. He was educated at the Royal College of Chemistry in London and at Oxford. In 1863 he was appointed professor of chemistry at the Royal Agricultural college, Cirencester, and during this period Church studied chemical problems connected with agriculture. He was a man of wide and varied tastes, and applied chemistry to the subjects in which he was interested, such as mineralogy (he discovered a new mineral, Churchite), archaeology and chiefly painting. In 1879 Church was appointed professor of chemistry at the Royal Academy of Arts; he retired from this post in 1911. During this period he worked on the chemistry of painting and his book, *The Chemistry of Paints and Painting* (1890), has run into many editions and has been translated into German.

He was an authority on precious stones and porcelain; he left instructions to his wife that various collections of curios and antiques were to go to the Ashmolean Museum at Oxford and his cut precious stones to the British Museum. He died in London on May 31, 1915.

Some of his works are *Handbook of Precious Stones* (1883); *English Earthenware* (1884); *English Porcelain* (1885); *Food Grains of India* (1886); *Josiah Wedgwood* (1894), and *The Conservation of Historic Buildings and Frescoes* (1907).

CHURCH, FREDERICK EDWIN (1826-1900), American landscape painter, was born at Hartford (Conn.) on May 4, 1826. He was a pupil of Thomas Cole at Catskill (N.Y.), where his first pictures were painted. Developing unusual technical dexterity, Church from the beginning sought for his themes such marvels of nature as Niagara Falls, the Andes, and tropical forests—he visited South America in 1853 and 1857—volcanoes in eruption, and icebergs, the beauties of which he portrayed with great skill in the management of light, colour, and the phenomena of rainbow, mist and sunset, rendering these plausible and effective. In their time these paintings awoke the wildest admiration and sold for extravagant prices, collectors in the United States and in Europe eagerly seeking them, though their vogue has now passed away. In 1849 Church was made a member of the National Academy of Design. His "Great Fall at Niagara" (1857) is in the Corcoran Art Gallery, Washington (D.C.), and a large "Twilight" is in the Walters Gallery, Baltimore (Md.). Among his other canvases are "Andes of Ecuador" (1855), "Heart of the Andes" (1859), "Cotopaxi" (1862), "Jerusalem" (1870), and "Morning in the Tropics" (1877). He died on April 7, 1900, at his house on the Hudson river above New York city, where he had lived and worked for many years. He was the most prominent member of the "Hudson river school" of American artists.

CHURCH, GEORGE EARL (1835-1910), American geographer, was born in New Bedford (Mass.), on Dec. 7, 1835. He was educated as a civil engineer, and was early engaged on the Hoosac tunnel. In 1858 he joined an exploring expedition to South America. During the American Civil War he served (1862-65) in the Army of the Potomac, rising to the command of a brigade and the rank of colonel; and in 1866-67 he was war correspondent of the *New York Herald* in Mexico. He explored the Amazon (1868-79), and gradually became the leading authority on that region of South America. In 1880 he was appointed U.S. commissioner to report on Ecuador, and in 1895 visited Costa Rica to report on its debt and railways. He wrote extensively on South and Central American geography, and became a vice-president of the Royal Geographical Society (London), and in 1898 president of the geographical section of the British Association.

CHURCH, SIR RICHARD (1784-1873), British military officer and general in the Greek army, was the son of a Quaker, Matthew Church of Cork. He was born in 1784, and at the age of 16 ran away from home and enlisted in the army. For this violation of its principles he was disowned by the Society of Friends, but his father bought him a commission in the 13th (Somersetshire) Light Infantry. He served in the demonstration against Ferrol, and in the expedition to Egypt under Sir Ralph Abercromby in 1801. He accompanied the expedition which landed in Calabria, and fought a successful battle against the French at Maida on July 6, 1806. In the summer of 1809 Church sailed with the expedition sent to occupy the Ionian islands. Here he formed a Greek regiment in English pay. It included many of the men who were afterwards among the leaders of the Greeks in the War of Independence. Church drew up a report on the Ionian islands for the Congress of Vienna, in which he advocated the retention of the islands under the British flag and the permanent occupation by Great Britain of Parga and of other formerly Venetian coast towns on the mainland, then in the possession of Ali Pasha of Iannina. In 1817 he entered the service of King Ferdinand of Naples as lieutenant-general, with a commission to suppress the brigandage then rampant in Apulia. In 1820 he was appointed governor of Palermo and commander-in-chief of the troops in Sicily. The revolution which broke out in that year led to the termination of his services in Naples.

In 1827 Church became commander-in-chief of the Greek army. The rout of his army in an attempt to relieve the acropolis of Athens, then besieged by the Turks, proved that it was incapable of conducting regular operations. The acropolis

capitulated, and Sir Richard (he had been knighted by George IV.) turned to partisan warfare in western Greece. Here his activity had beneficial results, for it led to a rectification in 1832, in a sense favourable to Greece, of the frontier drawn by the Powers in 1830 (see his *Observations on an Eligible Line of Frontier for Greece*, 1830). Church had, however, surrendered his commission, as a protest against the unfriendly Government of Capo d'Istria, on Aug. 25, 1829. He lived for the rest of his life in Greece, was created general of the army in 1854, and died at Athens on March 30, 1873.

See *Sir Richard Church*, by Stanley Lane Poole (1890); Z. D. Feniman, *Some English Philhellenes* (1917); *Sir Richard Church in Italy and Greece*, by E. M. Church (Edinburgh, 1895), based on family papers (an Italian version, *Brigantaggio e società segrete nelle Puglie, 1817-1828*, executed under the direction of Carlo Lacaita, appeared at Florence in 1899). The ms. correspondence and papers of Sir Richard Church, in 29 vols., now in the British Museum (add. mss. 36,543-36,571), contain invaluable material for the history of the War of Greek Independence, including a narrative of the war during Church's tenure of the command, which corrects many errors in the published accounts and successfully vindicates Church's reputation against the strictures of Finlay, Mendelssohn-Bartholdy and other historians of the war (see *Cam. Mod. Hist.* x. p. 804).

CHURCH, RICHARD WILLIAM (1815-1890), English divine, son of John Dearman Church, brother of Sir Richard Church (q.v.), a merchant, was born at Lisbon on April 25, 1815, his early years being mostly spent at Florence. He went up to Wadham college, Oxford, in 1833, took first-class honours in 1836, and in 1838 was elected fellow of Oriel. He was appointed tutor of Oriel in 1839, and was ordained the same year. He was an intimate friend of J. H. Newman at this period, and closely allied to the Tractarian party. In 1841 No. 90 of *Tracts for the Times* appeared, and Church resigned his tutorship. In 1844-45 he was junior proctor, and in that capacity, in concert with his senior colleague, vetoed a proposal to censure Tract 90 publicly. In 1846 Church, with others, started *The Guardian* newspaper, and he was an early contributor to *The Saturday Review*. He accepted in 1852 the small living of Whatley in Somersetshire, near Frome. In 1869 he refused a canonry at Worcester, but in 1871 he accepted, most reluctantly (calling it "a sacrifice *en pure perte*"), the deanery of St. Paul's, to which he was nominated by W. E. Gladstone. Dean Church died on Dec. 9, 1890.

His chief pub. works are a *Life of St. Anselm* (1870); the lives of *Spenser* (1879) and *Bacon* (1884) in Macmillan's "Men of Letters" series; an *Essay on Dante* (1878); *The Oxford Movement* (1891), together with many other vols. of essays and sermons. A coll. of his journalistic arts. was pub. in 1897 as *Occasional Papers*.

See *Life and Letters of Dean Church*, by his daughter, M. C. Church (1895); memoir by H. C. Beeching in *Dict. Nat. Biog.*; and D. C. Lathbury *Dean Church* (1907).

CHURCH. The word church refers both to the Christian religious community and to the building used for Christian worship. This article, after discussing the etymology of the word itself, will deal separately with these two subjects.

Etymology of the Word Church.—According to most authorities, the word is derived from the Gr. *κυριακὸν* (*δῶμα*), "the Lord's (house)," and is common to many Teutonic, Slavonic and other languages, under various forms—e.g., Scottish *kirk*, Ger. *kirche*, Swed. *kirka*, Dan. *kirke*, Russ. *tserkov*, Bulg. *cerkova*, Czech. *cirkev*, Finn. *kirkko*, etc. The word was originally applied to the building used for Christian worship, and subsequently extended to the Christian community (*ecclesia*) itself. Conversely, the Greek word *ecclesia* (*ἐκκλησία*) was transferred from the community to the building, and is used in both senses, especially in the modern Romance and Celtic languages (e.g., Fr. *église*, Welsh *eglwys*, etc.). The Gothic New Testament of Ulphilas has *aikklesjo*.

A. THE CHURCH: THE RELIGIOUS COMMUNITY

The English word "church" represents the Greek *ἐκκλησία* (naturalized in Latin as *Ecclesia*) in its specifically Christian use. Other uses of the Greek word shed no light on this, and may prove misleading if brought into comparison. As so used, its earliest appearance that we can date is in the Epistles of St. Paul, where it is evidently a familiar term. In the earliest of them the apostle

writes, "ye have heard of my manner of life in time past in the Jews' religion, how that beyond measure I persecuted the Church of God, and make havock of it." This phrase, *the Church of God* (τὴν ἐκκλησίαν τοῦ Θεοῦ), has a history behind it, which will show exactly in what sense it was here used.

In the Old Testament are two Hebrew words 'edah, and kahal, which in the LXX. are indiscriminately rendered συναγωγή or ἐκκλησία. In the Pentateuch both alike signify the general assembly of the people of Israel during the Wanderings. The word ἐκκλησία, which is so far confined to Deuteronomy in this connection a natural Hellenism. Elsewhere they mean the people itself, especially in its relation to God, with little or no reference to assembling. Striking examples are Nehemiah xiii. 1 where the phrase is ἐκκλησία θεοῦ, and Ps. lxxiv. 2, τῆς συναγωγῆς σου. The word συναγωγή is the more frequent, and this alone survived in current use among Hellenistic Jews in the sense of a local congregation, the familiar *synagogue*. What has to be considered is the reason why the other word was revived in Christian use. The origin and the essential character of the Church are involved in this enquiry.

As historical sources there is nothing else, except in some sections of the Acts, so entirely contemporary as St. Paul's Epistles; but in the Gospels and in the rest of the Acts, though the language may be coloured by later thought or experience, valuable material can be found. It is clear that the gospel began as a proclamation of the Kingdom of God (or of Heaven) having close affinity both with older Messianic prophecy referring to the lineage of David, and with more recent apocalyptic dreams. The proclamation was renewed in both aspects by the Apostles on the basis of belief in the resurrection and ascension of Jesus as the Christ. They gathered at Jerusalem a considerable number of disciples, forming a close community which was entered by the rite of baptism. There is reason to think that it was organized as a synagogue, one of the many in Jerusalem. In Aramaic "synagogue" is *knishtha*. The Church is still so called by the Aramaic Christians of Palestine. Hence, perhaps, the word *synagogue* in James ii. 2. In the 4th century Epiphanius writes clumsily of the Ebionites, συναγωγὴν καλοῦσι τὴν ἑαυτῶν ἐκκλησίαν καὶ οὐχὶ ἐκκλησίαν (*Adv. Haeres.* i. ii. 18). We hear of it later (Acts xv.) as governed by James with a bench of Presbyters, the usual equipment of a synagogue. Some Pharisees and some priests joined, and the disciples regularly took part in the worship of the Temple; but the high priest and the Sanhedrim were hostile, making intermittent attempts to suppress the movement.

The episode of Stephen was a turning point. It is evident that this Hellenistic Jew was out of sympathy with the dominant religious sentiments of Jerusalem, probably shared by the Apostles and most of their disciples. He seems to have anticipated revolutionary changes, involving the suppression of the Mosaic ordinances and even of the Temple. His defence before the Sanhedrim was a rapid survey of Old Testament history. That history is a record of repeated relapses and ruin of God's chosen people, followed by the recovery of a small remnant, the common subject of prophecy. Stephen is just approaching a prophetic warning when he is silenced. It is probable that this worked in the mind of St. Paul, as preparation for his conversion. It became a prominent element in his teaching that the prophetic doctrine of the Remnant was being fulfilled. The Jewish people as a whole had fallen away by their rejection of Jesus as Messiah; those who accepted him were the faithful remnant which was to be the beginning of a reconstitution of God's people. He develops the argument in Romans ix., xi., but the conclusion is condensed into one remarkable sentence, Philip iii. 3, "We are the circumcision, who worship by the spirit of God, and glory in Christ Jesus, and have no confidence in the flesh." In current speech "the circumcision" meant the Jewish people regarded as bound in covenant to God. The actual rite of circumcision was being abandoned by Christians, and the sentence may be paraphrased: "Not those who practise the circumcision of the flesh, but the believers in Jesus as the Christ, are all that circumcision signifies, the covenanted People of God." It is the proper conclusion of Stephen's interrupted argument. St. Paul himself, having heard the argu-

ment and taken an active part in the persecution that followed, was soon afterwards convinced of its truth. So he said that he had persecuted "the *ecclesia* of God."

Why that Greek word? It occurs in Stephen's defence, but we do not know that he spoke in Greek. It would be familiar to any diligent reader of the LXX. and peculiarly appropriate, as it appears in Nehemiah xiii. 1, where ἐκκλησία Θεοῦ means the returning exiles, the Remnant on which the people of God was to be reconstructed. Its use appears to be a deliberate archaism; the exact equivalent συναγωγή being current, but unsuitable because of its immediate associations. In the Aramaic of the Christians of northern Syria 'edta, a variant of the Hebrew 'edah, is a precisely similar archaism. A common place of origin is, perhaps, to be found at Antioch. Hort's hesitating suggestion that it may have been derived from the saying of our Lord recorded in Matt. xvi. 18 is unacceptable in view of the improbability that Greek was the language used on that occasion. If not, the use of ἐκκλησία there will be due to later coloration.

The use of the word thus indicates the definite application of the prophetic teaching about the Remnant to the new Christian community. This application was not peculiar to St. Paul; it is found also in the words quoted by James in Acts xv. 16, "I will build again the tabernacle of David which is fallen, and I will build again the ruins thereof." The rest of his quotation marks a second crisis: "That the residue of men may seek the Lord, and all the Gentiles, upon whom my name is called." It was not long after the episode of Stephen that St. Peter startled the community at Jerusalem by baptizing Cornelius the centurion at Caesarea, an example which appears to have been soon followed at Antioch. The Jewish Commonwealth had always been open to proselytes who received circumcision and undertook to observe the Mosaic law, but these new entrants did not conform to either condition. When the community at Jerusalem consented, perhaps reluctantly, to the innovation, a complete break with Judaism was bound to come. St. Paul was inclined to press it, arguing (rather inconsistently with the doctrine of the Remnant) that Jews and Gentiles had to enter equally into the new covenant (*Gal.* iii.), but he afterwards spoke of the Gentiles as engrafted into the stock of Israel (*Rom.* xi. 17).

The Church now became a Diaspora, like that of Judaism, extended in all directions by the work of the Apostles and their helpers, but retaining its headquarters at Jerusalem. Consequently, the word *ecclesia* speedily went the same way that the word *synagogue* had gone; from being the designation of the whole People of God, it became the designation also of local groups. This development was already complete when St. Paul addressed his first extant epistle to "the Churches of Galatia." Of the organization of these Churches we know very little, for our only informants had no occasion to describe what was familiar to those for whom they were writing. Two opinions on the subject stand in sharp contrast. The one is linked with Luther's conception of an "invisible" Church, the members of which are known only to God. Rudolph Sohm is the ablest recent exponent of this idea. According to him, believers in Jesus as Christ were at first united only by a spiritual nexus; but before long there was an inevitable attempt to bind together all putative believers in an external organization, which eventually claimed to be the true Church of God, thus corrupting the pure spirituality of the Gospel. The other opinion postulates a completely organized society, existing from the beginning and continuing, not indeed without changes, but in consistent development through subsequent ages. In reply to Sohm, Harnack stated this with much exaggeration, asserting that the Church began with an "abundant and elaborate equipment," and even with a "legal code" of complicated structure.

The truth seems to lie in a synthesis of the ideal and the actual contained in these extremes. Lightfoot constructed such a synthesis in his essay on *The Christian Ministry*. What discipleship meant was a spiritual union with the risen Christ, but this union was held to be mediated by the rite of baptism. According to St. Paul, to be baptized was to "put on Christ," (*Gal.* iii. 27). Those who thus "live by the Spirit" must also "walk by the Spirit"

(Gal. v. 25). But this spiritual walking was strictly controlled by the Apostles, who ruled the several Churches in a most peremptory manner, "So ordain I in all the Churches" (I. Cor. vii. 17) says St. Paul about the conduct of marriage. Their control secured some measure of uniformity; "We have no such custom, neither the Churches of God" (I. Cor. xi. 16) was sufficient reason for repressing an innovation. To keep things in order they visited the Churches, personally or by delegates, and in case of need wrote directive letters. In a striking metaphor they are to the Church as the foundation to a house (Eph. ii. 20), and this cannot refer only to the original preaching of the Twelve, for St. Paul certainly included Barnabas and himself. Thus the Apostolate extended as the Church extended, and was in the way of becoming a permanent institution. Of the interior order of the local Churches we know at least the existence of Presbyters, some of whom were called *ἐπίσκοποι* or overseers. Details must be treated elsewhere. The Church of the first age, therefore, certainly had an official equipment and some rules of conduct, but probably nothing so elaborate as Harnack supposed. Nor was this equipment alien to the spiritual character of the Church, for every function depended on a special gift of the Spirit, however mediated (I. Cor. xii.; Eph. iv.). (See MINISTRY, THE CHRISTIAN; EUCHARIST.)

For 30 years after St. Paul's latest epistle we are left without information. The *First Epistle of Clement* supplies nothing new, but 20 years later the *Epistles of Ignatius* show a development. The five Churches in Asia which he addresses are equipped with a hierarchy of deacons and presbyters under a chief who bears the old title of *ἐπίσκοπος* (bishop) but no longer as a subordinate; he appears to execute in that one Church all the functions of an apostle. It is a disputed question whether his office has grown out of the presbyterate or is a continuation of the apostolate. If he were invariably attached to a single city, the former theory would be strengthened; but it is not so, for Ignatius calls himself "bishop of Syria," and some years later a single bishop is found serving the whole of Gaul north of the Narbonensian province, a truly apostolic charge. The system of city-bishops became general within the Roman empire, but in northern Europe and elsewhere the system of regional bishops has always prevailed from the earliest times.

In Ignatius we find the important word "Catholic" describing the whole Church as distinct from local Churches. It is evidently a current term. He relates the bishop to a local Church as Jesus Christ to the Catholic Church (*Smyrn.* viii. 2). But in the *Martyrium Polycarpi*, some years later, the Church of Smyrna is called Catholic, perhaps as locally representing the whole. The word afterwards takes on a much larger content, indicating adhesion to the Christian religion as a whole, in contrast with the particularities of heresy, and so can be applied even to individual persons.

The First Reasoned Theory.—The 3rd century presents to us for the first time in its history a reasoned theory of the Church in the writings of St. Cyprian. He bases it on the episcopate, which he entirely identifies with the apostolate. Bishops are appointed by Christ himself, as the Apostles were, though the divine appointment is mediated by consecration, and even by some elements of popular election. The episcopate is one, and he illustrates its unity by terms borrowed from the Roman law of corporations. Nevertheless in each single place there is a single bishop who represents the whole, and of that place those inhabitants who communicate with the bishop, and none else, are in the communion of the Catholic Church. He has been generally followed, except in two particulars. He maintained: (1) that all bishops are precisely equal in authority, and (2) that a bishop is responsible only to God, and can be removed from his place, as he was appointed, only by God. The latter contention was confronted, in his own practice, by the obvious difficulty of ascertaining when the Divine judgment has fallen. A solution was soon found in the obvious inferiority of a single bishop to a council of bishops, which could therefore depose him. The case of Paul of Samosata settled this. Irenaeus had already noted the special weight of authority (*potentior principalitas*) exerted by

the bishop of Rome, and this was equally true of the other great capital cities, Alexandria and Antioch; Constantinople was afterwards added next to Rome, and the honorary addition of the restored Jerusalem completed the system of the patriarchates which dominated the Church in the eastern half of the Roman empire from Italy to the Euphrates. In the same part of the empire there was a similar aggrandisement of the bishop seated in the metropolis of each province, who presided over a manageable council of comprovincial bishops, and acquired a commanding influence in their appointment; a system which with some differences, was gradually extended westward, and into the countries beyond the empire.

Such is the working system of the Catholic Church, evolved from elements which we can discern in the first age. From the 5th century onward it has been complicated by claims made for the Church of Rome based on the promise of the Keys to St. Peter in Matt. xvi. 19. This requires separate treatment. It has been complicated also by obstinate schisms. Donatism in Africa was a passing trouble. Such also was the Arianism of the Goths, which for three centuries delayed the settlement of the Church in the new nations carved out of the Western empire. More permanent has been the separation, much more racial than theological, of Nestorians and Monophysites in the East from the orthodoxy of Constantinople. A succession of temporary quarrels between Constantinople and Rome led to the great breach of 1054 still continuing. (See PAPACY.)

In the 16th century the Reformation shattered the unity of the Western Church, contrary to the intention of the promoters, who aimed at reforming the whole Church "in head and members." The predestinarianism alike of Luther and of Calvin brought in the theory of the Invisible Church mentioned above, reducing the hierarchy to the level of a not indispensable expedient. Luther, regarding the Visible Church in this light, gave the chief control of it to the civil magistracy, in which he was followed or preceded by the Swiss Reformers and by those of the middle Rhine. Calvin established at Geneva a system of Presbytery, modelled on indications drawn from the Pauline Epistles and the Acts, acting in close connection with the magistracy and this was carried by his disciple, Theodore Beza, to the Reformed of France, in complete independence of a hostile State. The Genevan model was extended to the Netherlands, and the independent Presbytery of Beza was planted in Scotland by John Knox, to be afterwards perfected by Andrew Melville. This Presbyterianism followed with some exaggeration the lines of the Cyprianic episcopacy, while dropping the title of *bishop*, with all the associations which had gathered round it. In the Scandinavian countries the historic episcopate was retained by the reformers, and in England the organized administration connected with it also remained almost intact. The doctrinal aspects of the Reformation do not concern us here. (See REFORMATION.)

English Puritanism began as a demand for further reformation on the Swiss model, and with Thomas Cartwright took the form of an assertion of the Divine right of Presbyterianism, but a native development became much more important. Robert Browne, and after him Henry Barrow, deduced from the doctrine of the Invisible Church their conception of the "gathered Church," a group of believers voluntarily associated in complete independence, which they declared to be the only true Visible Church of the New Testament. This *Independency*, dominant during the crisis of the Civil War, survived its political failures, and remains, with various modifications, one of the chief factors in the Protestantism of English-speaking countries, where a "Church" is usually taken to be such an association, whether in its original form of a single congregation or in a close-knit and extensive system like those of the various Methodist connections. These developments will be found severally treated elsewhere. In their mutual antagonisms the idea of the Christian Church as a whole has been almost lost sight of, but it has recently revived in more friendly discussion, and is found to be firmly rooted in history.

B. THE CHURCH BUILDING

It is generally held that the Church, when established as part of the organization of the Roman Empire, adopted for its buildings the plan of the secular basilica, and the name basilican has been given to the plan consisting of a long hall or nave with aisles, and with a projecting semicircular apse at the end opposite the main entrance. It should be remembered that the secular basilica followed no stereotyped form of plan, and that other influences may have combined to determine the plan assumed by the Christian church fabric. Further, although the term basilica was very commonly applied to early Christian churches, it was by no means confined to aisled buildings, but was also used of simpler structures. The internal arrangement of the apse, however, closely resembled that of the apse of the basilican law-court. The altar, on the chord of the apse, took the place of the altar on which oaths were taken by deponents: the seats of the bishop and clergy, ranged behind it, corresponded to those of the secular magistrates. The *cancelli* or screen, which divided the tribunal from the body of the court, became the barrier between the congregation and the sacred rites, and gave its name to the chancel of the church.

Circular Plan.—An alternative plan to that of the long aisled nave was the circular or polygonal plan, radiating from a central point, of which the most famous example is the church of San Vitale at Ravenna. This had its origin in the plan of the Christian baptistery, which was symbolically derived from the centralized plans of funeral monuments. The centralized church-plan, however, was provided with an encircling aisle or ambulatory, above which was a tribune or gallery, and with a chancel for the altar. Thus the fundamental characteristic of the Christian church-plan is its division into the nave for the worshippers and the chancel for the altar and clergy. Covering the main entrance to the nave there was frequently a narthex or vestibule, originally used by catechumens or by penitents excluded from participation in the holy mysteries. In the earliest churches the chancel was at the west end of the building, and the celebrant at the altar faced the congregation, but eventually the custom of placing the chancel at the east end of the church, which first appears in the basilicas of Ravenna prevailed, the celebrant still facing eastward. Beneath the altar there was often a crypt, the *martyrium* or *confessio*, so called from its traditional identity with the place of death or burial of the saint to whom the church was dedicated. The choir of singers was accommodated on the altar platform on either side of which were the *ambones* or pulpits from which the epistle and gospel were read.

In the larger Romanesque churches of western Europe, the aisled nave was practically universal, and the problem of covering these long structures with vaults of stone produced the characteristic art of the middle ages. Towers rose at the west ends of the aisles, and the erection of a tower on piers and arches between nave and chancel led to the development of the transept or cross-arm for purposes of abutment. It was, however, at the east end of the church that the principal development of plan took place. An aisled presbytery was interposed between the apse and the nave, and the aisles were in many instances continued round the apse, forming an ambulatory with a ring of chapels opening eastward from it. This arrangement, dictated by the requirements of processions and by the need of additional altars, became the regular plan of the French Gothic church, producing those magnificent *chevets* of apse and chapels which are the greatest masterpieces of mediaeval art. The process of enlargement and rebuilding, which attained its height in the thirteenth century, was due to the necessity of a larger ritual space and to the multiplication of endowments for masses. The east arms of churches were reconstructed on a large scale. Behind the altar in many churches rose the shrine of the local saint, the object of pilgrimages which enriched the church and its

fabric. A Lady chapel, where the mass of the Blessed Virgin was celebrated daily, was often the most prominent of the chapels at the east end of the church, though its position on the plan varied. The transepts had their eastern aisles of chapels, and the spaces between the buttresses of the nave were utilised for the same purpose.

The Small Parish Church, usually an aisleless structure with nave and chancel, and with western or central tower, also underwent enlargement as local needs demanded. The nave was aisled; the chancel was lengthened; chapels were added at various points in the plan, which sometimes became extremely complex. Such enlargements and additions did not imply growth of population and the consequent need of a larger area for worshippers. Their cause was local anxiety to contribute to the pious work of church-building, and, where the means of benefactors allowed, to provide altars at which masses, maintained by their endowments, could be celebrated for the health of their souls. In certain districts church-building was encouraged by agricultural or commercial prosperity, by the existence of guilds which vied with one another in founding chantries, and by abundance of good local material and ease or cheapness of carriage. The architectural history of parish churches was much affected by the division of responsibility for cost between the rector, who met the repairs of the chancel, and the parishioners, who maintained the rest of the building by their contributions to the fabric fund or "works," under the administration of the church wardens, the *custodes fabricae* or *operis*.

It is often stated that the church architecture of the middle ages was dictated by an elaborate scheme of religious symbolism. While symbolical ideas entered into the adoption of certain types of plan, as in the transference, already mentioned, of the mausoleum plan to the baptistery, experience shows that the lay masons who usually carried out the work of building were guided by practical considerations, structural and ritual, whose free and natural expression would have been fettered by adherence to artificial rules of symbolism. Anomalies or deviations from regularity of plan, for which deep significances have been sought, can generally be assigned to errors of setting-out or to imperfect workmanship. The beauty and nobility of mediaeval church architecture is the result of the perfectly natural and unaffected response of the builders to the necessities of construction and to the immediate demands of the religious cult for which they laboured.

Artistic Development.—In some later mediaeval churches, especially those of friars, wide naves were provided for preaching purposes. Usually the interior of the church was broken up by the screens which enclosed the chapels in the aisles and beneath the arches. Between the nave and chancel was the screen, the western counterpart, with open tracery in its panels, of the closed iconostasis of the Eastern Church: above it was the loft or gallery and the beam on which stood the crucifix. In cathedral and collegiate churches the screen was habitually a solid erection of stone, shutting off the choir services from the nave; while in monastic churches, including several of the English cathedrals, there were two transverse screens, the choir-screen with its *pulpitum* or loft to the east, and the rood-screen a bay or two west of it. As the middle ages advanced, with the growth of specialization in various departments of church fittings, the church became more and more the frame and setting for works of art in stone, marble, alabaster, wood and stained glass. From the beginning colour played a large part in internal effect, as in the mosaic incrustation of early Christian churches. Rough walls were plastered and pictures or patterns painted on the dry surface or in fresco. The window-openings were filled with stained glass; pigments were lavishly employed on ceilings, on the surface of piers and vaults, and on furniture. In such prodigality of colour the mediaeval mind found the fullest satisfaction of its religious ideals. By the contemplation of the works of art that filled his church, Suger, the great abbot of Saint-Denis, tells us that he felt himself lifted in spirit from the world to a purer clime; and in Italy and Flanders the art of painting grew to perfection in the decoration of church walls and altars.

The Renaissance.—In countries which embraced the Reformation, the work of church-building was checked. The prime motive which up to that time had prompted the rebuilding or extension of so many churches was gone and existing buildings fully met the requirements of reformed worship. But in any case the Gothic art of the middle ages was already disappearing before the revival of classic art which had its birth in Italy. The ruthlessness which mediaeval artists had shown to the work of their predecessors was pursued by the architects of the Renaissance, who thought nothing of sweeping away great historic monuments like St. Peter's at Rome to make way for buildings in their new style. At the same time, while this implied a change in methods of construction and decoration, those methods were adapted to the traditional Christian church plan, and the combination of classical architecture with mediaeval traditions of planning and design is nowhere more clearly seen than in St. Paul's Cathedral and in other churches designed by Wren and the English architects who followed in his footsteps. While the church plan, during the period of Renaissance influence, underwent some simplification, and the idea of the large auditorium or hall of worship superseded the practice of the middle ages and survived in the churches of the Gothic revival, it still retained the fundamental character of the plan which had approved itself as suitable for the needs of the early Church and had reached its highest development in conformity with the requirements of mediaeval ritual. (A. H. T.)

See RELIGIOUS AND MEMORIAL ARCHITECTURE.

CHURCH AND STATE. The relation of Church and State in England, conveniently summed up in the word "establishment," is curiously complicated, including elements of great antiquity and arrangements made as recently as the year 1919. The antiquary, the historian, the lawyer, and the ecclesiastical find ample materials for their several studies in the Church of England as by law established. With the partial exception of Sweden, England was the only country in which the Reformation did not involve an almost complete breach with the system of the mediaeval Church. The main lines of the existing ecclesiastical system are mediaeval—the hierarchy, the parochial system, the convocations, the presence of the archbishops and bishops in the House of Lords, the canon law in so far as it was perpetuated by the legislation of Henry VIII., and the ecclesiastical courts. The Reformation effected a threefold change—social, doctrinal and constitutional. By the abolition of the monasteries, and the confiscation of the monastic property, the spiritual estate was weakened and impoverished: by the changes in doctrine and discipline the Church of England abandoned the distinctive beliefs and devotions of mediaeval Christianity; and by the acceptance of the royal supremacy, it not only repudiated the authority of the Roman pope, but received the status and constitution of an independent national Church. Since the 16th century the acceptance of the policy of religious toleration by the State, and the evolution of democracy, have affected importantly the system of the Established Church. The growth of nonconformity, the expansion of the insular kingdom into the British empire, the secularisation of parliament, and the development of denominational self-assertion within the Church itself have all affected the existing relations of Church and State in England. Establishment in its present form may be conveniently considered under five heads, viz., the royal supremacy, the authority of parliament, the ecclesiastical courts, patronage, the tenure of the ancient endowments.

The Royal Supremacy.—Henry VIII. forced the convocations to recognize his "headship" of the Church of England, but mitigated the unquestionable innovation by the pretence that he was but vindicating and restoring to the Crown the authority in ecclesiastical matters which was inherent in the monarchy by divine right, and had been recognized in practice until the usurpation of the Roman popes had obscured and superseded it. The revolutionary statutes which abolished the papal authority, and severed the national Church from the larger ecclesiastical system of which it had hitherto formed part, adopted a demurely constitutional tone, emphasizing the ancient independence

and imperial self-sufficiency of the realm under its monarch. Thus the Restraint of Appeals, A.D. 1533, begins:

Where by divers sundry old authentic histories and chronicles it is manifestly declared and expressed, that this realm of England is an empire, and so hath been accepted in the world, governed by one supreme head and king, having the dignity and royal estate of the imperial crown of the same, unto whom a body politic, compact of all sorts and degrees of people, divided in terms, and by names of spirituality and temporality, be bounden and ought to bear, next to God, a natural and humble obedience, etc.

That the royal authority over the Church in England had been very great in the past, and that the power of the popes had grown to exorbitant proportions in the period immediately preceding the Reformation, were unquestionable facts, and they gave plausibility to a contention which was, none the less, essentially untrue. The supremacy which the royal headship implied was a new thing in Christendom, and had no real precedents in history. It owed its origin to the novel conditions of the age, and its form to the masterful despot who arrogated it to himself. The functions withdrawn from the pope were accumulated on the monarch. Henry VIII., uniting in his own hands the plenitude of power both civil and spiritual, became in Bishop Stubbs's notable phrase, "the pope, the whole pope, and something more than the pope." (*Lectures on Mediaeval and Modern History*, p. 301.) So monstrous a claim could not be maintained. Under Elizabeth the royal supremacy was defined and delimited, and the much debated title, "head of the Church," was laid aside. Article XXXVII., which still binds the English clergy, claims for the sovereign "that only prerogative, which we see to have been given always to all godly Princes in holy Scriptures by God himself; that is, that they should rule all estates and degrees committed to their charge by God, whether they be Ecclesiastical or Temporal, and restrain with the civil sword the stubborn and evildoers." The Article adds that "the Bishop of Rome hath no jurisdiction in this Realm of England." So long as the royal supremacy was exercised by a sovereign who was himself a Christian man this definition served well enough: but the development of the English constitution from the practical autocracy of the Tudor sovereigns to the limited monarchy of their latest successors, has had its effect on the ecclesiastical system, and raised some formidable questions, of which the answer is not yet apparent.

Parliament.—The legislative authority of the mediaeval Church had been "spiritual." In the last resort the Church in England was governed by the canons of general councils and by the decretals of the popes. These controlled the action of the provincial convocations, which held the status of subordinate legislatures. The abolition of extra-national authorities, papal and conciliar, left nothing but the convocations of Canterbury and York in existence. In these circumstances the king and parliament may be said to have taken over the legislative functions of the pope and the general council. The Church of England before the Restoration was governed by ordinances and statutes. Church and nation were identified, at first practically, and then theoretically. The identification was defended with impressive eloquence by Hooker (d. 1600) and became the assumption of the English establishment. The convocations continued to legislate under the severe limitations imposed by 25 Henry VIII. cap. 19. (The Submission of the Clergy and Restraint of Appeals, 1534), and the mediaeval canon law retained under the same act a carefully restricted authority, but the right of parliament to legislate for the national Church even in "spiritual" matters was asserted and acted upon. The right was grounded on the Christian character of parliament, and on its essential function. Only by recognizing the legislative supremacy of parliament could the unity of the church-nation be secured. The 17th century witnessed the triumph of constitutional government, and the beginning of religious toleration. Legislative authority once shared between king and parliament became vested in parliament alone. The national Church was no longer governed partly by royal ordinance. James II.'s claim to the dispensing power was disallowed. While, however, the Act of Settlement (1701), provided that "whosoever shall hereafter come to the possession of this Crown shall join in communion with the Church of England, as by law established," it did not provide

against the danger implicit in a change in the religious character of parliament. The danger of Roman Catholic members was indeed guarded against by the Test Act (1673); but 45 Presbyterians were admitted by the Act of Union with Scotland, A.D. 1707, and in the course of the 19th century parliament was opened to Nonconformists, Roman Catholics, Jews, and non-believers of every description. Parliament, thus frankly divorced from an ecclesiastical character, retained its ecclesiastical functions unaltered. The anomaly was apparent and increasingly resented as the Church of England, waking from the deep slumbers of the 18th century, felt and acted as a spiritual society. The influence of the Oxford Movement tended powerfully in the same direction. In 1852 the convocations, which had been suspended for 135 years, again were permitted to function. Parliament ceased to be the sole organ of ecclesiastical legislation and henceforth found its action conditioned by the constitutional rights of a clerical legislature, subordinate indeed, but as ancient as itself, and within its own sphere as independent. Nor was this all. While parliament became patently unqualified for ecclesiastical legislation, its secular task, ever waxing with the expansion of the empire, and the complexity of social life, required its undivided concern. Urgent ecclesiastical reforms were postponed for no better reason than the congestion of parliamentary business. Accordingly the demand for better legislative machinery became general, and, in the general reconstruction of the national system which followed the World War, was met by the Enabling Act (1919). A new body, the National Assembly, was created consisting of three "houses"—the diocesan bishops, the members of both convocations and elected laity. To this body legislative authority, subject to the veto of either house of parliament, was given. Measures affecting the Church of England passed by the National Assembly, certified as constitutional by an ecclesiastical committee created for the purpose, and approved by both houses of parliament, were to have the force of statutes on receiving the royal assent. The constitution of the National Assembly both reserved unaltered "the powers belonging to the convocations of the provinces of Canterbury and York or of any House thereof," and prohibited the Assembly from "exercising any power or performing any function distinctively belonging to the bishops in right of their episcopal office." This devolution of legislative power by parliament to the Assembly did not destroy the right of parliament to make laws for the Church of England, but rendered the exercise of that right abnormal and improbable. The right of a spiritual society to be truly autonomous in spiritual matters is obviously patient of large secular control in other directions: but the line between spiritual and secular is not always easy to trace, and the intermingling of secular and ecclesiastical interests in an anciently Christian community is extremely close. The Enabling Act, however, carries the possibility of future trouble. In twice rejecting the Prayer Book Measure (1927 and 1928) the House of Commons has precipitated a conflict on a plainly spiritual issue, which must affect gravely the Establishment itself, and may even bring about its destruction.

The Ecclesiastical Courts.—The unique character of the English Reformation as at once conservative and revolutionary is nowhere better exhibited than in the ecclesiastical courts. They are the provincial and diocesan courts of the mediaeval Church, but they are held in the king's name, the law they administer is the king's ecclesiastical law, and they are subject to the appellent authority of the king's privy council. The modern system has departed in some important respects from that which the Reformation created. It is much more nakedly secular, for the study of canon law having practically ceased, and the race of canonists having died out, there was left no effective check on the secularising tendency of the lawyers, who of old time cherished a professional dislike of the ecclesiastical jurisdiction, and sought after a simplification of the legal system which paid little heed to tradition and the claims of the "spirituality." In the course of time, notably during the 19th century the limits of ecclesiastical jurisdiction have been greatly contracted by the withdrawal of suits relating to wills, marriage, and tithes. Acts of parliament are administered in the ecclesiastical courts, not any more the mediae-

val canon law, save where this has acquired statutory force from the provisional legislation of Henry VIII. The ecclesiastical judges are laymen, and they acknowledge the supreme appellent authority of the judicial committee of the privy council. This progressive secularisation of the Church's legal system did not provoke resentment until, largely as a consequence of the Oxford Movement, the ecclesiastical courts had to deal with suits affecting the interpretation of rubrics and doctrinal standards. That such subjects, affecting the worship and belief of churchmen, should be handled by secular lawyers, who might not even themselves be Christians, offended the new sense of ecclesiastical independence, and did violence to the religious conscience of many devout persons. The courts were denounced as "Erastian," and a disposition manifested itself to repudiate their authority. This disposition has certainly been strengthened by the course of national politics. A breach has opened between the general sentiment of English churchmen and the settled policy of the State in the matters of religious education and the marriage law, which is not likely to be closed, and which tends to create an attitude of apprehension and suspicion not favourable to the easy working of the establishment. A commission charged to make recommendations for the reform of the ecclesiastical courts was appointed by the National Assembly, and has issued its report. It is understood (1928) that legislation will be shortly attempted. Meanwhile the general discontent with the existing courts, and the widely extended disposition to ignore their verdicts, add an element of special embarrassment to the problem of maintaining discipline in the Church.

Patronage.—No part of the establishment is more distinctive, and none more perplexing than "patronage," that is, the process by which clergymen are appointed to office. It presents a curious blending of ancient and modern elements. The higher ecclesiastics—bishops, deans, some canons and many incumbents—are appointed by the crown on the nomination of the prime minister. In the case of the ancient sees, the mediaeval process is still followed, viz., *congé d'élire* to the dean and chapter accompanied by letters missive containing the name of the person whom they are desired to elect, confirmation by the archbishop, consecration, homage, and enthronement in the cathedral. In the case of modern sees which have no cathedral chapters, the bishop is appointed by letters patent. Two archbishops and 24 bishops sit in parliament—the archbishops and the bishops of London, Durham and Winchester by right of their sees, the other bishops by seniority of their consecration. The incumbents are nominated to the bishop of the diocese by patrons, who are either public (the lord chancellor, the bishops, colleges, the deans and chapters and other ecclesiastics holding patronage by title of their benefices), or private. The bishop has a limited power of refusing institution, but, in the absence of disqualification duly proved, he must institute and induct the patron's nominee to the benefice. This system is criticised as providing no adequate protection of parishioners against unsuitable appointments, and various projects for amending it have been advanced: but it is generally allowed that patronage, although anomalous in theory does not work badly, and there is no agreement as to a satisfactory substitute. The system is closely bound up with the method by which the parochial clergy are remunerated. The parish is also a benefice, and the incumbent possesses a life-tenure of the endowment attached to it. This also is much objected against by reformers, but it does not lack apologists. Opinion, however, seems to be tending towards an age-limit, which would remedy the principal fault of the existing system, viz., the incompetence of aged and ailing clergymen. A recent measure securing a modest pension at the age of 70 has laid the foundation for further reforms.

Tenure of the Ancient Endowments.—The Church of England is an endowed Church, and, if it were disestablished, its claim to retain possession of the ancient endowments would certainly be disallowed. These endowments—fabrics, tithes, glebes, investments—are held by a multitude of corporations, sole and aggregate, on a service tenure, which is stated in the statutes which prescribe the functions of the bishops and clergy. Disestablishment would involve the dissolution of all these corporations. Such property as might be left to the disestablished Church would

be held under conditions which the Act of Disestablishment and Disendowment would create. It is the tenure of the endowments which forms now the most important aspect of the English establishment, and the prospect of their partial or total loss constitutes the weightiest of all arguments against disestablishment. Statesmen shrink from the grievous social and economic disturbance which disendowment could not but involve. Churchmen dread the loss of the material resources which maintain throughout the country the ministrations of religion. Neither the reluctance of the first nor the apprehensions of the last could avert the catastrophe if a breach between Church and State on a point of religious principle were to take place, and prove incapable of remedy.

SCOTLAND

If the establishment in England is the most complicated, that in Scotland is the simplest which Christendom includes. In Scotland a "clean sweep" of the mediaeval system was effected. The Church was equipped with a new polity, and in the course of history acquired an unprecedented independence. Its constitution as set out in the Church of Scotland Act, 1921, exhibits the model of "a free Church in a free State," such as Cavour projected in the middle of the 19th century. The 3rd Article "declaratory of the Constitution of the Church of Scotland in Matters Spiritual" runs thus:

This Church, as part of the Universal Church wherein the Lord Jesus Christ has appointed a government in the hands of Church office-bearers, receives from Him, its Divine King and Head, and from Him alone, the right and power subject to no civil authority to legislate and to adjudicate finally, in all matters of doctrine, worship, government, and discipline in the Church, including the right to determine all questions concerning membership and office in the Church, the constitution and membership of its Courts, and the mode of election of its office-bearers and to define the boundaries of the spheres of labour of its ministers and other office-bearers. Recognition by civil authority of the separate and independent government and jurisdiction of this Church in matters spiritual, in whatever manner such recognition be expressed, does not in any way affect the character of this government and jurisdiction as derived from the Divine Head of the Church alone, or give to the civil authority any right of interference with the proceedings or judgments of the Church within the sphere of its spiritual government and jurisdiction.

Partly, this unique independence may be ascribed to the presbyterian polity which, while magnifying the ministry, gave comparatively little importance to any section of it. There was nothing in Scotland parallel in political function to the episcopate in England. Partly, the emphasizing of ecclesiastical independence has grown from the union of the kingdoms, at first personal and then, since 1707, parliamentary also. When the centre of national government had been removed to London, and Scottish business became a comparatively subordinate element in British politics, the Church of Scotland ceased to move the anxious concern of statesmen, while it acquired in the popular regard an ever greater importance as the principal, almost the only surviving, witness of an independent Scottish nationality. In more recent times, in Scotland as elsewhere, the secularisation of society has deprived all ecclesiastical concerns of much of their former importance. The attendance of the king's commissioner at the annual meeting of the general assembly, and the appointment of a number of presbyterian ministers as royal chaplains, form the chief tokens of that connection with the State which is the core of establishment. The State exercises no control over legislation, or ecclesiastical courts, or patronage. Establishment in Scotland has no practical importance, though unquestionably its sentimental value as a solemn recognition of national Christianity is still great, and its abolition would be regretted by many, probably by most, Scottish citizens.

THE UNITED STATES AND THE BRITISH DOMINIONS

Save in Great Britain, there is no established Church throughout the English-speaking communities, though the relations of the Churches to the State are everywhere friendly. Bryce's description of the situation in the United States holds good throughout the British Dominions:

The legal position of a Christian church is in the United States simply that of a voluntary association, or group of associations,

corporate or unincorporate, under the ordinary law. There is no such thing as a special ecclesiastical law; all questions, not only of property but of church discipline and jurisdiction, are, if brought before the courts of the land, dealt with as questions of contract; and the court, where it is obliged to examine a question of theology, as for instance whether a clergyman has advanced opinions inconsistent with any creed or formula to which he has bound himself—for it will prefer, if possible, to leave such matters to the proper ecclesiastical authority—will treat the point as one of pure legal interpretation, neither assuming to itself theological knowledge, nor suffering considerations of policy to intervene.

Religious bodies are in so far the objects of special favour that their property is in most States exempt from taxation; and this is reconciled to theory by the argument that they are serviceable as moral agencies, and diminish the expense incurred in respect of police administration.

It would perhaps be true to say that there is an informal establishment of Christianity though not of the Churches. It is assumed that society is Christian. Religious acts inaugurate the sessions of the representative assemblies, and no public function would be considered complete without them. Undoubtedly this informal establishment by public opinion and social habit is menaced by the increasing secularisation of society, but it is still strongly entrenched in the public sentiment of all English-speaking communities. Establishment in the true sense is limited to England and Scotland, and only in England does it possess any importance, or present any legal and constitutional problems.

(H. H. H.)

CHURCH ARMY, an English religious organization, founded in 1882 by the Rev. Wilson Carlile (afterwards prebendary of St. Paul's), who banded together in an orderly army of "soldiers" and "officers" a few working men and women, whom he and others trained to act as "Church of England evangelists" among the outcasts and criminals of the Westminster shums. Previous experience had convinced him that the moral condition of the lowest classes of the people called for new and aggressive action on the part of the Church, and that this work was most effectively done by laymen and women of the same class as those whom it was desired to touch. It is essentially a working men's and women's mission to working people. As the work grew, a training institution for evangelists was started in Oxford, but soon moved (1886) to London, where, in Bryanston Street near the Marble Arch, the headquarters of the army are now established. Working men are trained as evangelists, and working women as mission sisters. Officers and sisters are paid a limited sum for their services either by the vicar or by voluntary local contributions. Church Army mission and colportage vans circulate throughout the country parishes, if desired, with itinerant evangelists, who hold simple missions, without charge, and distribute literature. Each van missionary has a clerical "adviser." Missions are also held in prisons and workhouses, at the invitation of the authorities. In 1888 (before the similar work of the Salvation Army was inaugurated) the Church Army established labour homes in London and elsewhere, with the object of giving a "fresh start in life" to the outcast and destitute. The Army has lodging homes, employment bureaux, cheap food depots, old clothes department, dispensary and a number of other social works. There is also an extensive emigration system, under which carefully tested men and families, of good character, chiefly of the unemployed class, are placed in permanent employment in Canada through the agency of the local clergy.

See Carlile, art. "Church Army" in Hasting's *Encyclopaedia of Religion and Ethics*, vol. iii.; Rowan, *Wilson Carlile and the Church Army*; *The Church Army Review*, and other publications of Headquarters.

CHURCH ASSEMBLY: see CANON LAW: *Church of England*, CONVOCATION, and ENGLAND, CHURCH OF.

CHURCH CONGRESS, originally an annual meeting of members of the Church of England, lay and clerical, to discuss matters religious, moral or social, in which the church is interested. It has no legislative authority, and there is no voting on the questions discussed. The first congress was held in 1861 in the

hall of King's College, Cambridge, and was the outcome of the revival of convocation in 1852. The term is now used to designate similar meetings of laymen and ministers of any religious denomination. *See ENGLAND, CHURCH OF.*

CHURCH COUNCIL: *see* COUNCIL and CHURCH HISTORY.

CHURCH HISTORY. In the following account of the historical evolution of the Church, the subject will be treated in three sections:—(A) The ancient Church to the beginning of the pontificate of Gregory the Great (A.D. 590); (B) The Church in the middle ages; (C) The modern Church.

A. THE ANCIENT CHURCH

The crucifixion of Jesus Christ resulted in the scattering of His followers, but within a short time they became convinced that He had risen from the dead, and would soon return to set up the expected Messianic kingdom, and so to accomplish the true work of the Messiah (*cf.* Acts i. 6 ff.). They were thus enabled to retain the belief in His Messiahship which His death had threatened to destroy permanently. This belief laid upon them the responsibility of bringing as many of their countrymen as possible to recognize Him as Messiah, and to prepare themselves by repentance and righteousness for the coming kingdom (*cf.* Acts ii. 21, 38, iii. 19 *et seq.*). In Jerusalem the new movement had its centre, and the church established there is rightly known as the mother church of Christendom. The life of the early Jewish disciples, so far as can be judged from our very meagre sources, was very much the same as that of their fellows. They continued faithful to the established synagogue and temple worship (*cf.* Acts iii. 1), and did not think of founding a new sect, or of separating from the household of Israel (*cf.* Acts x. 14, xv. 5, xxi. 21.) There is little evidence that their religious or ethical ideals differed in any marked degree from those of the more serious-minded among their countrymen, for the emphasis which they laid upon the need of righteousness was not at all uncommon. In their belief, however, in the Messiahship of Jesus, and their consequent assurance of the speedy establishment by Him of the Messianic kingdom, they stood alone. The first need of the hour, therefore, was to show that Jesus was the promised Messiah in spite of His crucifixion, a need that was met chiefly by testimony to the resurrection, which became the burden of the message of the early disciples to their fellow-countrymen (*cf.* Acts ii. 24 ff., iii. 15 ff., v. 31). It was this need which led also to the development of Messianic prophecy and the ultimate interpretation of the Jewish Bible as a Christian book (*see* BIBLE). The second need of the hour was to bring the nation to repentance and righteousness in order that the Kingdom might come (*cf.* Acts iii. 19).

Its Early Difficulties.—Meanwhile the new movement spread quite naturally beyond the confines of Palestine and found adherents among the Jews of the dispersion. Among the Christians who did most to spread the gospel in the Gentile world was the apostle Paul, whose conversion was the greatest event in the history of the early Church. In his hands Christianity became a new religion, fitted to meet the needs of all the world, and freed entirely of the local and national meaning which had hitherto attached to it. Paul saw in Jesus much more than the Jewish Messiah. He saw in Christ the divine Spirit, who had come down from heaven to transform the lives of men, all of whom are sinners. The Kingdom of which the early disciples were talking was interpreted by Paul as righteousness and peace and joy in the Holy Ghost (Rom. xiv. 17), a new principle of living, not a Jewish State. But Paul taught also, on the basis of a religious experience and of a distinct theory of redemption, that the Christian is freed from the obligation to observe the Jewish law. He thus did away with the fundamental distinction between Jews and Gentiles. The transformed spiritual life of the believer expresses itself not in the observance of Jewish law, but in love, purity and peace. This precipitated a very serious conflict, of which we learn something from the Epistle to the Galatians and the Book of Acts (xv. and xxii.).

It was Christianity in its universal form which won its great victories, and finally became permanently established in the Roman world. The appeal which it made to that world was many-sided.

It was a time when men were awaking to the need of better and purer living. To all who felt this need Christianity offered high moral ideals, and a tremendous moral enthusiasm, in its devotion to a beloved leader, in its emphasis upon the ethical possibilities of the meanest, and in its faith in a future life of blessedness for the righteous. It was a time of great religious interest, when old cults were being revived and new were finding acceptance on all sides. Christianity, with its one God, and its promise of redemption and a blessed immortality based upon divine revelation, met as no other contemporary faith did the awakening religious needs. It was a time also of great social unrest. With its principle of Christian brotherhood, its emphasis upon the equality of all believers in the sight of God, and its preaching of a new social order to be set up at the return of Christ, it appealed strongly to multitudes, particularly of the poorer classes. That it won a permanent success, and finally took possession of the Roman world, was due to its combination of appeals.

Christianity was essentially a proselytizing religion, not content to appeal simply to one class or race of people, and to be one among many faiths, but believing in the falsity or insufficiency of all others and eager to convert the whole world, but it did not win its victory without a struggle. Superstition, misunderstanding and hatred caused the Christians trouble for many generations, and governmental repression they had to suffer occasionally, as a result of popular disturbances. No systematic effort was made by the imperial authorities to put an end to the movement until the reign of Decius (250–251), whose policy of suppression was followed by Diocletian (303 ff.) and continued for some years after his abdication. In spite of all opposition the Church steadily grew, until in 311 the emperor Galerius upon his death-bed granted it toleration; and in 313 the emperors Constantine and Licinius published the edict of Milan, proclaiming the principle of complete religious liberty, and making Christianity a legal religion in the full sense.

Constantine, recognizing the growing strength of the Church and wishing to enlist the loyal support of the Christians, treated them with increasing favour, and finally was baptized upon his death-bed (337). Under his successors, except during the brief reign of Julian (361–363), when the effort was made to reinstate paganism in its former place of supremacy, the Church received growing support, until, under Theodosius the Great (379–395), orthodox Christianity, which stood upon the platform adopted at Nicaea in 325, was finally established as the sole official religion of the state, and heathen worship was put under the ban. The union between Church and State thus constituted continued unbroken in the East throughout the middle ages. The division of the Empire resulted finally in the division of the Church, which was practically complete by the end of the 6th century, but was made official and final only in 1054, and the Eastern and Western halves, the Greek Catholic and the Roman Catholic Churches, went each its separate way.

For long after the establishment of Christianity as the State religion, paganism continued strong, especially in the country districts, and in some parts of the world had more adherents than Christianity, but at length the latter became, at any rate nominally, the faith of the whole Roman world. Meanwhile already before the 3rd century it went beyond the confines of the Empire in Asia, and by the end of the period was strong in Armenia, Persia, Arabia and even farther east. It reached the barbarians on the northern and western borders at an early day, and the Goths were already Christians of the Arian type before the great migrations of the 4th century began. Other barbarians became Christian, some in their own homes beyond the confines of the Empire, some within the Empire itself, so that when the hegemony of the West passed from the Romans to the barbarians the Church lived on. Thenceforth for centuries it was not only the chief religious, but also the chief civilizing, force at work in the Occident.

The Christian Life.—The most notable thing about the life of the early Christians was their vivid sense of being a people of God, called and set apart. They regarded themselves as separate from the rest of the world and bound together by peculiar ties; their citizenship was in heaven, not on earth (*cf.* Phil. iii.

20, and the epistle to Diognetus, c. 5), and the principles and laws by which they strove to govern themselves were from above: the present world was but temporary, their true life was in the future; Christ was soon to return, and the employments and labours and pleasures of this age were of small concern. The belief that the Church was a supernatural institution found further expression in the conviction of the presence and power of the Holy Spirit, supposed to be manifest in various striking ways, in prophecy, speaking with tongues and miracle-working. In this idea Paul also shared, but he carried the matter farther than most of his contemporaries and saw in the Spirit the abiding power and ground of the Christian life. Not simply in extraordinary phenomena, but also in the everyday life of Christians, the Holy Spirit was present, and all the Christian graces were the fruits (cf. Gal. v. 22). A result of this belief was to give their lives a peculiarly enthusiastic or inspirational character. Theirs were not the everyday experiences of ordinary men, but of men lifted out of themselves and transported into a higher sphere. With the passing of time the early enthusiasm waned, the expectation of the immediate return of Christ was widely given up, the conviction of the Spirit's presence became less vivid, and the conflict with heresy in the 2nd century led to the substitution of official control for the original freedom (see below). The late 2nd century movement known as Montanism was in essence a revolt against this growing secularization of the Church, but the movement failed, and the development against which it protested was only hastened. The Church as an institution now looked forward to a long life upon earth and adjusted itself to the new situation, taking on largely the forms and customs of the world in which it lived. This did not mean that the Church ceased to regard itself as a supernatural institution, but only that its supernatural character was shown in a different way; the early conviction of the essential difference between the life of this world and that of the next lived on, and, as the Church became increasingly a world-institution, found vent in monasticism, which was simply the effort to put into more consistent practice the other-worldly life, and to make more thoroughgoing work of the saving of one's soul.

There were Christian monks as early as the 3rd century, and before the end of the 4th monasticism (*q.v.*) was an established institution both in East and West. The monks and nuns were looked upon as the most consistent Christians, and were honoured accordingly. Those who did not adopt the monastic life endeavoured on a lower plane and in a less perfect way to realize the common ideal, and by means of penance to atone for the deficiencies in their performance. The existence of monasticism made it possible at once to hold up a high moral standard before the world and to permit the ordinary Christian to be content with something lower. With the growth of clerical sacerdotalism the higher standard was demanded also of the clergy, and the principle came to be generally recognized that they should live the monastic life so far as was consistent with their active duties in the world. The chief manifestation of this was clerical celibacy, which had become widespread already in the 4th century. Among the laity, on the other hand, the ideal of holiness found realization in the observance of the ordinary principles of morality recognized by the world at large, in attendance upon the means of grace provided by the Church, in fasting at stated intervals, in eschewing various popular employments and amusements, and in almsgiving and prayer. Christ's principle of love was widely interpreted to mean chiefly love for the Christian brotherhood, and within that circle the virtues of hospitality, charity and helpfulness were widely exercised.

Worship.—The primitive belief in the immediate presence of the Spirit affected the religious services of the Church. They were regarded in early days as occasions for the free exercise of spiritual gifts. As a consequence the completest liberty was accorded to Christians to take such part as they chose, it being assumed that they did so only under the Spirit's prompting. But the result of this freedom was confusion and discord, as is indicated by Paul's 1st Epistle to the Corinthians (see ch. xi., xiv.). This led to the erection of safeguards. Particular Christians were designated to take charge of the services, and orders of worship were framed

out of which grew ultimately elaborate liturgies (see LITURGY). The Lord's Supper first took on a more stereotyped character, and prayers to be used in connection with it are found in the *Didachē* (ch. ix., x.). There developed in the 3rd or 4th century what is known as the *arcani disciplina*, or secret discipline of the Church, involving concealment from the uninitiated and unholy of the more sacred parts of the Christian cult, such as baptism and the eucharist, with their various accompaniments, including the Creed and the Lord's Prayer. The same interest led to the division of the services into two general parts, which became known ultimately as the *missa catechumenorum* and the *missa fidelium*,—that is, the more public service of prayer, praise and preaching open to all, including the catechumens or candidates for Church membership, and the private service for the administration of the eucharist, open only to full members of the Church in good and regular standing. Meanwhile, as the general service tended to grow more elaborate, the *missa fidelium* tended to take on the character of the current Greek mysteries (see EUCHARIST). Many of the terms in common use in them were employed in connection with the Christian rites, and many of the conceptions, particularly that of sharing in immortality by communion with deity, became an essential part of Christian doctrine. Thus the early idea of the services, as occasions for mutual edification through the interchange of spiritual gifts, gave way in course of time to the theory that they consisted of sacred and mysterious rites by means of which communion with God is promoted. The emphasis accordingly came to be laid increasingly upon the formal side of worship, and a value was given to the ceremonies as such, and their proper and correct performance by duly qualified persons, *i.e.*, ordained priests, was all-important. (See ORDER, HOLY.)

Doctrine.—Two tendencies appeared in the thought of the primitive Church, the one to regard Christianity as a law given by God for the government of men's lives, with the promise of a blessed immortality as a reward for its observance; the other to view it as a means by which the corrupt and mortal nature of man is transformed, so that he becomes a spiritual and holy being. The latter tendency appeared first in the New Testament in Paul, and afterwards in the Gospel and 1st Epistle of John. The former found expression in most of our New Testament writings, in all of the apostolic fathers except Ignatius, and in the Apologists of the 2nd century. The two tendencies were not always mutually exclusive, but the one or the other was predominant in every case. Towards the end of the 2nd century they were combined by Irenaeus, bishop of Lyons. To him salvation bears a double aspect, involving both release from the control of the devil and the transformation of man's nature by the indwelling of the Divine. Only he is saved who on the one hand is forgiven at baptism and so released from the power of Satan, and then goes on to live in obedience to the divine law, and on the other hand receives in baptism the germ of a new spiritual nature and is progressively transformed by receiving the body and blood of the divine Christ in the eucharist. This double conception of salvation and of the means thereto was handed down to the Church of subsequent generations and became fundamental in its thought.

The twofold conception referred to had its influence also upon thought about Christ. The effect of the legal view of Christianity was to make Christ an agent of God in the revelation of the divine will and truth, and so a subordinate being between God and the world, the Logos of current Greek thought. The effect of the mystical conception was to identify Christ with God in order that by His incarnation the divine nature might be brought into union with humanity and the latter be transformed. In this case too a combination was effected, the idea of Christ as the incarnation of the Logos or Son of God being retained and yet His deity being preserved by the assertion of the deity of the Logos. The recognition of Christ as the incarnation of the Logos was practically universal before the close of the 3rd century; but His deity was still widely denied, and the Arian controversy which distracted the Church of the 4th century concerned the latter question. At the council of Nicaea in 325 the deity of Christ received official sanction and was given formulation in the

original Nicene Creed. Controversy continued for some time, but finally the Nicene decision was recognized both in East and West as the only orthodox faith. The deity of the Son was believed to carry with it that of the Spirit, who was associated with Father and Son in the baptismal formula and in the current symbols, and so the victory of the Nicene Christology meant the recognition of the doctrine of the Trinity as a part of the orthodox faith.

The assertion of the deity of the Son incarnate in Christ raised another problem which constituted the subject of dispute in the Christological controversies of the 4th and following centuries. What is the relation of the divine and human natures in Christ? At the council of Chalcedon in 451 it was declared that in the person of Christ are united two complete natures, divine and human, which retain after the union all their properties unchanged. This was supplemented at the 3rd council of Constantinople in 680 by the statement that each of the natures contains a will, so that Christ possesses two wills. The Western Church accepted the decisions of Nicaea, Chalcedon and Constantinople, and so the doctrines of the Trinity and of the two natures in Christ were handed down as orthodox dogma in West as well as East.

Meanwhile in the Western Church the subject of sin and grace, and the relation of divine and human activity in salvation, received special attention; and finally, at the 2nd council of Orange in 529, after both Pelagianism and semi-Pelagianism had been repudiated, a moderate form of Augustinianism was adopted, involving the theory that every man as a result of the Fall is in such a condition that he can take no steps in the direction of salvation until he has been renewed by the divine grace given in baptism, and that he cannot continue in the good thus begun except by the constant assistance of that grace, which is mediated only by the Catholic Church. This decision was confirmed by Boniface II., and became the accepted doctrine in the Western Church of the middle ages.

Organization.—The origin and early development of ecclesiastical organization are involved in obscurity.

In the earliest days the Church was regarded as a divine institution, ruled not by men but by the Holy Spirit. At the same time it was believed that the Spirit imparted different gifts to different believers, and each gift fitted its recipient for the performance of some service, being intended not for his own good but for the good of his brethren (*cf.* 1 Cor. xii.; Eph. iv. 11). The chief of these was the gift of teaching, that is, of understanding and interpreting to others the will and truth of God. Those who were endowed more largely than their fellows with this gift were commonly known as apostles, prophets and teachers (*cf.* Acts xiii. 1; 1 Cor. xii. 28; Eph. ii. 20, iii. 5, iv. 11). The apostles were traveling missionaries or evangelists; there were many of them in the primitive Church, and only gradually did the term come to be applied exclusively to the twelve and Paul. There is no sign that the apostles, whether the twelve or others, held any official position in the Church: that they had a large measure of authority goes without saying, but it depended always upon their brethren's recognition of their possession of the divine gift of apostleship, and the right of Churches or individuals to test their claims and to refuse to listen to them if they did not vindicate their divine call was everywhere recognized. Witness, for instance, Paul's reference to false apostles in 2 Cor. xi. 13, and his efforts to establish his own apostolic character to the satisfaction of the Corinthians and Galatians (1 Cor. ix. 1 ff.; 2 Cor. x. 13; Gal. i. 8 ff.), and the reference in Rev. ii. 2 to the fact that the Church at Ephesus had tried certain men who claimed to be apostles and had found them false.

Between the apostles, prophets and teachers no hard-and-fast lines can be drawn. The apostles were commonly missionary prophets, called permanently or temporarily to the special work of evangelization (*cf.* Acts xiii. 1), while the teachers seem to have been distinguished both from apostles and prophets by the fact that their spiritual endowment was less strikingly supernatural. The indefiniteness of the boundaries between the three classes, and the free interchange of names, show how far they were from being definite offices or orders within the Church.

But at an early day we find regular officers in this and that

local Church, and early in the 2nd century the three permanent offices of bishop, presbyter and deacon existed at any rate in Asia Minor. Their rise was due principally to the necessity of administering the charities of the Church, putting an end to disorder and confusion in the religious services, and disciplining offenders. Regular officers within the local Churches gradually made their appearance, sometimes simply recognized as charged with responsibilities which they had already voluntarily assumed (*cf.* 1 Cor. xvi. 15), sometimes appointed by an apostle or prophet or other specially inspired man (*cf.* Acts xiv. 23; Titus i. 5; 1 Clement 44), sometimes formally chosen by the congregation itself (*cf.* Acts vi.). These men naturally acquired more and more, as time passed, the control and leadership of the Church in all its activities, and out of what was in the beginning more or less informal and temporary grew fixed and permanent offices, the incumbents of which were recognized as having a right to rule over the Church, a right which once given could not lawfully be taken away unless they were unfaithful to their trust. Not continued endowment by the Spirit, but the possession of an ecclesiastical office now became the basis of authority. The earliest expression of this genuinely official principle is found in Clement's Epistle to the Corinthians (ch. xlv.).

The earliest distinct evidence of the organization of Churches under a single head is found in the Epistles of Ignatius of Antioch, which date from the latter part of the reign of Trajan (c. 116). Ignatius bears witness to the presence in various Churches of Asia Minor of a single bishop in control, with whom are associated as his subordinates a number of elders and deacons. This form of organization ultimately became universal. Where there were one bishop and a number of presbyters and deacons in a church, the presbyters constituted the bishop's council, and the deacons his assistants in the management of the finances and charities and in the conduct of the services.

Meanwhile the rise and rapid spread of Gnosticism (*q.v.*) produced a crisis in the Church of the 2nd century, and profoundly affected the ecclesiastical organization. The views of the Gnostics, and of Marcion as well, seemed to the majority of Christians destructive of the gospel, and it was widely felt that they were too dangerous to be tolerated. The original dependence upon the Spirit for light and guidance was inadequate. The men in question claimed to be Christians and to enjoy divine illumination as truly as anybody, and so other safeguards appeared necessary. It was in the effort to find such safeguards that steps were taken which finally resulted in the institution known as the Catholic Church. The first of these steps was the recognition of the teaching of the apostles as the exclusive standard of Christian truth. This found expression in the formulation of our New Testament, and of an apostolic rule of faith, of which the old Roman symbol, the original of our present Apostles' Creed, is one of the earliest examples. Over against the claims of the Gnostics that they had apostolic authority, either oral or written, for their preaching, were set these two standards, by which alone the apostolic character of any doctrine was to be tested (*cf.* Irenaeus, *Adversus Haereses*, i. 10, iii. 3, 4; Tertullian, *De Prescriptione Haereticorum*). But these standards proved inadequate to the emergency, for it was possible, especially by the use of the allegorical method, to interpret them in more than one way, and their apostolic origin and authority were not everywhere admitted. In view of this difficulty, it was claimed that the apostles had appointed the bishops as their successors, and that the latter were in possession of special divine grace enabling them to transmit and to interpret without error the teaching of the apostles committed to them. This is the famous theory known as "apostolic succession." The idea of the apostolic appointment of church officers is as old as Clement of Rome, but the use of the theory to guarantee the apostolic character of episcopal teaching was due to the exigencies of the Gnostic conflict. Irenaeus (*op. cit.* iii. 3, iv. 26, 33, v. 20), Tertullian (*op. cit.*, 32) and Hippolytus (*Philosophumena*, bk. i., preface) are about our earliest witnesses to it, and Cyprian sets it forth quite clearly in his epistles. The Church was thus in possession not only of authoritative apostolic doctrine, but also of a permanent apostolic office, to which alone belonged the right to determine what that

doctrine is. The combination of this idea with that of clerical sacerdotalism completed the Catholic theory of the Church and the clergy. Saving grace is recognized as apostolic grace, and the bishops as successors of the apostles become its sole transmitters. Bishops are therefore necessary to the very being of the Church, which without them is without the saving grace for the giving of which the Church exists (*cf.* Cyprian, *Ep.* 33, "ecclesia super episcopos constituitur"; 66, "ecclesia in episcopo"; also *Ep.* 59, and *De unitate ecclesiae* 17).

These bishops were originally not diocesan but congregational, that is, each church, however small, had its own bishop. This is the organization testified to by Ignatius, and Cyprian's insistence upon the bishop as necessary to the very existence of the Church seems to imply the same thing. Congregational episcopacy was the rule for a number of generations. But after the middle of the 3rd century diocesan episcopacy began to make its appearance here and there, and became common in the 4th century under the influence of the general tendency toward centralization, the increasing power of city bishops, and the growing dignity of the episcopate (*cf.* canon 6 of the council of Sardica, and canon 57 of the council of Laodicea; and see Harnack, *Mission und Ausbreitung*, pp. 319 *seq.*). This enlargement of the bishop's parish and multiplication of the churches under his care led to a change in the functions of the presbyterate. So long as each church had its own bishop the presbyters constituted simply his council, but with the growth of diocesan episcopacy it became the custom to put each congregation under the care of a particular presbyter, who performed within it most of the pastoral duties formerly discharged by the bishop himself. The presbyters, however, were not independent officers. They were only representatives of the bishop, and the churches over which they were set were all a part of his parish, so that the Cyprianic principle, that the bishop is necessary to the very being of the Church, held good of diocesan as well as of congregational episcopacy.

The belief in the unity of the entire Church had existed from the beginning. Though made up of widely scattered congregations, it was thought of as one body of Christ, one people of God. This ideal unity found expression in many ways. Intercommunication between the various Christian communities was very active. Christians upon a journey were always sure of a warm welcome and hospitable entertainment from their fellow-disciples. Messengers and letters were sent freely from one church to another. Documents of various kinds, including gospels and apostolic epistles, circulated widely. Thus in various ways the feeling of unity found expression, and the development of widely separated parts of Christendom conformed more or less closely to a common type. It was due to agencies such as these that the scattered churches did not go each its own way and become ultimately separate and diverse institutions. But this general unity became official, and expressed itself in organization, only with the rise of the conciliar and metropolitan systems. Already before the end of the 2nd century local synods were held in Asia Minor to deal with Montanism, and in the 3rd century provincial synods became common, and by the council of Nicaea (canon 5) it was decreed that they should be held twice every year in every province. Larger synods representing the churches of a number of contiguous provinces also met frequently; for instance, in the early 4th century at Elvira, Ancyra, Neo-Caesarea and Arles, the last representing the entire Western world. Such gatherings were specially common during the great doctrinal controversies of the 4th century. In 325 the first general or oecumenical council, representing theoretically the entire Christian Church, was held at Nicaea. Other councils of the first period now recognized as oecumenical by the Church both East and West are Constantinople I. (381), Ephesus (431), Chalcedon (451), Constantinople II. (553). All these were called by the emperor, and to their decisions he gave the force of law. Thus the character of the Church as a State institution voiced itself in them (*see* COUNCIL).

The theory that the bishops are successors of the apostles, and as such the authoritative conservators and interpreters of apostolic truth, involves of course the solidarity of the episcopate, and the assumption that all bishops are in complete harmony and bear wit-

ness to the same body of doctrine. This assumption, however, has not always been sustained by the facts. Serious disagreements even on important matters developed frequently. As a result the oecumenical council came into existence especially for the purpose of settling disputed questions of doctrine, and giving to the collective episcopate the opportunity to express its voice in a final and official way. At the council of Nicaea, and at the oecumenical councils which followed, the idea of an infallible episcopate giving authoritative and permanent utterance to apostolic and therefore divine truth, found clear expression, and has been handed down as a part of the faith of the Catholic Church both East and West.

Meanwhile the Roman episcopate developed into the papacy, which claimed supremacy over the entire Christian Church, and actually exercised it increasingly in the West from the 5th century on. This development was forwarded by Augustine, who in his famous work *De civitate Dei* identified the Church with the Kingdom of God, and claimed that it was supreme over all the nations of the earth, which make up the *civitas terrena* or earthly state. Augustine's theory was ultimately accepted everywhere in the West, and thus the Church of the middle ages was regarded not only as the sole ark of salvation, but also as the ultimate authority, moral, intellectual and political. Upon this doctrine was built, not by Augustine himself but by others who came after him, the structure of the papacy, the bishop of Rome being finally recognized as the head under Christ of the *civitas Dei*, and so the supreme organ of divine authority on earth (*see* PAPACY and POPE).

B. THE CHRISTIAN CHURCH IN THE MIDDLE AGES

The middle ages came into being at the time when the political structure of the world, based upon the conquests of Alexander the Great and the achievements of Julius Caesar, began to disintegrate. They were present when the believers in Mohammed held sway in provinces which Alexander had brought under the influence of Hellenism; while the Lombards, the West Goths, the Franks and the Anglo-Saxons had established kingdoms in Italy, Spain, Gaul and Britain.

The East.—Ancient and mediaeval times were not separated by so deep a gulf in the East as in the West; for in the East the Empire continued to exist, although within narrow limits, until towards the end of the middle ages. Constantinople only fell in 1453. Ecclesiastical Byzantinism is therefore not a product of the middle ages; it is the outcome of the development of the eastern half of the empire from the time of Constantine the Great. Imperial power extended equally over State and Church. Since the emperor ruled the Church there was no longer any question of independence for the bishops.

The *orthodoxy* of the Eastern Church was also a result of the Church's development after the time of Constantine. In the long strife over dogma the old belief of the Greeks in the value of knowledge had made itself felt, and this faith was not extinct in the Eastern Church. But the strife over dogma ended with the 7th century. After the termination of the Monothelite controversy (638–680), creed and doctrines were complete; it was only necessary to preserve them intact. Theology, therefore, now resolved itself into the collection and reproduction of the teaching of ancient authorities. The great dogmatist of the Eastern Church, John of Damascus (c. 699–753), who stood on the threshold of the middle ages, formulated clearly and precisely his working principle: to put forward nothing of his own, but to present the truth according to the authority of the Bible and of the Fathers of the Church.

In the Eastern Church the religious interest concerned itself more keenly with the mystic rites of divine worship than with dogma. Here was more than knowledge; here were representations of a mystic sensuousness, solemn rites, which brought the faithful into immediate contact with the Divine, and guaranteed to them the reception of heavenly powers. We may gauge the energy with which the Greek intellect turned in this direction if we call to mind that the controversy about dogma was replaced by the controversy about images. This raged in the Eastern Church for more than a century (726–843), and only sank to rest when the

worship of images was unconditionally conceded. In this connection the image was not looked upon merely as a symbol, but as the vehicle of the presence and power of that which it represented.

Consistent with this circle of ideas is the cultivation of religious experience. A beginning had been made, in the 5th century, by the Neo-platonic Christian who addressed his contemporaries under the mask of Dionysius the Areopagite. He is the first of a series of theological mystics which continued through every century of the middle ages. It is this striving after religious experience that gives to the Oriental *monasticism* (*q.v.*) of the middle ages its peculiar character; in it the old Hellenic ideal of the wise man who has no wants, *αὐτάρκεια*, was from the first fused with the Christian conception of unreserved self-surrender to God as the highest aim and the highest good.

The Eastern Church, then, throughout the middle ages, remained true in every particular to its ancient character. It did not develop as did the Western Church during this period, but room for *expansion* was found in the new nations which had sprung into existence since the beginning of the middle ages: the Bulgarians, the Serbians, and the multifarious peoples grouped under the name of Russians. One outcome of this expansion was the impossibility of continuing to share the life of the Western Church. Neither in the East nor in the West was a *separation* desired; but it was inevitable, since the lives of East and West were moving in different directions.

Since the time when the church of eastern Syria had decided, in opposition to the church of the Empire, to cling to the ancient views of Syrian theologians—therefore also to the teaching and person of Nestorius—her relations were broken off with the church in western Syria and in Greek and Latin countries; but the power of *Nestorian* Christianity was not thereby diminished. Separated from the West, it directed its energies towards the East, and here its nearest neighbour was the Persian church. The latter followed, almost without opposition, the impulse received from Syria; from the rule of the patriarch Babaeus (498–503) it may be considered definitely Nestorian. Thus there survived in mid-Asia a widely-scattered remnant, which, although out of touch with the ancient usages of Christian civilization, yet in no way lacked higher culture. Nestorian philosophers and medical practitioners became the teachers of the great Arabian natural philosophers of the middle ages, and the latter obtained their knowledge of Greek learning from Syriac translations of the works of Greek thinkers.

Political conditions at the beginning of the middle ages favoured the Nestorian church, and the fact that the Arabs had conquered Syria, Palestine and Egypt, made it possible to exert an influence on the Christians in these countries. Of still more importance was the brisk commercial intercourse between central Asia and the countries of the Far East; for this led the Nestorians into China. But with the consolidation of Mohammedan power the greater part of Nestorian Christendom was swallowed up by Islam, and only remnants of this once extensive church have survived until modern times. The middle ages were even more disastrous for *Monophysite* Christianity; in their case there was no alternation of rise and decline, and there is only a long period of gradual exhaustion to chronicle, alike in Syria and in Egypt.

The West.—(i.) During the *early middle ages* the central fact in the history of the Church is the influence of the foundation of the Teutonic States. While the Eastern Church was stereotyping those peculiar characteristics which made her a thing apart, the Church of the West was brought face to face with the greatest revolution that Europe has ever experienced. At the end of the 6th century all the provinces of the Empire had become independent kingdoms, in which conquerors of Germanic race formed the dominant nationality. This is the great fact which stands out at the beginning of the history of the Church in the middle ages. The continuity of the political history of Europe was violently interrupted by the Germanic invasion, but not that of the history of the Church. Creed and dogma, above all, remained unchanged. The doctrinal decisions of the ancient Church remained the inde-

structible canon of belief, and what the theologians of the ancient Church had taught was revered as beyond improvement. The entire form of divine worship remained therefore unaltered. Even where the Latin tongue was not understood by the people, the Church preserved it in the mass and in the administration of the sacraments, in her exorcisms and in her benedictions. The organization of ecclesiastical offices; and the property and social status of the Church and of the hierarchy, remained unchanged.

Nevertheless, the new conditions did exercise the strongest influence upon the character of the Church. The churches of the Lombards, West Goths, Franks and Anglo-Saxons, all counted themselves parts of the Catholic Church; but the Catholic Church had altered its condition; it lacked the power of organization, and split up into territorial churches. Under the Empire the oecumenical council had been looked upon as the highest representative organ of the Catholic Church; but the earlier centuries of the middle ages witnessed the convocation of no oecumenical councils. Under the Empire the bishop of Rome had possessed in the Church an authority recognized and protected by the State; among the new territorial churches, respect for Rome and for the successor of Peter was not forgotten but had altered in character; legal authority had become merely moral authority; its wielder could exhort, warn, advise, but could not command. The bishops continued to meet in synods as before, but the councils became territorial synods; they were called together at irregular intervals by the king, and their decisions obtained legal effect only by royal sanction.

In the middle ages the *civilizing task of the Church* was first approached in England. Aldhelm (d. 709) and the Venerable Bede (d. 735) were the first scholars of the period. England was also the home of Winfrid Bonifatius (St. Boniface, d. c. 757), who, in co-operation with the bishops of Rome, began the reorganization of the Frankish church, which had fallen into confusion and decay during the political disorders of the last years of the Merovingians. It was Boniface, too, who, with the aid of numerous English priests, monks and nuns, introduced the literary culture of England into Germany.

Charlemagne (d. 814) built on the foundations laid by St. Boniface. The importance of Charlemagne's work, from the point of view of the Church, consists in his having led back the Frankish Church to the fulfilment of her functions as a religious and civilizing agent. This was the purpose of his ecclesiastical legislation. The principal means to this end taken by him was the raising of the status of the clergy. For the purpose of carrying out his ideas Charlemagne gathered round him the best intellects of Europe. None was more intimately associated with him than the Anglo-Saxon Alcuin (d. 804); but he was only one among many. Under this guidance theology flourished in the Frankish empire. It was as little original as that of Bede; for on the continent, too, scholars were content to think what those of old had thought before them. But in so doing they did not only repeat the old formulae; the ideas of the men of old sprang into new life. This is shown by the searching discussions to which the Adoptionist controversy gave rise. At the same time, the controversy with the Eastern Church over the adoration of images shows that the younger Western theology felt itself equal, if not superior to the Greek.

The second generation of Frankish theologians did not lag behind the first. Hrabanus of Fulda (who died archbishop of Mainz in 856) was in the range of his knowledge undoubtedly Alcuin's superior. He was the first learned theologian produced by Germany. His disciple, Abbot Walafrid Strabo of Reichenau (d. 849), was the author of the *Glossa Ordinaria*, a work which formed the foundation of biblical exposition throughout the middle ages. France was still more richly provided with theologians in the 9th century: her most prominent names are Hincmar, archbishop of Reims (d. 882), Bishop Prudentius of Troyes (d. 861), the monks Servatus Lupus (d. 862), Radbert Paschasius (d. c. 860), and Ratramnus (d. after 868); and the last theologian who came into France from abroad, Johannes Scotus Erigena (d. c. 880). The real strength of Erigena was in the field of speculative metaphysics: the controversy about

predestination, which, in the 9th century, Hincmar and Hrabanus fought out with the monk Gottschalk of Fulda, as well as the discussions that arose from the definition of the doctrine of transubstantiation by Radbert, enable us to gauge the intellectual energy with which theological problems were being handled.

Charlemagne followed his father's policy in carrying out his ecclesiastical measures in close association with the bishops of Rome. The relation was one of co-operation, without supremacy on either side. There were, indeed, forces tending in the contrary direction; and these were present in the Frankish empire. Evidence of this is given by the canon law forgeries of the 9th century: especially the great collection of the Pseudo-Isidorian Decretals (*see* DECRETALS), the fundamental idea being that all lay control in ecclesiastical affairs is wrong. For the moment, however, this party met with no success. Of more importance was the fact that at Rome the old conditions, the old claims, and the old law were unforgotten. For example, Nicholas I. (858-867) drew a picture of the divine right and unlimited power of the bishop of Rome, which anticipated all that the greatest of his successors were, centuries later, actually to effect. The time had not, however, yet come for the establishment of the papal world-dominion. For, while the power of Charlemagne's successors was decaying, the papacy itself became involved in the confusion of the party strife of Italy and of the city of Rome, and was plunged in consequence into such an abyss of degradation (the so-called Pornocracy), that it was in danger of forfeiting every shred of its moral authority over Christendom.

(ii.) During the central period of the Middle Ages the antagonism between the German conception of ecclesiastical affairs and Roman views of ecclesiastical law found inevitable expression. This was most obvious in the matter of appointment to bishoprics. At Rome canonical election was alone regarded as lawful; in Germany, on the other hand, developments since the time of Charlemagne had led to the actual appointment of bishops being in the hands of the king, although the form of ecclesiastical election was preserved.

The practice customary in Germany was finally transferred to Rome itself. The desperate position of the papacy in the 11th century obliged Henry III. to intervene. When, in Dec. 1046, after three rival popes had been set aside, he nominated Suidgar, bishop of Bamberg, as bishop of Rome before all the people in St. Peter's, the papacy was bestowed in the same way as a German bishopric; and what had occurred in this case was to become the rule. By procuring the transference of the patriciate from the Roman people to himself Henry assured his influence over the appointment of the popes, and accordingly also nominated the successors of Clement II.

His intervention saved the papacy. For the popes nominated by him, Leo IX. in particular, were men of high character, who exercised their office in a loftier spirit than their corrupt predecessors. They placed themselves at the head of the movement for ecclesiastical reform. But it was not possible for the relation between Empire and Papacy to remain what Henry III. had made it.

The original sources of this reform movement lay far back, in the time of the Carolingians. It has been pointed out how Charlemagne pressed the monks into the service of his civilizing aims; but he thereby alienated monasticism from its original ideals. These, however, had far too strong a hold upon the Roman world for a reaction against the new tendency to be long avoided. This reaction began with the reform of Benedict of Aniane (d. 821), the aim of which was to bring the Benedictine order back to the principles of its original rules. In the next century the reform movement acquired a fresh centre in the Burgundian monastery of Cluny. A large number of the reformed monasteries attached themselves to the congregation of Cluny, thus assuring the influence of reformed monasticism upon the Church, and securing likewise its independence of the diocesan bishops, since the abbot of Cluny was subordinate of the pope alone (*see* CLUNY, BENEDICTINES, and MONASTICISM). Everywhere the object was the same: the supreme obligation of the Rule, the renewal of discipline, and also the economic improvement of the monasteries.

The reform movement had originally no connection with ecclesiastical politics; but that came later when the leaders turned their attention to the abuses prevalent among the clergy, to the conditions obtaining in the Church in defiance of the ecclesiastical law. "Return to the canon law!" was now the battle-cry. The programme of reform thus included the freeing of the Church from the influence of the State, the recovery of her absolute control over all her possessions, the liberty of the Church and of the hierarchy.

As a result, the party of reform placed itself in opposition to those ecclesiastical conditions which had arisen since the conversion of the Teutonic peoples. It was, then, a fact pregnant with the most momentous consequences that Leo IX. attached himself to the party of reform. For, thanks to him and to the men he gathered round him (Hildebrand, Humbert and others), their principles were established in Rome, and the pope himself became the leader of ecclesiastical reform. But the carrying out of reforms led at once to dissensions with the civil power, the starting-point being the attack upon simony, this term covering all transferences by laymen of ecclesiastical offices or benefices, even though no money changed hands in the process. Thus the lord who handed over a living was a simonist, and so too was the king who invested a bishop. The Church at first concentrated her attack upon investiture. In 1059 the new system of papal election introduced by Nicholas II. (*see* CONCLAVE) ensured the occupation of the Holy See by a pope favourable to the party of reform; and in 1078 Gregory VII. issued his prohibition of lay investiture. In the years of conflict that followed Gregory looked far beyond this point; he set his aim ever higher, until, in the end, his idea was to concentrate all ecclesiastical power in the hands of the pope, and to raise the papacy to the dominion of the world. Thus was to be realized the old dream of Augustine: that of a Kingdom of God on earth under the rule of the Church. But it was not given to Gregory to reach this goal, and his successors had to return again to the strife over investiture; and the long struggle ended in a compromise by the Concordat of Worms (1122), the essential part of which was that the Empire accepted the canonical election of bishops, while the Church acknowledged that the bishop held his temporal rights from the Empire, and was therefore to be invested with them by a touch from the royal sceptre. A similar solution was arrived at in England. In France the demands of the Church were successful to the same degree as in England and Germany, but without any conflict. Thus the Germanic element in the law regarding appointment to bishoprics was eliminated. Somewhat later it disappeared also in the case of the churches of less importance, patronal rights over these being substituted for the former absolute ownership. The pontificate of Alexander III. (1159-81) decided this.

The Teutonic peoples had been taking the lead in the expansion of Christianity; but the spirit of the Latin races now began to assert itself. Scholasticism, the new theology, had its home in the Latin countries. Reason as well as authority had been appealed to as the foundation of theology; but for the theologians of the 9th and 10th centuries, whose method had been merely that of restatement, *ratio* and *auctoritas* were in perfect accord. Then Berengar of Tours (d. 1088) ventured to set up reason against authority: by reason the truth must be decided. This involved the question of the relation in theology of authority and reason, and of whether the theological method is authoritative or rational. To these questions Berengar gave no answer; he was ruined by his opposition to Radbert's doctrine of transubstantiation. The Lombard Anselm (d. 1109), archbishop of Canterbury, was the first to deal with the subject. He took as his starting-point the traditional faith; but he was convinced that whoever has experience of the truths of the faith would be able to understand them, by the exercise of his natural reason.

It was a bold conception—too bold for the mediaeval world, for which faith was primarily the obligation to believe. It was easy, therefore, to understand why Anselm's method did not become the dominant one in theology. Not he, but the Frenchman Abelard (d. 1142), was the creator of the scholastic method. Abelard, too, started from tradition; but he discovered that the statements of

the various authorities are very often in the relation of *sic et non*, yes and no. Upon this fact he based his pronouncement as to the function of theology: it must employ the dialectic method to reconcile the contradictions of tradition, and thus to shape the doctrines of the faith in accordance with reason. By teaching this method Abelard created the implements for the erection of the great theological systems of the schoolmen of the 12th and 13th centuries: Peter Lombard (d. 1160), Alexander of Hales (d. 1245), Albertus Magnus (d. 1280) and Thomas Aquinas (d. 1275). They adventured a complete exposition of Christian doctrine that should be altogether ecclesiastical and at the same time altogether rational. In so doing they set to work to complete the development of ecclesiastical dogma; the formulation of the Catholic doctrine of the Sacraments was the work of scholasticism.

Canon law is the twin-sister of scholasticism. At the very time when Peter Lombard was shaping his Sentences, the monk Gratian of Bologna was making a new collection of laws. It was not only significant that in the *Concordia discordantium canonum* ecclesiastical laws, whether from authentic or forged sources, were gathered together without regard to the existing civil law; of even greater eventual importance was the fact that Gratian taught that the contradictions of the canon law were to be reconciled by the same method as that used by theology to reconcile the discrepancies of doctrinal tradition. Thus Gratian became the founder of the science of canon law, a science which, like the scholastic theology, was entirely ecclesiastical and entirely rational (*see* CANON LAW).

Like the new theology and the new science of law, the new monasticism was also rooted in Latin soil. The duty of the priest-monk is not only to work out his own salvation, but, by preaching and cure of souls, to labour for others. This was the dominant idea of the order of friars preachers founded in 1216 by St. Dominic (*see* DOMINIC; DOMINICANS). It was also the basis of the order of friars minor, founded in 1210 (*see* FRANCIS OF ASSISI; FRANCISCANS). This alone would serve to indicate the remarkable deepening of the religious life that had taken place in the Latin countries. In the 12th century the most influential exponent of this new piety was Bernard of Clairvaux (*q.v.*), who taught men to find God by leading them to Christ. Contemporary with him were Hugh of St. Victor (*q.v.*) and his pupil Richard of St. Victor (*q.v.*), both monks of the abbey of St. Victor at Paris, the aim of whose teaching was a mystical absorption of thought in the Godhead and the surrender of self to the Eternal Love. Under the influence of these ideas, in part purely Christian and in part Neoplatonic, piety gained in warmth and depth and became more personal; and though at first it flourished in the monasteries, and in those of the mendicant orders especially, it penetrated far beyond them and influenced the laity everywhere. The new piety did not set itself in opposition either to the hierarchy or to the institutions of the Church, such as the sacraments and the discipline of penance, nor did it reject those foreign elements (asceticism, worship of saints and the like) which had passed of old time into Christianity from the ancient world. Its temper was not critical, but aggressively practical.

All this meant a mighty exaltation of the Church, which ruled the minds of men as it had hardly ever done before. Nor was it possible that the position of the bishop of Rome, the supreme head of the Western Church, should remain unaffected by it. Two of the most powerful of the German emperors, Frederick I. and his son Henry VI., struggled to renew and to maintain the imperial supremacy over the papacy. But when at the peace of Venice (1177) Frederick recognized Alexander III. as pope, he relinquished the hope of carrying out his Italian policy; while Henry died at the early age of thirty-two (1197), before his far-reaching schemes had been realized.

The field was thus cleared for the full development of papal power. This had greatly increased since the Concordat of Worms, and reached its height under Innocent III. (1198-1216). Innocent believed himself to be the representative of God, and as such the supreme possessor of both spiritual and temporal power. He therefore claimed in both spheres the supreme

administrative, legislative and judicial authority. The bishops described themselves as holding office "by grace of the Apostolic See," for they administered their dioceses as plenipotentiaries of the pope; and even the criminal jurisdiction of the church (*see* INQUISITION) became more and more concentrated in his hands. And just as he considered himself entitled to appoint to all ecclesiastical offices, so also he invested the emperor with his empire and kings with their kingdoms. Not only did he despatch his decretals to the universities to form the basis of the teaching of the canon law and of the decisions founded upon it, but he considered himself empowered to annul civil laws. Thus he annulled the Great Charter in 1215. Just as the Curia was the supreme court of appeal in ecclesiastical causes, so also the pope threatened disobedient princes with deposition, *e.g.*, the emperor Otto IV. in 1210, and John of England in 1212. But the papal claim to supreme temporal authority proved impossible to maintain, although Innocent III. had apparently enforced it. The long struggle against Frederick II., carried on by Gregory IX. (1227-41) and Innocent IV. (1243-54), did not result in victory; no papal sentence, but only death itself, deprived the emperor of his dominions; and when Boniface VIII. (1294-1303), who gave the papal claims to universal dominion their classical form, quarrelled with Philip IV. of France about the extension of the royal power, he could not but perceive that the national monarchy had become a force which it was impossible for the papacy to overcome.

(iii.) At the close of the middle ages we come to a period of disintegration. While the Church was yet at the height of her power began the great revolution which was to end in the disruption of that union between the Temporal and the Spiritual which, under her dominion, had characterized the life of the West. The Temporal now claimed its proper rights. The political power of the Empire, indeed, had been shattered; but this left all the more room for the vigorous development of national states, notably of France and England. At the same time intellectual life was enriched by a wealth of fresh views and new ideas, partly the result of the busy intercourse with the East to which the Crusades had given the first impetus, and which had been strengthened and extended by lively trade relations, partly of the revived study, eagerly pursued, of ancient philosophy and literature (*see* RENAISSANCE). The life of the Church, moreover, was affected by the economic changes due to the rise of the power of money as opposed to the old economic system based upon land.

The effects of these changes made themselves felt on all sides, in no case more strongly than in that of the papal claims to the supreme government of the world. Theoretically they were still unwaveringly asserted; but after Boniface VIII. no pope seriously attempted to realize them; to do so had in fact become impossible, for from the time of their residence at Avignon (1305-77) the popes were in a state of complete dependence upon the French crown. In France Philip IV.'s jurists maintained that the temporal power was independent of the spiritual. In Italy, a little later, Dante championed the divine right of the emperor (*De Monarchia*, 1311). In Germany, Marsiglio of Padua and Jean of Jandun, the literary allies of the emperor Louis IV., ventured to define anew the nature of the civil power from the standpoint of natural law, and to assert its absolute sovereignty (*Defensor pacis*, c. 1352); while the Franciscan William of Occam (d. 1349) examined, also in Louis' interests, into the nature of the relation between the two powers. He too concluded that the temporal power is independent of the spiritual, and is even justified in invading the sphere of the latter in cases of necessity.

While these thoughts were filling men's minds, opposition to the papal rule over the Church was also gaining continually in strength. The reasons for this were numerous, first among them being the abuses of the papal system of finance, which had to provide funds for the vast administrative machinery of the Curia. There was also the boundless abuse and arbitrary exercise of the right of ecclesiastical patronage; and further the ever-increasing traffic in dispensations, the abuse of spiritual punishments for worldly ends, and so forth. No means, however, existed of enforcing any remedy until the papal schism occurred in 1378. Such a schism as this, so intolerable to the ecclesiastical sense of the

middle ages, necessitated the discovery of some authority superior to the rival popes, and therefore able to put an end to their quarrelling. General councils were now once more called to mind; but these were no longer conceived as mere advisory councils to the pope, but as the highest representative organ of the universal Church, and as such ranking above the pope, and competent to demand obedience even from him. The council of Constance (1414-18) did actually put an end to the schism; but the reforms begun at Constance and continued at Basel (1431-49) proved insufficient. Above all, the attempt to set up the general council as an ordinary institution of the Catholic Church failed; and the Roman papacy, restored at Constance, preserved its irresponsible and unlimited power over the government of the Church (*see* PAPACY; CONSTANCE, COUNCIL OF; and BASEL, COUNCIL OF). Neither France nor Germany, however, was prepared to forgo the reforms passed by the council. France secured their validity, as far as she herself was concerned, by the Pragmatic Sanction of Bourges (July 7, 1438); Germany followed with the Acceptation of Mainz (March 26, 1439). The theory of the papal supremacy held by the Curia was thus at least called in question.

The antagonism of the opposition parties was even more pronounced. The tendencies which they represented had been present when the middle ages were yet at their height; but the papacy, while at the zenith of its power, had succeeded in crushing the attacks made upon the creed of the Church by its most dangerous foes, the dualistic Cathars (*q.v.*), Waldenses (*q.v.*) and kindred enthusiasts, who everywhere kept alive mistrust of the temporal power of the Church, of her priesthood and her hierarchy. In England the hierarchy was attacked by Wycliffe (*d.* 1384), its greatest opponent before Luther. Starting from Augustine's conception of the Church as the community of the elect, he protested against a church of wealth and power, a church that had become a political institution instead of a school of salvation; and against its head, the bishop of Rome. Wycliffe's ideas, conveyed to the continent, precipitated the outbreak of the Hussite storm in Bohemia (*see* HUSS; WYCLIFFE; LOLLARDS). This was open opposition; but there was besides another opposing force which, though it raised no noise of controversy, was far more widely severed from the views of the Church than either Wycliffe or Huss, namely the Renaissance, which began its reign in Italy during the 14th century. The Renaissance meant the emancipation of the secular world from the domination of the Church, and it contributed in no small measure to the rupture of the educated class with ecclesiastical tradition. Beauty of form alone was at first sought, and found in the antique; but, with the form, the spirit of the classical attitude towards life was revived. The men of the Renaissance wished to enjoy the earth by means of secular education and culture, and an impassable gulf yawned between their views of religion and morality and those of the Church. Theology could no longer provide a reconciliation. Since the time of Duns Scotus (*d.* 1308) theologians had been conscious of the discrepancy between Aristotelianism and ecclesiastical dogma. Faith in the infallibility of the scholastic system was thus shaken, and the system itself was destroyed by the revival of philosophic nominalism, which had been discredited in the 11th century by the realism of the great schoolmen. It now found a courageous supporter in William of Occam, and through him became widely accepted. But nominalism was powerless to inspire theology with new life; on the contrary, its intervention only increased the inextricable tangle of the hairsplitting questions with which theology busied itself.

In the meantime the Roman claim to the supreme government of the Church was steadily maintained. In 1512 Julius II. called together the 5th Lateran general council, which expressly recognized the subjection of the councils to the pope and also declared the constitution of Boniface VIII. (*see* above) valid in law. But the papacy that sought to win back its old position was no longer the same as of old. Eugenius IV.'s successor, Nicholas V. (1447-55), was the first of the Renaissance popes. Under his successors the views which prevailed at the secular courts of the Italian princes came likewise into play at the Curia: the papacy became an Italian principedom. Innocent VIII., Alexander VI., Julius II.

were in many respects remarkable men, but they were scarcely affected by the convictions of the Christian faith. The terrible tragedy which was consummated on May 23, 1498, before the Palazzo Vecchio, in Florence, casts a lurid light upon the irreconcilable opposition in which the wearers of the papal dignity stood to mediaeval piety; for Savonarola was in every fibre a loyal son of the mediaeval Church.

Twenty years after Savonarola's death Luther made public his theses against indulgences. The Reformation which thus began brought the disintegrating process of the middle ages to an end, and at the same time divided Western Catholicism in two. Yet we may say that this was its salvation; for the struggle against Luther drove the papacy back to its ecclesiastical duties, and the council of Trent established mediaeval dogma as the doctrine of modern Catholicism in contradistinction to Protestantism.

C. THE MODERN CHURCH

The issue in 1564 of the canons of the council of Trent marks a very definite epoch in the history of the Christian Church. Up till that time, in spite of the schism of East and West and of innumerable heresies, the idea of the Church as Catholic, not only in its faith but in its organization, had been generally accepted. From this conception the Reformers had, at the outset, no intention of departing. Their object had been to purify the Church of mediaeval accretions, and to restore the primitive model in the light of the new learning; the idea of rival "churches," differing in their fundamental doctrines and in their principles of organization, existing side by side, was as abhorrent to them as to the most rigid partisan of Roman centralization. The actual divisions of Western Christendom are the outcome, less of the purely religious influences of the Reformation period than of the political forces with which they were associated and confused. Thus over a great part of Europe the Catholic Church was split up into territorial or national churches, which, whatever the theoretical ties which bound them together, were in fact separate organizations, tending ever more and more to become isolated and self-contained units with no formal intercommunion, and, as the rivalry of nationalities grew, with increasingly little even of intercommunication.

It was not, indeed, till the settlement of Westphalia in 1648, after the Thirty Years' War, that this territorial division of Christendom became stereotyped, but the process had been going on for 100 years previously; in some States, as in England and Scotland, it had long been completed; in others, as in S. Germany, Bohemia and Poland, it was defeated by the political and missionary efforts of the Jesuits and other agents of the counter-Reformation. In any case, it received a vast impetus from the action of the council of Trent. With the issue of the Tridentine canons, all hope even of compromise between the "new" and the "old" religions was definitely closed. Considered from the standpoint of the world outside, the Roman Church is, no less than the Protestant communities, merely one of the sects into which Western Christendom has been divided—the most important and widespread, it is true, but playing in the general life and thought of the world a part immeasurably less important than that filled by the Church before the Reformation, and one in no sense justifying her claim to be considered as the sole inheritor of the tradition of the pre-Reformation Church.

If this be true of the Roman Catholic Church, it is still more so of the other great communities and confessions which emerged from the controversies of the Reformation. Of these the Anglican Church held most closely to the tradition of Catholic organization; but she has never made any higher claim than to be one of "the three branches of the Catholic Church," a claim repudiated by Rome and never formally admitted by the Church of the East. The Protestant churches established on the continent, even where—as in the case of the Lutherans—they approximate more closely than the official Anglican Church to Roman doctrine and practice, make no such claim. The Bible is for them the real source of authority in doctrine; their organization is part and parcel of that of the State. They are, in fact, the State in its religious aspect, and as such are territorial or national, not Catholic. This tendency has been common in the East also, where with the growth

of racial rivalries the Orthodox Church has split into a series of national churches, holding the same faith but independent as to organization.

A yet further development, of comparatively recent growth, has been the formation of what are now commonly called in England the "free churches." These represent a theory of the Church practically unknown to the Reformers, and only reached through the necessity for discovering a logical basis for the communities of conscientious dissidents from the established churches. According to this the Catholic Church is not a visibly organized body, but the sum of all "faithful people" throughout the world, who group themselves in churches modelled according to their convictions or needs. For the organization of these churches no divine sanction is claimed, though all are theoretically modelled on the lines laid down in the Scriptures. It follows that, while in the traditional Church, with its claim to an unbroken descent from a divine original, the individual is subordinate to the Church, in the "free churches" the Church is in a certain sense secondary to the individual. The believer may pass from one community to another without imperilling his spiritual life, or establish a new church without necessarily incurring the reproach of schism. From this theory, powerful in Great Britain and her colonies, supreme in the United States of America, has resulted an enormous multiplication of sects.

Hence, from the period of the Reformation onward, no historical account of the Christian Church as a whole, and considered as a definite institution, is possible. The stream of continuity has been broken, and divides into innumerable channels. The only possible synthesis is that of the Christianity common to all; as institutions, they are divided, though they possess many features in common. The history of the various branches of the Christian Church since the Reformation will therefore be found under their several titles: ROMAN CATHOLIC CHURCH; ENGLAND, CHURCH OF; PRESBYTERIANISM; CONGREGATIONALISM; METHODISM; and others. The references given under the titles CHRISTIANITY, HERESY, and REUNION, may be mentioned here also.

The first real Church History was written by Eusebius of Caesarea in the early part of the 4th century. His work was continued in the 5th century by Philostorgius, Socrates, Sozomen and Theodoret, and later by Evagrius, Theophanes and others. In the West the history of Eusebius was translated into Latin by Rufinus and continued to the end of the 4th century. In the 6th century Cassiodorus had a translation made of the histories of Socrates, Sozomen and Theodoret, and brought down to 518. It was called *Historia Ecclesiastica Tripartita*, and during the middle ages was the principal textbook of Church History in the West. During the 5th, 6th and following centuries numerous works were produced containing more or less ecclesiastical material: biographies, chronicles, cloister annals and especially many local and territorial histories such as Gregory of Tours, *History of the Franks*, and Bede's *Ecclesiastical History of England*. The Protestant Reformation led to a new development of historical writing. In 1559 and following years a number of Protestant scholars published the *Magdeburg Centuries* to prove the primitive character of Protestantism, and were followed by Baronius (*Annales Ecclesiastici*, 1588 ff.) on the Roman Catholic side. Both works became the model for many others.

Church history began to be written in a genuinely scientific spirit in the 18th century under the leadership of Mosheim, whose most important work is his *Institutiones Historiae Ecclesiasticae* (1755), and was carried further through the new historical spirit of the 19th century in a series of works of which the most important are those of Gieseler, *Lehrbuch der Kirchengeschichte* (1826 ff. Eng. tr. by H. B. Smith), with copious citations from the sources, and still valuable; Neander, *Allgemeine Geschichte der Christlichen Religion und Kirche* (1825 ff., Eng. tr. by Torrey), with special stress on the religious side of the subject (cf. also Schaff, *History of the Christian Church*, 5th ed. 1889 ff.); Ferdinand Christian Baur of Tübingen (*Das Christentum und die christliche Kirche*, 1853 ff.) whose many historical works were dominated by the principles of the Hegelian philosophy and exhibit both the merits and defects of that school; and Albrecht

Ritschl (*Entstehung der alt katholischen Kirche*, 2nd ed. 1857), who broke away from the Tübingen school and built up new points of view. Among many more recent books may be mentioned that of W. Moeller, *Lehrbuch der Kirchengeschichte* (1889 ff., 2nd ed. by von Schubert, 1898 ff., enlarged and improved), the translation of the latter being still the most useful textbook in English. Many references to historical works on specific branches of the subject will be found in the relative articles.

There are many editions of the works of the Fathers in the original, the most convenient, in spite of its defects, being that of J. P. Migne (*Patrologia Graeca*, 166 vols., Paris, 1857 ff.; *Patrologia Latina*, 221 vols., 1844 ff.). Of modern critical editions, besides those containing the works of one of another individual, the best are the Berlin edition of the early Greek Fathers (*Die griechischen christlichen Schriftsteller der ersten drei Jahrhunderte*, 1897 ff.), and the Vienna edition of the Latin Fathers (*Corpus scriptorum ecclesiasticorum Latinorum*, 1867 ff.), both of first-rate importance. There is a convenient English translation of most of the writings of the ante-Nicene Fathers by Roberts and Donaldson (*Ante-Nicene Christian Library*, 25 vols., Edinburgh, 1868 ff., American reprint, 9 vols., 1886 ff.). A continuation of it, containing selected works of the Nicene and post-Nicene period, was edited by Schaff and others under the title *A Select Library of Nicene and post-Nicene Fathers* (series 1 and 2; 28 vols., Buffalo and N.Y., 1886 ff.).

On early Christian literature, in addition to the works on Church history, see especially the monumental *Geschichte der altchristlichen Litteratur bis Eusebius*, by Harnack (1893 ff.). The brief *Geschichte der altchristlichen Litteratur in den ersten drei Jahrhunderten*, by G. Krüger (1895, English translation, 1897) is a very convenient summary. Bardenheuer's *Patrologie* (1894) and his *Geschichte der altkirchlichen Litteratur* (1902 ff.) should also be mentioned.

Upon the spread of the Church during the early centuries see especially Harnack, *Mission und Ausbreitung des Christentums in den ersten drei Jahrhunderten*, Eng. tr. *The Mission and Expansion of Christianity* (1907). An interesting parallel to the spread of Christianity in the Roman empire is afforded by the contemporary Mithraism; see Cumont's *Les Mystères de Mithra* (1900, Eng. tr., 1903). See also Hatch, *Influence of Greek Ideas and Usages upon the Christian Church*, 1890; Anrich, *Das antike Mysterienwesen in seinem Einfluss auf das Christentum*, 1894; Wobbermin, *Religionsgeschichtliche Studien zur Frage der Beeinflussung des Urchristentums durch das antike Mysterienwesen*, 1896; and for the organization of the early Church Harnack, *Mission und Ausbreitung des Christentums*, pp. 337 seq., and to the same writer's *Texte und Untersuchungen*, ii. 5 (Eng. tr. *Sources of the Apostolic Canons*, 1895).

(A. C. McG.; A. Hk.; W. A. P.; X.)

CHURCHILL, CHARLES (1731-1764), English poet and satirist, was born in Westminster, in Feb. 1731. His father, a clergyman, destined his son for the Church, and Charles was ordained in 1756. He was married at the age of 18, but his married life was unhappy and in 1761 he separated from his wife. He had lived a poverty-stricken life until that year, when he published, anonymously and without advertisement, the *Rosciad* at the price of a shilling. This brilliant but merciless satire described one by one the faults and eccentricities of the leading actors and actresses of the London stage, David Garrick almost alone escaping censure. It lay but a few days unnoticed in the bookshops; it was soon taken up with enthusiasm and the secret of its authorship publicly debated. It was attributed to Robert Lloyd, an amiable Welsh poet who, on Churchill's acknowledging the authorship, became his great friend. Churchill followed up the *Rosciad* with the *Apology*, in which his strictures were repeated and even Garrick was threatened. The actor sent through Lloyd an anxious and alarmed letter which flattered the poet by showing the fear which he already inspired. More, perhaps, even than his new-found power, Churchill enjoyed the wealth which his poems brought him. He paid his debts, made an allowance to his wife and started on a career of loose living and dandiacal dressing, which led, in 1763, after protests from his parishioners

and his bishop, to his being forced to resign his living. He defended in 1761 his method of life in a poem called *Night*, of which Smollett's *Critical Review* said in Dec. 1761, not unfairly, "This *Night*, like many others at this time of the year, is very cold, long, dark and dirty." With Sir Francis Dashwood and John Wilkes (*qq.v.*) he drank wine in the globe at the top of West Wycombe church, and indulged in even less seemly pranks; he may even have been one of the famous Medmenham monks.

He became, in 1762, along with Lloyd, a close ally of Wilkes and assistant editor of the *North Briton* throughout its career, assisting its furious political campaign by rhymed satires which were almost equally feared: *The Prophecy of Famine* (1763), an attack on Lord Bute and the Scots, an *Epistle to William Hogarth* (1763), a reply to Hogarth's attack on Temple and Pitt; *The Duellist* (1763), an attack on Samuel Martin, M.P., who had attempted to kill Wilkes, and *The Candidate* (1764), an exposure of "Jemmy Twitcher," Lord Sandwich, Wilkes' chief enemy. His other completed works are *The Ghost*, *The Conference*, *The Author* (1763), *The Farewell*, *Independence*, *The Times* and *Gotham* (1764), of which the last is perhaps the best. He died of a fever on a visit to Wilkes in exile at Boulogne on Nov. 4, 1764.

Churchill was elephantine in figure: he has drawn his own picture in *Independence*:—

Vast were his bones, his muscles twisted strong;
His face was short, but broader than 'twas long;
His features, though by nature they were large,
Contentment had contrived to overcharge,
And bury meaning, save that we might spy
Sense lowering in the penthouse of his eye;
His arms were two twin oaks; his legs so stout
That they might bear a Mansion House about;
Nor were they, look but at his body there,
Designed by fate a much less weight to bear.

Churchill excelled in invective and malicious portraiture, as of Warburton, the pedantic and ambitious bishop of Gloucester:—

Who was so proud, that should he meet
The Twelve Apostles in the street,
He'd turn his nose up at them all
And shove his Saviour from the wall.
(*The Duellist*.)

In his lifetime he was grossly overpraised and his death was lamented as a privation equal to the loss of Hogarth. Since then he has suffered an almost total eclipse. But he possesses great merits: his English is clear and vigorous, his wit and talent for invective are undoubted, and his poetic genius, of a Juvenalian character, much above the average. But it requires a great knowledge of 18th century politics and an equally great interest to appreciate his merits, and for that reason he is never again likely to be widely read.

See his *Collected Poems*, edited by W. Tooke with a biography and letters (1804), and re-edited by J. L. Hannay (1892), and the books cited under WILKES. (R. W. P.)

CHURCHILL, LORD RANDOLPH HENRY SPENCER (1849-1895), English statesman, third son of John, 7th duke of Marlborough, by Frances, daughter of the third marquess of Londonderry, was born at Blenheim palace, on Feb. 13, 1849. He was educated at Eton and at Merton college, Oxford. In 1874 he was elected to parliament in the Conservative interest for Woodstock.

In 1878 he forced himself into public notice as the exponent of a species of independent Conservatism. He directed a series of furious attacks against some of the occupants of the front Ministerial bench. Sclater-Booth (afterwards 1st Lord Basing), president of the Local Government Board, was a special object of attack, and denounced as the "crowning dishonour to Tory principles." In the new parliament of 1880, Churchill began to play a more notable rôle. With the assistance of Sir Henry Drummond Wolff, Sir John Gorst and occasionally of Arthur Balfour, and one or two others, he constituted himself at once the audacious opponent of the Liberal Administration and the unsparring critic of the Conservative front bench. The "fourth party," as it was nicknamed, was effective in awakening the

Opposition from the apathy which had fallen upon it after its defeat at the polls. Churchill roused the Conservatives and gave them a fighting issue, by putting himself at the head of the resistance to Charles Bradlaugh, the member for Northampton, who, though an avowed atheist or agnostic, was prepared to take the parliamentary oath. He continued to play a conspicuous part throughout the parliament of 1880-85, dealing his blows with almost equal vigour at Gladstone and at the Conservative front bench, some of whose members, and particularly Sir Richard Cross and W. H. Smith, he assailed with extreme virulence.

From the beginning of the Egyptian imbroglio Lord Randolph emphatically opposed almost every step taken by the Government. He declared that the suppression of Arabi Pasha's rebellion was an error, and the restoration of the khedive's authority a crime. He was equally severe on the domestic policy of the Administration, and was particularly bitter in his criticism of the Kilmainham Treaty and the *rapprochement* between the Gladstonians and the Parnellites. It is true that for some time before the fall of the Liberals in 1885 he had considerably modified his attitude towards the Irish question, and was himself cultivating friendly relations with the Home Rule members, and even obtained from them the assistance of the Irish vote in the English constituencies in the general election. By this time he had definitely formulated the policy of progressive Conservatism which was known as "Tory democracy." He declared that the Conservatives ought to adopt, rather than oppose, reforms of a popular character, and to challenge the claims of the Liberals to pose as the champions of the masses. His views were to a large extent accepted by the official Conservative leaders in the treatment of the Gladstonian Franchise bill of 1884. Lord Randolph insisted that the principle of the bill should be accepted by the Opposition, and that resistance should be focussed upon the refusal of the Government to combine with it a scheme of redistribution. The prominent, and on the whole judicious and successful, part he played in the debates on these questions, still further increased his influence with the rank and file of the Conservatives in the constituencies. At the same time he was actively spreading the gospel of democratic Toryism in a series of platform campaigns. In 1883 and 1884 he invaded the Radical stronghold of Birmingham itself, and in the latter year took part in a Conservative garden party at Aston Manor, at which his opponents paid him the compliment of raising a serious riot. He gave constant attention to the party organization, and was an active promoter and first member of the Primrose League, which owed its origin to the happy inspiration of one of his own "fourth party" colleagues.

In 1884 the struggle between stationary and progressive Toryism ended in favour of the latter. At the conference of the Central Union of Conservative Associations, Lord Randolph was nominated chairman, notwithstanding the strenuous opposition of the parliamentary leaders of the party. The split was averted by Lord Randolph's voluntary resignation; but the episode had confirmed his title to a leading place in the Tory ranks. It was further strengthened by the prominent part he played in the events immediately preceding the fall of the Liberal Government in 1885; and when Childers's budget resolutions were defeated by the Conservatives, aided by about half the Parnellites, Lord Randolph Churchill's admirers were justified in proclaiming him to have been the "organizer of victory." Owing to Lord Randolph's refusal to serve under Sir S. Northcote's leadership, Lord Salisbury had great difficulty in forming a cabinet in June 1885. Finally a way out of the *impasse* was found by elevating Northcote to the peerage (as earl of Iddesleigh) and giving the leadership in the House of Commons to Sir M. Hicks Beach. Lord Randolph was given the India Office, where "the India Council would be a check on him." (*Letters of Queen Victoria*, second series, vol. iii., p. 663.) During the few months of his tenure of this great post the young free-lance of Tory democracy attended to his departmental duties and mastered the complicated questions of Indian administration. In the autumn election of 1885 he contested Central Birmingham against Bright, and though defeated here, was at the same time returned by a very large ma-

jority for South Paddington. In the Home Rule controversy, both in and out of parliament, Lord Randolph again bore a conspicuous part. He was now the recognized Conservative champion in the lower chamber, and when the second Salisbury Administration was formed after the general election of 1886 he became chancellor of the exchequer and leader of the House of Commons. His management of the House was on the whole successful, and was marked by tact, discretion and temper. But he had never really reconciled himself with some of his colleagues, and there was a good deal of friction in his relations with them, which ended with his sudden resignation on Dec. 20, 1886. Various motives influenced him in taking this step; but the only ostensible cause was that put forward in his letter to Lord Salisbury, read in the House of Commons on Jan. 27, in which he stated that his resignation was due to his inability, as chancellor of the exchequer, to concur in the demands made on the Treasury by the ministers at the head of the naval and military establishments and that a better foreign policy might obviate the necessity for such demands. Although he himself refrained from offering any public explanation of his conduct, nor in any way sought to bring about a reconciliation with Salisbury, Lord Randolph Churchill's prestige was so great that a reconstruction of the cabinet proved a task of great difficulty. At length Goschen was induced to accept the chancellorship, and Churchill disappeared from any effective part in the leadership of the Conservative Party.

He continued, for some years longer, to give a general, though decidedly independent, support to the Unionist Administration. On the Irish question he was a very candid critic of Balfour's measures, and one of his later speeches, which recalled the acrimonious violence of his earlier period, was that which he delivered in 1890 on the report of the Parnell commission. He also fulfilled the promise made on his resignation by occasionally advocating the principles of economy and retrenchment in the debates on the naval and military estimates. In April 1889, on the death of Bright, he was asked to stand for the vacant seat in Birmingham, and the result was a rather angry controversy with Chamberlain, terminating in the so-called "Birmingham compact" for the division of representation of the Midland capital between Liberal Unionists and Conservatives. But his health was already precarious, and he bestowed much attention on society, travel and sport. He was an ardent supporter of the turf, and in 1889 he won the Oaks with a mare named the Abbess de Jouarre. In 1891 he went to South Africa, in search both of health and relaxation. He travelled for some months through Cape Colony, the Transvaal and Rhodesia, and recorded his impressions in a book entitled *Men, Mines and Animals in South Africa*.

In the general election of 1892 he once more flung himself, with his old vigour, into the strife of parties. His seat at South Paddington was uncontested, and when parliament met he returned to the Opposition front bench to take a leading part in debate, attacking Gladstone's second Home Rule bill with especial energy. He died in London on Jan. 24, 1895.

Lord Randolph Churchill married, in Jan. 1874, Jennie, daughter of Leonard Jerome of New York, U.S.A., by whom he had two sons. In 1900 Lady Randolph Churchill married G. Cornwallis-West.

An authoritative biography of Lord Randolph, by his son Winston appeared in 1906; and a brief and intimate appreciation by Lord Rosebery, inspired by this biography, was published a few months later. Lord Randolph's earlier speeches were edited, with an introduction and notes, by Louis Jennings (2 vols., 1889). See also H. W. Lucy, *Diary of Two Parliaments* (1892); and Mrs. Cornwallis-West, *The Reminiscences of Lady Randolph Churchill*, (i.e., of the author) (1908); *The Letters of Queen Victoria*, second series, 3 vols. (1926-28).

CHURCHILL, WINSTON (1871-), American writer, was born in St. Louis, Mo., Nov. 10 1871. He graduated from the United States naval academy in 1894, soon devoting himself to writing. His first novel, *The Celebrity*, appeared in 1898. His next *Richard Carvel* (1899), a novel of Maryland in the time of the Revolution, had a sale of nearly 1,000,000 copies. Then followed *The Crisis* (1901), the heroine of which is a de-

scendant of his former hero, Richard Carvel; and *The Crossing* (1904). His other novels include: *Coniston* (1906); *Mr. Crewe's Career* (1908); *A Modern Chronicle* (1910); *The Inside of the Cup* (1913); and *The Dwelling Place of Light* (1917). Although his later work has consisted chiefly of problem novels, his romantic tales of America's past have most endeared him to his public. He has taken an active part in State politics. From 1903 to 1905 he was a member of the New Hampshire legislature, and in 1913 he was a candidate for the governorship as a Progressive.

CHURCHILL, WINSTON LEONARD SPENCER (1874-), British statesman, elder son of Lord Randolph Churchill and Jennie, daughter of Leonard Jerome, of New York, U.S.A., was born on Nov. 30, 1874. He was educated at Harrow and Sandhurst. Entering the army in 1895, his principal war service was with the Malakand field force (1897) and the Tirah expeditionary force (1898); these campaigns gave him material for two brilliant books, *The Story of the Malakand Field Force* (1898), and *The River War* (1899). During the South African War (1899-1902) he was correspondent for *The Morning Post* and wrote an account of his experiences as *London to Ladysmith via Pretoria* (1900). He was taken prisoner by the Boers, but escaped.

Churchill was elected Conservative M.P. for Oldham in 1900, and immediately made his mark in a House which expected great things from his father's son. He excelled in the set speech elaborately prepared on the classic models, but was not at first a ready speaker. Lord Balfour once said of him that he carried "heavy but not very mobile guns," and it was only later that he became a master in the cut and thrust of debate. He had a filial reverence for the political memory of his father and his *Life of Lord Randolph Churchill* (1906) is one of the most interesting political biographies in the language.

In his first session Churchill opposed the Brodrick scheme of army reorganization mainly on financial grounds, and when Joseph Chamberlain began his tariff reform campaign he threw himself into the ranks of the Free Traders with uncompromising vehemence. He then joined the Liberal party, and fought a severely contested election at North-West Manchester at the general election of 1906. He was under-secretary for the colonies in Sir Henry Campbell-Bannerman's Govt. (1905-08), and the spokesman of his department in the House of Commons. Even at the time of the South African War he had held liberal views about the treatment of the Dutch. As under-secretary, he expounded Sir Henry Campbell-Bannerman's policy of self-government for the Transvaal and Orange River colonies, leading up to the federation of South Africa, with such skill and authority that his position in the House of Commons was much advanced. Place was made for him (1908) in the cabinet as president of the Board of Trade. There, and later at the Home Office, he showed a keen interest in social legislation. He carried a Trade Boards Act establishing a minimum wage in certain sweated industries, an act setting up labour exchanges, and a Shops Act. It may fairly be said that these three measures reorganized those trades which were then unorganized or feebly organized; the Trade Boards Act, developed and expanded, removed a dark blot on English industrial life. The Old Age Pensions Act and other social measures, for which he was not immediately responsible, found in him a brilliant advocate.

By 1909 Churchill had become a great power in the Liberal Party. His platform oratory had a vivacity, a boldness and an epigrammatic quality that stirred popular gatherings. Into the conflict that followed the rejection of the Lloyd George budget by the House of Lords, he threw himself with characteristic impetuosity. As president of the Budget League he was a driving force in the campaign against the Lords' veto on finance. On the question of Irish Home Rule he had also made a definite advance. During the Ulster agitation in 1912 against the Home Rule Bill Churchill was announced to speak in favour of the Bill at the Ulster hall, Belfast. On Jan. 16, the Ulster Unionist Council declared that he should not be allowed to speak there. He was not the man to be intimidated, and the meeting took place on Feb. 8 on a Nationalist club football ground. At that

meeting he defined his position in the words "that any plan for Home Rule put forward would be an integral part of parliamentary devolution, and would not be inconsistent with the design of the ultimate federation of the empire."

But events on a larger stage were shaping themselves to give a new direction to Churchill's career. In July 1911 Great Britain came into dangerous clash with Germany over what was known as the Agadir incident (*q.v.*). A conflict was avoided, but the German menace now loomed as a reality. Churchill was transferred from the Home Office to the Admiralty, with explicit injunctions laid upon him by Asquith, to "put the fleet into a state of instant and constant readiness for war in case we were attacked by Germany"—a disclosure made at Dundee by Churchill in June, 1915. The reason for Churchill's appointment to the Admiralty was that a serious disagreement had arisen between the War Office and the Admiralty concerning the strategy to be adopted in the event of war, and Haldane had told Asquith that he would resign from the War Office unless the Admiralty worked in accordance with the War Office plans and a naval war staff was created. To that the existing admiralty board and McKenna were opposed and it was therefore one of Churchill's first duties to make a new board. "He is knocking over the admirals like ninepins," it was said at the time. The formation of a naval war staff was less easy and some years were necessary before it could do its work adequately. He was, at this time, in constant communication, though not always in agreement, with Lord Fisher; but he did not recall him to the Admiralty. In addition to the creation of a naval war office Churchill carried out many major reforms in the navy and its administration. His tenure of office saw the introduction of the 15 in. gun, the development of the light cruiser type and the creation of a famous division of fast battleships ("Queen Elizabeth" type). In the personnel of the navy changes were effected; Sir John Jellicoe was his second sea lord (1912-14), and at the outbreak of war was placed by a strong decision of the Admiralty in command of the Grand Fleet, while Sir David Beatty was in close touch with Churchill as his naval secretary (1912), and was given the command of the 1st Battle Cruiser Squadron in the same year.

Gradually a rift appeared between Churchill and Lloyd George, for Churchill was convinced that war was coming, whereas Lloyd George, despite his speech at the Mansion House on the Agadir crisis, was not. When the World War came it found the fleet, owing to the coincidence of the manoeuvres, on a war footing. Churchill had done important work in preparing the fleet for war, but the operations of the navy in the first few months of the struggle suffered from the lack of clear and consistent direction which a naval war staff would have supplied. Nevertheless, at the outset of the war troops were safely transported, the outer oceans cleared and the German High Seas fleet contained. Churchill presently found himself the leader of a minority and opposition school of war strategy of which the Antwerp expedition and the Dardanelles enterprise were the main projects. In both cases the strategic conception was not only sound but brilliant, but the forces required for their success were not forthcoming, and Churchill's own impatience contributed to their failure. Lord Fisher in particular, who had been recalled to the Admiralty (Oct. 1914), disliked the Dardanelles enterprise, and his resignation in May, 1915, was one of the causes of the downfall of the Liberal Government. Churchill suffered a great blow. He was succeeded at the Admiralty by Balfour. For a few months he remained in office as chancellor of the duchy of Lancaster, but resigned on Nov. 13 on the ground of his non-inclusion in the new war committee of the cabinet.

This step was followed by a lengthy and vigorous speech of personal explanation and vindication in the House of Commons, which was a performance of great power. Denying an improper usurpation of authority while at the Admiralty, Churchill described the Dardanelles adventure as a legitimate war gamble. He blamed Lord Fisher for not speaking out in the War Council if he did not approve the operation, declaring at the same time that he had not received from the first sea lord either the clear guidance before the event or the firm support after that he was

entitled to expect. After this Churchill went on active service in France, where he commanded the 6th Royal Scots Fusiliers.

Lloyd George recalled him to high office. He was again on the Treasury bench in 1917 as minister of munitions and then as secretary for war and air minister (1918-21). He supervised the return of the army to a voluntary basis. Apart from his conspicuous part in the Irish settlement he began to be less in agreement with the premier. Lloyd George disliked his Russian policy and the expensive campaigns conducted against the Bolsheviks under his inspiration. The outward sign of this estrangement was the appointment of Sir Robert Horne instead of Churchill to the chancellorship of the exchequer left vacant by the retirement of Bonar Law. This was one of the temporary disappointments of Churchill's career. Churchill went to the Colonial Office (1921-22). Less in favour with Lloyd George and still unpopular with the Conservatives, he seemed to be drifting into extreme insecurity and isolation.

The downfall of the Coalition which seemed likely to complete his political ruin was in fact his salvation. After his rejection by Dundee (1922), Churchill had a period of retirement, during which he devoted himself to writing, painting and other pursuits. He now wrote the first volume of *The World Crisis 1916-18* (published with the remaining volume in 1927), in which he expressed the opinion that the great allied offensives of 1915, 1916 and 1917 were wrongly conceived and costly operations and maintained his "Eastern front" thesis.

In March 1924 Churchill challenged attention by presenting himself as an independent anti-Socialist candidate at a by-election in the Westminster Abbey division. Backed by powerful Conservative support against the official nominee, he was only defeated by 40 votes on a very heavy poll. The idea of a strong Centre Party, combining Conservatives and Liberals against Socialism, had appealed strongly to him, but in the following September he was adopted as Conservative candidate for the Epping division. Elected to the House of Commons he obtained at last the post his father had held, being called to be chancellor of the exchequer in the second Baldwin administration (Nov. 1924). On April 28, 1925, he presented his first budget, his proposals including a return to the gold standard, a new duty on silks, an extension of imperial preference, a reimposition of the McKenna duties, provision for pensions for widows and a reduction of the tax on earned incomes. His second budget (1926) was less striking; the salient feature was the extension of the McKenna duties to cover commercial motor vehicles, and the reimposition for ten years of those key industry duties due to expire. In the budget of 1927 he marked time, but in 1928 he put forward historic proposals for the readjustment of rating; industry in distressed districts was to be relieved of part of its heavy burden from the proceeds of new taxes imposed. The years of Churchill's chancellorship saw the progressive settlement of outstanding war debts questions and other important readjustments in national finance.

CHURCHILL (Missinnippi or English), the name of a river of the province of Saskatchewan and district of Keewatin, Canada. It rises in La Loche (or Methy) lake, a small lake in 56° 30' N. and 109° 30' W., at an altitude of 1,577 ft. above the sea, and flows east-north-east to Hudson's Bay, passing through a number of lake expansions. Its principal tributaries are the Beaver (350 m. long), Sandy and Reindeer rivers. Between Frog and Methy portages (480 m.) it formed part of the old *voyageur* route to the Peace, Athabasca and Mackenzie. It is still navigated by canoes, but has many rapids. The Churchill is 925 m. long. Ft. Churchill, at its mouth, is the best harbour in the southern portion of Hudson's Bay. It is to be the terminus of the Hudson's Bay railway, and not Port Nelson as originally planned. The river has enormous undeveloped water powers.

CHURCHING OF WOMEN, the Christian ceremony of thanksgiving on the part of mothers shortly after the birth of their children. It no doubt originated in the Mosaic regulation as to purification (Lev. xii.; cf. Lk. ii. 22). In ancient times the ceremony was usual but not obligatory in England. In the Greek and Roman Catholic Churches to-day it is imperative. No ancient

form of service exists, and that which figures in the English Prayer Book of to-day dates only from the middle ages. In the Prayer Book of 1549 the rite was called the Purification of Women; but this was altered in 1552 to the present form, Thanksgiving of Women after Childbirth. (See Hooker, *Eccl. Pol.* V. lxxiv.) Custom differs, but the usual date of churching was the fortieth day after confinement, in accordance with the Biblical date of the presentation of the Virgin Mary and the Child Jesus at the Temple. It was formerly regarded as unlucky for a woman to leave her house to go out at all after confinement till she went to be churchied. It was not unusual for the churching service to be said in private houses. In some parishes there was a special pew known as "the churching seat." The words in the rubric requiring the woman to come "decently [*i.e.* suitably] apparelled" refer probably to the custom of wearing a veil upon the head.

The "convenient place," which, according to the rubric, the woman must occupy, was in pre-Reformation times the church-door. In the first Prayer Book of Edward VI. (1549), she was to be "nigh unto the quire door." In the second Prayer Book (1552), she was to be "nigh unto the place where the Table standeth." Bishop Wren's orders for the diocese of Norwich in 1636 are "That women to be churchied come and kneel at a side near the Communion Table without the rail, being veiled according to custom, and not covered with a hat." At her churching a woman was expected to make some offering to the church; the Prayer Book of 1549 orders that she shall offer the chrysom or robe used in the baptism; when, however, the use of the chrysom was discontinued, the reference to "accustomed offerings" was retained.

CHURCH OF THE BRETHREN: see GERMAN BAPTIST BRETHREN.

CHURCH RATE, the name of a tax formerly levied in each parish in England and Ireland for the benefit of the parish church. Out of this rate were defrayed the expenses of carrying on divine service, repairing the fabric of the church, and paying the salaries of the officials connected with it. The church rate was made by the churchwardens, together with the parishioners duly assembled after proper notice in the vestry or the church, and was a personal charge imposed on the occupier of land or of a house in the parish. Though it was compulsory, much difficulty was found in effectually applying the compulsion. This was especially so in the case of Nonconformists, who had conscientious objections to supporting the Established Church; and in Ireland, where the population was preponderatingly Roman Catholic, the grievance was specially felt and resented. The agitation against church rates led in 1868 to the passing of the Compulsory Church Rate Abolition Act. By this Act church rates are no longer compulsory on the person rated, but are merely voluntary, and those who are not willing to pay them are excluded from inquiring into, objecting to, or voting in respect of their expenditure (s. 8).

CHURCH STRETTON, urban district, Shropshire, England, situated on a low watershed in a narrow longitudinal valley between the Longmynd and the Caradoc ranges. (Pop., 1931, 1,705.) It takes its name from the Roman road joining Viroconium and Caerleon, on which it lies. The Great Western railway from Shrewsbury to Ludlow and the main road parallel to it make use of this gap, where the railway reaches a height of 600 feet. As a market town Church Stretton serves the hilly country between Wenlock Edge and Longmynd, but the area is limited by hill barriers and much trade drifts to Shrewsbury on the north and Craven Arms and Ludlow on the south. The hill ponies of the Longmynd are sold at an annual autumn fair. The neighbourhood has numerous prehistoric camps and barrows, while a remarkable ridgeway or "Portway" runs along the summit of the Longmynd.

CHURCHWARDEN, in England, the guardian or keeper of a church, and representative of the body of the parish. The office dates from the 14th century, when the responsibility of providing for the repairs of the nave, and of furnishing the utensils for divine service, was imposed on the parishioners. Resident lay householders of a parish are those primarily eligible as churchwardens, but non-resident householders who are habitually occu-

piers are also eligible, while there are a few classes of persons who are either ineligible or exempted. The appointment of churchwardens is regulated by the 89th canon, which requires that the churchwardens shall be chosen by the joint consent of the ministers and parishioners, if it may be; but if they cannot agree upon such a choice, then the minister is to choose one, and the parishioners another. If, however, there is any special custom of the place, the custom prevails, and the most common custom is for the minister to appoint one, and the parishioners another, and this has been established by English statute, in the case of new parishes, by the Church Building and New Parishes Acts 1818-84. There are other special customs recognized in various localities, *e.g.*, in some of the larger parishes in the north of England a churchwarden is chosen for each township of the parish; in the old ecclesiastical parishes of London both churchwardens are chosen by the parishioners; in some cases they are appointed by the select vestry, or by the lord of the manor, and in a few exceptional cases are chosen by the outgoing churchwardens. Each churchwarden after election subscribes before the ordinary a declaration that he will execute his office faithfully.

The duties of churchwardens comprise the provision of necessities for divine service; the keeping of order during the divine service and the giving of offenders into custody; the assignment of seats to parishioners; and the presentment of offences against ecclesiastical law: but by the Parochial Church Councils (Powers) Measure, 1921, No. 1 made under the Church of England Assembly (Powers) Act, 1919, c. 76, all powers, duties and liabilities of the churchwardens, relating to (a) the financial affairs of the church; (b) the maintenance and insurance of the fabric, goods and ornaments; (c) the maintenance of the churchyard (even when closed) were transferred to the new parochial church councils. The property in the movable goods and ornaments remains in the churchwardens.

In the Protestant Episcopal Church in the United States churchwardens discharge much the same duties as those performed by the English officials; their duties, however, are regulated by canons of the diocese, not by canons general. In the United States, too, the usual practice is for the parishes to elect both the churchwardens.

See J. H. Blunt, *Book of Church Law* (7th ed., 1894); C. G. Prideaux, *Churchwarden's Guide* (16th ed., 1895); J. Steer, *Parish Law* (6th ed., 1899).

CHURCHYARD, THOMAS (c. 1520-1604), English author, was born at Shrewsbury. He served in the household of Henry Howard, earl of Surrey, and in 1541 became a soldier of fortune. During the next 30 years he fought in almost every campaign in Ireland, Scotland and the Low Countries, now in the service of the Emperor Charles V., now in the English service, at last under the Prince of Orange. His last campaign was the defence of Zutphen in 1572.

Churchyard was employed to devise a pageant for the queen's reception at Bristol in 1574, and again at Norwich in 1578. He had published in 1575 *The firste parte of Churchyardes Chippes*, the modest title which he gives to his works. No second part appeared, but there was a much enlarged edition in 1578. A passage in *Churchyardes Choise* (1579) gave offence to Elizabeth, and the author fled to Scotland, where he remained for three years. He was only restored to favour about 1584, and in 1593 he received a small pension from the queen. The affectionate esteem with which he was regarded by the younger Elizabethan writers is expressed by Thomas Nashe, who says (*Four Letters Confuted*) that Churchyard's aged muse might well be "grandmother to our grandiloquentest poets at this present."

His writings, with the exception of his contributions to the *Mirror for Magistrates*, are chiefly autobiographical in character, or deal with the wars in which he had a share. They are very rare, and have never been completely reprinted. Churchyard lived right through Elizabeth's reign, and was buried in St. Margaret's Church, Westminster, on April 4, 1604.

BIBLIOGRAPHY.—The extant works of Churchyard, exclusive of commendatory and occasional verses, include:—*A lamentable and pittifull Description of the wofull warres in Flanders* (1578); *A gene-*

eral rehearsall of warres, called *Churchyard's Choise* (1579), really a completion of the *Chippes*, and containing, like it, a number of detached pieces; *A light Bondel of livelie Discourses, called Churchyard's Charge* (1580); *The Worthines of Wales* (1587), a valuable antiquarian work in prose and verse, anticipating Michael Drayton; *Churchyard's Challenge* (1593); *A Muscicall Consort of Heavenly harmonie . . . called Churchyard's Charitie* (1595); *A True Discourse Historiell, of the succeeding Governors in the Neiterlands* (1602).

The chief authority for Churchyard's biography is his own "Tragical Discourse of the unhappy man's life" (*Churchyard's Chippes*). George Chalmers published (1817) a selection from his works relating to Scotland, for which he wrote a useful life. See also an edition of the *Chippes* (ed. J. P. Collier, 1870), of the *Worthines of Wales* (Spenser Soc., 1876) and a notice of Churchyard by H. W. Adnitt (*Transactions of the Shropshire Archaeological and Nat. Hist. Soc.*, reprinted separately 1884).

CHURCHYARD, a piece of consecrated ground attached to a parochial church, and used as a burial place. It is distinguished from a cemetery (*q.v.*), which is also a place of burial, but is separate and apart from any parochial church. (See **BURIAL**.)

CHURL. In Old English law the word *ceorl* denoted the ordinary free man, who formed the basis of Anglo-Saxon society. In the course of time he lost much of his original independence, and after the Norman Conquest became included within the great class of villeins (see **VILLEINAGE**) who were regarded in law as personally unfree. It is largely owing to this depression that the word "churl" came to bear a derogatory sense. Nevertheless, even in Anglo-Norman law the *ceorl* had not wholly sunk into a servile position; he retained the wergild of a free man until the whole system of wergilds became obsolete, and he was long subject to the duty of attending public courts such as that of the Hundred (*q.v.*). His depression was due essentially to economic causes; men of his class suffered heavily in the wars of the 10th and 11th centuries and the lawyers of a later time who regarded their descendants as legally dependent upon their lords were only recognizing accomplished facts.

CHURN: see **DAIRY MACHINERY**.

CHURRIGUERESQUE, in architecture, the late, luxuriant, Spanish baroque style, so called from its most famous architect, Don José Churriguera (d. 1725). See **ARCHITECTURE**; **RENAISSANCE ARCHITECTURE**.

CHURUBUSCO, a village of Mexico on the river of the same name, about six miles south of the capital. It contains a massive stone convent. It was here that Major General Winfield Scott in his brilliant southern campaign of the war between Mexico and the United States (1846-48) fought the battle of that name as an aftermath of the action at Contreras the same day (August 20, 1847). Brigadier General Worth, who had been acting as rear guard at San Agustín, moved forward toward San Antonio to find, after trying a turning movement, that, on account of the victory at Contreras, the strong fortifications before him had been evacuated by General Santa Anna's Mexicans. Worth pressed on to meet stout and unexpected resistance at the bastioned bridgehead of Churubusco. Scott, taking charge of Pillow's and Twiggs' troops, a part of whom he sent to reinforce Worth, decided upon a turning movement. Sending Pierce and Shields over a road around Santa Anna's right flank, he ordered them to strike the Mexican general in rear. Though the untrained militia making the detour did not at first acquit themselves well, Worth stubbornly pressed in front and, after severe charging in which his troops succeeded in turning Santa Anna's left flank, was able to take the bridgehead and the well fortified convent beyond. The pursuit continued for over two miles. In addition to the guns and ammunition taken, the Mexican losses probably mounted to 10,000. The Americans lost about 950.

Ganoe, *The History of the United States Army* (1924); Original Correspondence and Reports in Old Files Section, Adjutant General's Office, Washington, D.C. (W. A. G.)

CHUSAN, an island archipelago off the Chinese coast. It represents the submerged terminus of the Tayu-ling, the dominating range of Chekiang, which is linked on south-westwards with the high ranges along the Fukien-Kiangsi border. The outermost islands of the archipelago lie across the entrance to Hangchow

bay. Their shores are becoming choked with silt from the Yangtze estuary, which opens out just to the north of them, in perhaps the same way as at an earlier period the hills along the E. side of the Tai-hu became linked together by stretches of alluvium. If this interpretation is correct, the shallow Hangchow bay may in time become a second Tai-hu. By reason of its character as a rocky island and of its proximity to the Yangtze estuary, Chusan island, the largest of the archipelago, was during the Ming Dynasty (1368-1644) an entrepôt for trade with Japan. Until the modern development of Japan, Japanese relations with China were naturally most intimate in the neighbourhood of the Yangtze estuary. The Japanese use of Chusan at that time is somewhat comparable to the British use of Hongkong at a later period.

CHUTE, a channel or trough, artificial or natural, down which objects, such as timber, coal or grain may slide, identical in meaning and pronunciation with "shoot." A channel cut in a dam on a river for the passage of floating timber, and in Louisiana and on the Mississippi a channel at the side of a river or narrow way between an island and the shore. The "water-chute," a steep wooden slope terminating in a shallow lake down which run flat-bottomed boats, is a Canadian pastime, which has been popular in London and elsewhere.

CHUTNEY, a sweet pickle or relish prepared from sweet fruits such as mangoes, raisins, etc., with acid flavouring from tamarinds, lemons, limes and sour herbs, and with a hot seasoning of chillies, cayenne pepper and spices. The word is an anglicized form of the Hindustani *chatni*.

CHUVASHES, a tribe found in east Central Russia, in the government of Kazan and throughout the governments of Simbirsk, Samara, Saratov, Orenburg and Perm. Some think they are the descendants of the ancient Bulgars. In general, like the Finns they are round-headed, flat-featured and light-eyed, but have been affected by Tatar elements. They are nominally Christians, but cling to many Shamanistic practices. Their language belongs to the Turkish group, but has been strongly influenced by the Finno-Ugrian idioms spoken round it.

See Schott, *De Lingua Tschuwashorum* (Berlin, 1841).

CHUVASHIA, an A.S.S.R. in the Russian Socialist Federal Soviet Republic, created as an autonomous area by decree in June, 1920, and declared an autonomous republic in April, 1925. Area, 18,413 sq. km. Its boundaries are west, Nizhegorod; south, Ulianovsk; east, Tatar A.S.S.R.; north, Marii autonomous area. East of the Nizhegorod province, from the junction of the Sura river with the Volga river, begins the forest area in which many Finno-Turkish tribes maintained their linguistic and racial individuality against the advancing waves of Slav colonization. Of these tribes the Chuvash occupy the area between the right bank of the Sura and Volga and are thus nearest to Moscow. The population (1926), 894,475, includes Chuvash 80%, Great Russians 18%, Tatars and Marii (Cheremiss). The urban population is 42,035, of whom 85% are Great Russians. In the south and west the republic is forested, but towards the north and east the forest only remains in patches. Deforestation is progressing rapidly; 70% of the timber annually cut is not replaced. From ancient times lumbering, sawmilling and the making of wooden articles, *e.g.*, furniture, oak rivets, barrels, wagons, shovels, have been the chief occupation of the Chuvash, and 94% of the koustar (peasant) industries are of this nature. The Alatyr district is noted for its koustar furniture industry. Agriculture is poorly developed, owing to poor soils and climatic conditions and to the primitive methods adopted. The soils are podzolized or degraded soils and lichen black soils (see **RUSSIA, Soils**). The climate is severe; snow lies for the five months from October to April, and the rivers are frozen. There are fierce storms in winter and spring and in June and July thunderstorms are frequent. The prevailing winds are south-west and in the hot summer they bring sand from the steppe, so that the crops are covered with dust. In 1924-25 the extent of ploughed land was 43.3%, and of forest 35.1%. Oats and rye occupy 85% of the sown area and wheat only 2.2%; other small crops are spelt, buckwheat, barley, millet, peas, lentils, flax, hemp and potatoes, but there was a serious deterioration in agriculture during the 1914-21 period. Even the 1925 harvest

was 40% less than in pre-war times. The Chuvash suffered very severely during the Civil War and in the 1920–21 famine: the population fell from 745,000 in 1914 to 201,000 in 1920, and the effects of the hardships of that terrible time are still evident in the survivors, and in the lack of horses, working cattle and farm implements.

The chief agricultural exports are oats by waterway to Lenin-grad and by rail to Moscow, and eggs and poultry. Small quantities of honey, apples and hops are also exported. Though Chuvash horses, cattle, sheep and pigs are underfed and undersized, cattle, meat, wool and hides are exported. The standard of living is low and the imports are mainly salt, kerosene and iron goods, but in spite of the few cultural needs of the people there are 65 bazaar centres and four annual fairs. Cheboksari, on the Volga river, the administrative centre, is a river port with an electric plant and a radio station, and its fair is the most important. It also has sawmills, printing works, dried fruit, starch and syrup industries. The only other industrial concern is the Yadrinsk oil-pressing factory, which employed 2,000 men in pre-war times (1,000 in 1925). Distilling, leather work, flour milling, hemp, fulling and metal industries of a koustar and semi-koustar type are carried on, and there are six steam flour mills. The Volga and Sura rivers provide navigable waterways in the summer. The Kazan to Kanash railway, linking through Arzamas in the Nizhegorod province, is the shortest route to Moscow. Kanash (formerly Shikhra) is an important timber and grain centre and from it a branch line goes south west through Alatyr, also a grain and timber centre, with an elevator. Plans for the development of the republic include the linking of Kanash to Cheboksari, and the development of a peat industry.

The percentage of illiteracy is high; in 1920 only 23.2% of the population could read and write. The Soviet Government has inaugurated a policy of instruction in the vernacular, which belongs to the Tatar or Turkish group, but has many Finno-Ugrian idioms. A Chuvash daily paper is issued and in Cheboksari a Chuvash theatre and museum have been established; literacy is greatly increasing. The Chuvash are of Finno-Tatar origin, round-headed, flat-featured and light-eyed; they are thought by some to be the descendants of the ancient Bulgars. Their preferences at present are for agriculture of a somewhat primitive type, and for small peasant industries, rather than for industrial occupations. The rapid deforestation of the area, its proximity to Moscow and the central productive region, combined with the effects of improved communications, will inevitably alter their outlook.

CHWANA, a collective name applied to a number of Bantu-speaking tribes inhabiting the interior plain of South Africa north of the Orange river. The most important are the baMangwato, baKwena, baHurutshe, baNgwaketse, baTlapin and baRolong. They all live by pastoralism combined with agriculture. They are organized socially into large totemic groups which are not exogamous. Marriage is legalized by the payment of a bride-price; and in some of the tribes ortho-cousin marriage is permitted. Their religion is mainly ancestor-worship, with strong traces of monotheism associated with a supreme being known as *Modimo*. Formerly there also appears to have been a certain degree of totemic ritual.

See J. T. Brown, *Among the Bantu Nomads* (1926).

CHWANBEN: see **KHAM**.

CIALDINI, ENRICO (1811–1892), Italian soldier, politician and diplomatist, was born in Castelvetro, Modena. In 1831 he took part in the insurrection at Modena, fleeing afterwards to Paris, whence he proceeded to Spain to fight against the Carlists. Returning to Italy in 1848, he commanded a regiment at the battle of Novara. In 1859 he organized the Alpine brigade, fought at Palestro at the head of the 4th Division, and in the following year invaded the marches, won the battle of Castelfidardo, took Ancona, and subsequently directed the siege of Gaeta. In 1861 his intervention envenomed the Cavour-Garibaldi dispute. Placed in command of the troops sent to oppose the Garibaldian expedition of 1862, he defeated Garibaldi at Aspromonte. Between 1862–66 he held the position of lieutenant-royal at Naples, and in 1864 was created senator. On the outbreak of the war of 1866 he resumed command of an army corps, but dissensions between

him and La Marmora contributed to the defeat of Custoza. In 1867 he attempted unsuccessfully to form a cabinet sufficiently strong to prevent the threatened Garibaldian incursion into the papal States, and two years later failed in a similar attempt, through disagreement with Lanza concerning the army estimates. On Aug. 3, 1870, he pleaded in favour of Italian intervention in aid of France, a circumstance which enhanced his influence when in July 1876 he replaced Nigra as ambassador to the French republic. This position he held until 1882, when he resigned on account of the publication by Mancini of a dispatch in which he had complained of arrogant treatment by M. Waddington. He died at Leghorn, on Sept. 8, 1892.

See G. Marcotti, *Il Generale Enrico Cialdini* (Florence, 1892); N. Nisco, *Il Generale Cialdini e i suoi tempi* (Naples, 1893); Prince Adam Wiszniewski, *Le Général Cialdini*, etc. (1913).

CIAMICIAN, GIACOMO LUIGI (1857–1922), Italian chemist, was born at Trieste on Aug. 22, 1857; his father was of American origin. He was educated at Trieste and Vienna but took his doctorate in 1880 at the University of Giessen. He became assistant and later reader in the institute of general chemistry of the University of Rome. In 1887 he was appointed professor of general chemistry in the University of Padua and in 1889 accepted the chair of chemistry at the University of Bologna, retaining this appointment until his death on Jan. 2, 1922.

Ciamician was a great teacher as well as a great investigator in chemistry, his researches in this science were very wide, the most important being in organic chemistry. He stressed its application to biological chemistry rather than the discovery of new compounds. An investigation on the compounds in animal tar led him, early in his career, to the important researches on pyrrole. Dr. Silber of Rome and others assisted Ciamician with some of this work and about 80 papers were published between 1880 and 1900. A monograph *Il Pirrolo e i suoi Derivati* (1888) gained the royal prize of the Accademia dei Lincei; the work is summarized in a paper "on the development of the chemistry of pyrrole in the last quarter of a century" read to the Deutsche Chemische Gesellschaft in 1904.

Ciamician was also a pioneer in the chemistry of vegetable products, at first he worked on organic compounds of vegetable origin and published a number of papers on this subject; the essential oil of celery was the subject of an important investigation. Later he became interested in the chemistry of the substances in the living plant and their biological significance; he inoculated plants and seeds with alkaloids and with their constituents. The work was summarized in an address to the Italian Association for the Advancement of Science in 1921.

His researches on the chemical action of light, many of them carried out in conjunction with Dr. Silber, are noteworthy. Some of the photochemical actions observed are important but the work is very complex and the results are not always definite.

In addition there are a number of investigations by Ciamician on physical chemistry, some of his earliest work was on the spectra of homologous elements; later researches were on theory of electrolytic dissociation, on the nature of chemical affinity and on the valency of atoms.

From 1910 onwards Ciamician was a member of the Italian senate, where he was interested mainly in matters relating to education and chemical industry. He was a member of practically all the Italian scientific societies and an honorary member of the chemical societies of America, England, France and Germany. A new chemical institute which will bear his name is to be erected at Bologna to commemorate his work.

CIBBER (or **CIBERT**), **CAIUS GABRIEL** (1630–1700), Danish sculptor, was born at Flensburg. He was the son of the king's cabinet-maker, and was sent to Rome at the royal charge while yet a youth. He came to England during the Protectorate, or during the first years of the Restoration. Besides the famous statues of Melancholy and Raving Madness ("great Cibber's brazen brainless brothers"), now in the Guildhall, London, Cibber produced the bas-reliefs round the Monument on Fish street hill. The several kings of England and the Sir Thomas Gresham, ex-

cuted by him for the Royal Exchange, were destroyed with the building itself in 1838. Cibber was long employed by the fourth earl of Devonshire, and many fine specimens of his work are to be seen at Chatsworth. Under that nobleman he took up arms in 1688 for William of Orange, and was appointed, in return, carver to the king's closet. He died rich, and, according to Horace Walpole, built the Danish church in London, where he lies buried beside his second wife, to whom he erected a monument. She was a Miss Colley, of Glaiston, granddaughter of Sir Anthony Colley, and the mother of Colley Cibber.

CIBBER, COLLEY (1671-1757), English actor and dramatist, was born in London on Nov. 6, 1671, the eldest son of Caius Gabriel Cibber, the sculptor. Sent in 1682 to the free school at Grantham, Lincolnshire, the boy distinguished himself by an aptitude for writing verse. He was removed from school in 1687 on the chance of election to Winchester college. His father, however, had not then presented that institution with his statue of William of Wykeham, and the son was rejected, although through his mother he claimed to be of "founder's kin." The boy went to London, and indulged his passion for the theatre. He was on his way to Chatsworth, the seat of William Cavendish, earl (afterwards duke) of Devonshire, for whom his father was then executing commissions, when the news of the landing of William of Orange was received; father and son met at Nottingham, and Colley Cibber was taken into Devonshire's company of volunteers. Afterwards he enrolled himself (1690) as an actor in Betterton's company at Drury Lane. On his more than meagre earnings, which rose to £1 per week, supplemented by an allowance of £20 a year from his father, he contrived to live with his wife and family—he had married in 1693—and to produce a play, *Love's Last Shift, or the Fool in Fashion* (1696). Of this comedy Congreve said that it had "a great many things that were like wit in it"; and Vanbrugh honoured it by writing his *Relapse* as a sequel. Cibber played the part of Sir Novelty Fashion, and his performance as Lord Foppington, the same character renamed, in Vanbrugh's piece established his reputation as an actor. In 1698 he was assailed with other dramatists, by Jeremy Collier in the *Short View*. In Nov., 1702, he produced, at Drury Lane, *She Wou'd and She Wou'd Not; or the Kind Impostor*, one of his best comedies; and in 1704, for himself and Mrs. Oldfield, *The Careless Husband*, which Horace Walpole classed, with Cibber's *Apology*, as "worthy of immortality." In 1706 Cibber left Drury Lane for the Haymarket, but when the two companies united two years later he rejoined his old theatre through the influence of his friend Colonel Brett, a shareholder. Brett made over his share to Wilks, Estcourt and Cibber. Complaints against the management of Christopher Rich led, in 1709, to the closing of the theatre by order of the crown, and William Collier obtained the patent. After a series of intrigues Collier was bought out by Wilks, Doggett and Cibber, under whose management Drury Lane became more prosperous than it ever had been. In 1715 a new patent was granted to Sir Richard Steele, and Barton Booth was also added to the management. In 1717 Cibber produced the *Nonjuror*, an adaptation from Molière's *Tartuffe*; the play, for which Nicholas Rowe wrote an abusive prologue, ran eighteen nights, and the author received from George I., to whom it was dedicated, a present of two hundred guineas. *Tartuffe* became an English Catholic priest who incited rebellion, and there is little doubt that the Whig principles expressed in the *Nonjuror* led to Cibber's appointment as poet laureate (1730). It also provoked the animosity of the Jacobite and Catholic factions, and was possibly one of the causes of Pope's hostility to Cibber. Numerous "keys" to the *Nonjuror* appeared in 1718. In 1726 Cibber pleaded the cause of the patentees against the estate of Sir Richard Steele before Sir Joseph Jekyll, master of the rolls, and won his case. In 1730 Mrs. Oldfield died, and her loss was followed in 1732 by that of Wilks; Cibber now sold his share in the theatre, appearing rarely on the stage thereafter. In 1740 he published *An Apology for the Life of Colley Cibber, Comedian . . . with an Historical View of the Stage during his Own Time*, which gives the best account there is of Cibber's contemporaries on the London stage.

In 1742 Cibber was substituted for Theobald as the hero of

Pope's *Dunciad*. Cibber had introduced some gag into the *Rehearsal*, in which he played the part of Bayes, referring to the ill-starred farce of *Three Hours after Marriage* (1717). This play was nominally by Gay, but Pope and Arbuthnot were known to have had a hand in it. Cibber refused to discontinue the offensive passage, and Pope revenged himself in sarcastic allusions in his printed correspondence, in the *Epistle to Dr. Arbuthnot* and in the *Dunciad*. To these Cibber replied with *A Letter from Mr. Cibber to Mr. Pope, inquiring into the motives that might induce him in his satirical works to be so frequently fond of Mr. Cibber's name* (1742). Cibber scored with an "idle story of Pope's behaviour in a tavern" inserted in this letter, and gives an account of the original dispute over the *Rehearsal*. By the substitution of Cibber for Theobald as hero of the *Dunciad* much of the satire lost its point. Cibber's faults certainly did not include dullness. A new edition contained a prefatory discourse, probably the work of Warburton, entitled "Ricardus Aristarchus, or the Hero of the Poem," in which Cibber is made to look ridiculous from his own *Apology*. Cibber replied in 1744 with *Another Occasional Letter . . .*, and altogether he had the best of the argument. When he was 74 years old he made his last appearance on the stage as Pandulph in his own *Papal Tyranny in the Reign of King John* (Covent Garden, Feb. 15, 1745), a miserable paraphrase of Shakespeare's play. He died on Dec. 11, 1757.

Cibber's reputation has suffered unduly from the depreciation of Pope and Johnson. "I could not bear such nonsense" said Johnson of one of Cibber's odes, "and I would not let him read it to the end." Fielding attacked Cibber's style and language more than once in *Joseph Andrews*, and elsewhere. Nevertheless, Cibber possessed wit, unusual good sense and tact; and in the *Apology* he showed himself the most delicate and subtle critic of acting of his time. He was frequently accused of plagiarism, and did not scruple to make use of old plays, but he is said to have been ashamed of his Shakespearian adaptations, one of which, however, *Richard III.* (Drury Lane, 1700), kept its place as the acting version until 1821. Cibber is rebuked for his mutilation of Shakespeare by Fielding in the *Historical Register for 1736*, where he figures as Ground Ivy.

CHARLOTTE, Colley Cibber's youngest daughter, married Richard Charke, a violinist, from whom she was soon separated. She began as an understudy to actresses in leading parts, but quarrelled with her manager, Charles Fleetwood, on whom she wrote a one-act skit, *The Art of Management* (1735). She also wrote two comedies and two novels of small merit, and an untrustworthy, but amusing, *Narrative of Life of . . . Charlotte Charke, . . . by herself* (1755), reprinted in Hunt and Clarke's *Autobiographies* (1822).

The *Apology* was edited in 1822 by E. Bellchambers and in 1889 by R. W. Lowe, who printed with it other valuable theatrical books and pamphlets. It is also included in Hunt and Clarke's *Autobiographies* (1826, etc.). Cibber's *Dramatic Works* were published in 1760, with an account of the life and writings of the author, and again in 1777. Besides the plays already mentioned, he wrote *Woman's Wit, or the Lady in Fashion* (1697), which was altered later (1707) into *The Schoolboy, or the Comical Rivals*; *Xerxes* (1699), a tragedy acted only once; *The Provoked Husband* (acted 1728), completed from Vanbrugh's unfinished *Journey to London*; *The Rival Queens, with the Humours of Alexander the Great* (acted 1710), a comical tragedy; *Damon and Phyllida* (acted 1729), a ballad opera; and adaptations from Beaumont and Fletcher, Dryden, Molière and Corneille. A bibliography of the numerous skits on Cibber is to be found in Lowe's *Bibliographical Account of English Theatrical Literature*.

CIBBER, SUSANNAH MARIA (1714-1766), wife of T. Cibber, was an actress of distinction. She was the daughter of a Covent Garden upholsterer, and sister of Dr. Arne (1710-78) the composer. Mrs. Cibber had a beautiful voice and began her career in opera. She was the original Galatea in Handel's *Acis and Galatea*, and the contralto arias in the *Messiah* are said to have been written for her. She played Zarah in Aaron Hill's version of Voltaire's *Zaïre* in 1736, and it was as a tragic actress, not as a singer, that her greatest triumphs were won. From Colley Cibber she learned a sing-song method of declamation. Her mannerisms, however, did not obscure her real genius, and she freed herself from them entirely when she began to act with Garrick, with whom she

was associated at Drury Lane from 1753. She died on Jan. 30, 1766. She married Theophilus Cibber in 1734, but soon separated from him. Appreciations of Mrs. Cibber's fine acting are to be found in many contemporary writers, one of the most discriminating being in the *Rosciad* of Charles Churchill.

CIBBER, THEOPHILUS (1703–1758), Colley Cibber's son; also an actor and playwright, was born on Nov. 26, 1703. In 1734 he was acting-manager at the Haymarket, and later played at Drury Lane, Lincoln's Inn Fields and Covent Garden. His best impersonation was as Pistol, but he also distinguished himself in some of the fine-gentleman parts affected by his father. He was one of the ringleaders in the intrigues against John Highmore, who had bought a share in the patent of Drury Lane from Colley Cibber. Theophilus Cibber, with a number of other actors, seceded from Drury Lane, and in thus depreciating the value of the patent, for which his father had received a considerable sum, acted with doubtful honesty. He contemplated the publication of an autobiography, but was effectually dissuaded by the appearance (1740) of a scathing account of his career by an unknown author, entitled *An Apology for the Life of Mr. T. . . . C. . . . supposed to be written by himself*. In 1753 he began *The Lives and Characters of the most Eminent Actors and Actresses of Great Britain and Ireland*, but he went no further than the life of Barton Booth. He wrote some plays of no great merit. In 1753 appeared *An Account of the Lives of the Poets of Great Britain and Ireland*, with the name of "Mr. Cibber" on the title page. The five volumes of *Lives* are chiefly based on the earlier works of Gerard Langbaine and Giles Jacob and the ms. collections of Thomas Coxeter (1689–1747). The book is said to have been largely written by Robert Shiels, Dr. Johnson's amanuensis. Theophilus Cibber perished by shipwreck on his way to Dublin to play at the Theatre Royal.

CIBORIUM, in classical Latin a drinking-vessel (Gr. *κύβριον*, the cup-shaped seed-vessel of the Egyptian water-lily, and hence a cup). In the early Christian Church the *ciborium* was a canopy over the altar (*q.v.*), supported on columns, and from it hung the dove-shaped receptacle in which was reserved the consecrated Host. The name was early transferred to the receptacle, and in the Western Church the canopy was known as a baldachin (Ital. *baldacchino*, from *Baldacco*, Bagdad, whence came the rich brocade used for canopies, etc.). At the present day in the Roman Church the term "pyx" (*πύξ*, a boxwood vessel) is used for the receptacle in which the viaticum is carried to the sick or dying. Mediaeval pyxes and ciboria are often beautiful examples of the goldsmith's, enameller's and metal-worker's craft. They take most usually the shape of a covered chalice or of a cylindrical box with cover surmounted by a cross. An exquisite ciborium, probably of English 13th century make, fetched £6,000 at Christie's in 1908: copper-gilt, ornamented with champlevé enamels, with Biblical subjects in medallions on the outside (coloured illustration in catalogue of Burlington Fine Arts Club Exhibition, 1897).

CIBRARIO, LUIGI, COUNT (1802–1870), Italian statesman and historian, was born in Ussegia. His verses to King Charles Albert, then prince of Carignano, on the birth of his son Victor Emmanuel, led to a long friendship. He entered the Sardinian civil service, and in 1824 was appointed lecturer on canon and civil law. He was sent to search the archives of Switzerland, France and Germany for charters relating to the history of Savoy. During the war of 1848, after the expulsion of the Austrians from Venice, Cibrario was sent to that city with Colli on an abortive mission to secure its union with Piedmont. After the battle of Novara (1849) and the abdication of Charles Albert he visited the ex-king at Oporto on behalf of the Senate. In May 1852 he became minister of finance in the reconstructed d'Azeglio cabinet, and later minister of education in that of Cavour. He strongly supported Cavour's Crimean policy (1855), and, as minister for foreign affairs during the war, he seconded Cavour in procuring the admission of Piedmont to the congress of Paris on an equal footing with the great Powers. On retiring from the foreign office Cibrario was created count. After the war of 1866 by which Austria lost Venetia, Cibrario negotiated the restitution of State papers and art treasures removed by the Austrians from Lom-

bardy and Venetia to Vienna. He died in Oct. 1870, near Salò, on the lake of Garda. His most important work was his *Economia politica del medio evo* (Turin, 1839), popular then, but now of little value. His *Schiavitù e servaggio* (Milan, 1868–69) gave an account of the development and abolition of slavery and serfdom.

His biography has been written by F. Odorici, *Il Conte L. Cibrario* (Florence, 1872).

CICADA (*Cicadidae*), insects of the homopterous division of the Hemiptera (*q.v.*), generally of large size with the femora of the fore legs spined below, two pairs of large membranous wings and prominent eyes. Cicadas are remarkable for the shrill noise emitted by the males, which has been variously compared to a knife-grinder, scissors-grinder or even a railway whistle, and may be heard in concert at a distance of a quarter of a mile or more. The sound-producing organs are a kind of drum on each side of the base of the abdomen. These drums vibrate by the action of powerful muscles and the sound can be modified by the so-called mirrors or sounding boards. Although no auditory organs are known in the females, the song of the males is regarded as a sexual call.

One of the best-known species is the periodical cicada (*Tibicen septendecim*) of N. America, often known as the 17-year "locust" which appears in great numbers after long intervals. Its periodical appearance is due to the nymphs requiring often as long as 17 years for their development, and to the fact that the adults of one generation appear about the same time in vast numbers. By means of a saw-like instrument the eggs are laid in the twigs of trees, and the nymphs, upon hatching, drop to the ground, where they bury themselves. They feed by sucking juices from the roots of forest and fruit trees and finally change into the so-called "pupae." In the latter stage the insect crawls from the ground and, grasping a suitable support, allows of the emergence of the fully-fledged cicada. In some cases these "pupae" construct curious earthen chimneys wherein they live before turning into adults. The life-histories of cicadas are all very similar, but few are so long-lived as the species alluded to. Over 1,000 kinds are known and they are most abundant in the tropics. One species occurs in the southern counties of England, but is rare; 74 species are known in the United States. See J. G. Myers, *Insect Singers: a Natural History of the Cicadas* (1929).

CICELY, *Myrrhis odorata* (family Umbelliferae), a perennial herb with a leafy hollow stem, 2 to 3 ft. high, much divided leaves, whitish beneath, a large sheathing base, and terminal umbels of small white flowers, the outer ones only of which are fertile. The fruit is dark brown, long ($\frac{3}{4}$ to 1 in.), narrow and beaked. The plant is a native of central and southern Europe, and is found in parts of England and Scotland in pastures, usually near houses. It has aromatic and stimulant properties and was formerly used as a pot-herb.

CICERO, the name of two families of ancient Rome. It may perhaps be derived from *cicer* (pulse), in which case it would be analogous to such names as *Lentulus*, *Tubero*, *Piso*. Of one family, of the plebeian Claudian gens, only a single member, Gaius Claudius Cicero, tribune in 454 B.C., is known. The other family was a branch of the Tullii, settled from an ancient period at Arpinum. This family, four of whose members are noticed specially below, did not achieve more than municipal eminence until the time of M. Tullius Cicero, the great orator.

(1) **MARCUS TULLIUS CICERO** (106–43 B.C.), Roman orator and politician, was born at Arpinum on Jan. 3, 106 B.C. His mother, Helvia, is said to have been of good family. His father was by some said to have been descended from Attius Tullius, the Volscian host of Coriolanus, while spiteful persons declared him to have been a fuller; in any case he was a Roman knight with property at Arpinum and a house in Rome. His health was weak, and he generally lived at Arpinum, where he devoted himself to literary pursuits. Cicero spent his boyhood partly in his native town and partly at Rome. The poet Archias, he says, first inspired him with the love of literature. He was much impressed by the teaching of Phaedrus, the Epicurean, at a period before he assumed the *toga virilis*; he studied dialectic under Diodotus the Stoic, and in 88 B.C. attended the lectures of Philo, the head of the Academic school, whose devoted pupil he became.

He studied rhetoric under Molo (Molon) of Rhodes, and law under the guidance of Q. Mucius Scaevola, the augur and juriconsult. After the death of the augur, he transferred himself to the care of Q. Mucius Scaevola, the *pontifex maximus*, a still more famous juriconsult, nephew of the augur. His literary education at this period consisted largely of verse-writing and making translations from Greek authors. We hear of an early poem named *Pontius Glaucus* the subject of which is uncertain, and of translations of Xenophon's *Oeconomica* and the *Phaenomena* of Aratus. Considerable fragments of the latter work are still extant. To this period also belongs his *de Inventione rhetorica*, of which he afterwards spoke lightly (*de Orat.* i. 5), but which enjoyed a great vogue in the middle ages. Cicero also, according to Roman practice, received military training. At the age of 17 he served in the social war successively under Pompeius Strabo and Sulla (89 B.C.). In the war between Marius and Sulla his sympathies were with Sulla, but he did not take up arms (*Sext. Rosc.* 136, 142).

His forensic life begins in 81 B.C., at the age of 25. A speech delivered in this year, *pro Quinctio*, is still extant; it is concerned with a technical point of law and has little literary merit. In the following year he made his celebrated defence of Sextus Roscius on a charge of parricide. He subsequently defended a woman of Arretium, whose freedom was impugned on the ground that Sulla had confiscated the territory of that town. He then left Rome on account of his health, and travelled for two years in the East. He studied philosophy at Athens under various teachers, notably Antiochus of Ascalon, founder of the Old Academy, a combination of Stoicism, Platonism and Peripateticism. In Asia he attended the courses of Xenocles, Dionysius and Menippus, and in Rhodes those of Posidonius, the famous Stoic. In Rhodes also he studied rhetoric once more under Molo, to whom he ascribes a decisive influence upon the development of his literary style. He had previously affected the florid, or Asiatic, style of oratory then current in Rome. The chief faults of this were excess of ornament, antithesis, alliteration and assonance, monotony of rhythm, and the insertion of words purely for rhythmical effect. Molo, he says, rebuked his youthful extravagance and he came back "a changed man."
